2.5 Local and Regional Legislation ................................................................. 2-21
  2.5.1 Cultural Heritage Sites of Regional Importance ................................. 2-21
  2.5.2 Red Data Book of the Krasnodar Krai ................................................. 2-22

2.6 International and Regional Environmental and Social Conventions and Treaties ................................. 2-22
  2.6.1 Espoo Convention .............................................................................. 2-22
  2.6.2 Bucharest Convention ........................................................................ 2-23

2.7 Standards and Guidelines for International Financing .............................. 2-33
  2.7.1 Equator Principles III ................................................................. 2-33
  2.7.2 OECD Common Approaches, 2012 .................................................... 2-37
  2.7.3 Japan Bank for International Cooperation (JBIC) Environmental Guidelines ......................................................... 2-38
  2.7.4 International Finance Corporation Performance Standards .................. 2-38

3 Impact Assessment Methodology ................................................................. 3-1
  3.1 Introduction ......................................................................................... 3-1
  3.2 ESIA Process ........................................................................................ 3-1
    3.2.1 Screening ....................................................................................... 3-3
    3.2.2 ESIA Scoping ............................................................................... 3-6
    3.2.3 Additional Baseline Field Surveys and Studies ................................. 3-8
  3.3 Impact Assessment Framework .............................................................. 3-8
    3.3.1 Activities and Impacts ............................................................... 3-9
    3.3.2 Impacts Nature and Type ............................................................... 3-11
    3.3.3 Impact Magnitude ....................................................................... 3-12
    3.3.4 Receptor Sensitivity (Resilience and Value) .................................... 3-13
    3.3.5 Impact Significance ....................................................................... 3-13
    3.3.6 Waste ......................................................................................... 3-15
    3.3.7 Unplanned Events ........................................................................ 3-15
    3.3.8 Cumulative Impacts ..................................................................... 3-15
    3.3.9 Transboundary Impacts ............................................................... 3-17
    3.3.10 Impact Mitigation ........................................................................ 3-17
    3.3.11 Residual Impact Assessment ......................................................... 3-18
    3.3.12 Environmental and Social Management Plans ............................... 3-19
  3.4 Stakeholder Engagement ....................................................................... 3-19
  3.5 Data Limitations ................................................................................... 3-20

4 Analysis of Alternatives ............................................................................ 4-1
  4.1 Introduction .......................................................................................... 4-1
  4.2 Approach to Analysis of Alternatives ..................................................... 4-2
  4.3 Zero Alternative .................................................................................... 4-3
  4.4 South Stream Offshore Pipeline Alternatives ........................................... 4-3
    4.4.1 Alternative Means of Gas Transportation ........................................ 4-3
    4.4.2 Offshore (Macro) Routing .............................................................. 4-4
4.5 Project Alternatives ............................................................................................. 4-8
4.5.1 Landfall Site Selection ............................................................................. 4-8
4.5.2 Shoreline Crossing .................................................................................. 4-9
4.5.3 Onshore Routing ................................................................................... 4-14
4.5.4 Offshore Route Optimisation ................................................................. 4-14
4.6 Summary .......................................................................................................... 4-23

5 Project Description.............................................................................................. 5-1
5.1 Introduction ........................................................................................................ 5-1
5.2 Project Components .......................................................................................... 5-2
5.2.1 Project Area ............................................................................................ 5-3
5.2.2 Associated Facilities ................................................................................. 5-4
5.2.3 The Russkaya Compressor Station ............................................................ 5-9
5.2.4 Pipeline Routing, Spacing and Operational Exclusion Zones ................... 5-11
5.2.5 Permanent Landfall Facilities ................................................................. 5-12
5.2.6 Design Philosophy ................................................................................. 5-21
5.2.7 Resource Efficiency ............................................................................... 5-28
5.3 Construction Phase ............................................................................................ 5-28
5.3.1 Indicative Construction Schedule ............................................................ 5-28
5.3.2 Logistics and Material Supply ................................................................. 5-30
5.3.3 Onshore Access Routes ......................................................................... 5-31
5.3.4 Construction of Landfall Section ............................................................. 5-36
5.3.5 Construction of Nearshore Section ......................................................... 5-87
5.3.6 Construction of Offshore Section .......................................................... 5-106
5.4 Pre-Commissioning Phase ............................................................................... 5-136
5.4.1 Overview ............................................................................................ 5-136
5.4.2 Landfall and Nearshore Section Pipeline Testing and Pre-commissioning (Hydrotesting) ........................................................................ 5-138
5.4.3 Landfall Facilities Testing and Pre-commissioning (Hydrotesting) ...... 5-142
5.4.4 Cleaning, Gauging and Drying of Whole South Stream Offshore Pipeline 5-148
5.4.5 Summary of Waste / Discharges and Emissions Generated during Pre-Commissioning ................................................................. 5-150
5.5 Commissioning .............................................................................................. 5-153
5.5.1 Temporary Gas Heating Requirements .................................................. 5-154
5.5.2 Pipeline Gas Injection with a PIG ......................................................... 5-155
5.5.3 Pipeline Gas Injection without a PIG ..................................................... 5-156
5.5.4 Pipeline Pressurisation ........................................................................... 5-156
5.6 Operational Phase ............................................................................................ 5-156
5.6.1 South Stream Offshore Pipeline Operating Philosophy ........................ 5-156
5.6.2 Pipeline Shut Down and Restart Process ............................................... 5-156
5.6.3 Maintenance ....................................................................................... 5-163
5.6.4 Landfall Facilities ................................................................................ 5-165
5.6.5 Emergency Pipeline Repair ................................................................... 5-166
5.6.6 Land Use during the Operational Phase ................................................. 5-167

13 Landscape and Visual

13.1 Introduction

13.2 Scoping

13.3 Spatial and Temporal Boundaries

13.4 Baseline Data

13.4.1 Methodology and Data

13.4.2 Secondary Data

13.4.3 Data Gaps

13.4.4 Primary Data and Baseline Surveys

13.4.5 Data Assumptions and Limitations

13.5 Baseline Characteristics

13.5.1 Context

13.5.2 Existing Landscape and Seascape of the Survey Area

13.5.3 Landscape and Seascape Character

13.5.4 Visual Amenity

13.5.5 Baseline Summary

13.6 Impact Assessment

13.6.1 Impact Assessment Methodology

13.6.2 Assessment of Potential Impacts: Construction and Pre-Commissioning

13.6.3 Assessment of Potential Impacts: Operational (including Commissioning) Phase

13.6.4 Assessment of Potential Impacts: Decommissioning Phase

13.7 Unplanned Events

13.8 Cumulative Impacts Assessment

13.9 Conclusions

14 Socio-Economics

14.1 Introduction

14.1.1 Structure of Socio-Economics Chapter

14.1.2 Human Rights Due Diligence

14.1.3 Relationship to the Community Health, Safety and Security Impact Assessment

14.1.4 Relationship to Other Chapters

14.2 Scoping and Stakeholder Consultation

14.2.1 Impacts Identified During Scoping

14.2.2 Post-Scoping Stage Revisions

14.3 Spatial and Temporal Boundaries

14.3.1 The Project Area and Project Sections

14.3.2 Location

14.3.3 Study Area and Zone of Influence

14.4 Methodology and Data

14.4.1 Data Sources
15.4 Methodology and Data ....................................................................................... 15-8
  15.4.1 Primary Data and Surveys ........................................................................ 15-8
  15.4.2 Secondary Data ......................................................................................... 15-8
  15.4.3 Stakeholder Engagement .......................................................................... 15-11
  15.4.4 Data Assumptions, Limitations and Gaps .................................................. 15-11

15.5 Community Health, Safety and Security Baseline ........................................... 15-12
  15.5.1 Demographic Community Profile .......................................................... 15-12
  15.5.2 Known Community Issues ....................................................................... 15-13
  15.5.3 Baseline Data by Determinant of Health .................................................. 15-29
  15.5.4 Emergency and Disaster Response ......................................................... 15-36

15.6 Legal and Policy Context .................................................................................. 15-36
  15.6.1 IFC Performance Standards (PS) .............................................................. 15-36
  15.6.2 National Legislation ................................................................................ 15-37
  15.6.3 Regional / Local Policy ............................................................................ 15-38

15.7 Impact Assessment Methodology ..................................................................... 15-39
  15.7.1 Methodology .......................................................................................... 15-39
  15.7.2 Determinants of Health .......................................................................... 15-40
  15.7.3 Receptor Sensitivity ................................................................................ 15-41
  15.7.4 Impact Magnitude .................................................................................. 15-44
  15.7.5 Impact Significance Criteria .................................................................... 15-44
  15.7.6 Impact Mitigation .................................................................................... 15-45

15.8 Assessment of Potential Impact: Community Health, Safety and Security ............ 15-46
  15.8.1 Impact Assessment: Construction and Pre-Commissioning Phase ............ 15-49
  15.8.2 Impact Assessment: Operational Phase .................................................. 15-77
  15.8.3 Impact Assessment: Decommissioning .................................................... 15-82

15.9 Occupational Health and Safety ....................................................................... 15-83

15.10 Unplanned Events ......................................................................................... 15-83

15.11 Cumulative Impacts ...................................................................................... 15-83

15.12 Conclusion ..................................................................................................... 15-83

16 Cultural Heritage ............................................................................................... 16-1
  16.1 Introduction .................................................................................................. 16-1
  16.2 Scoping ......................................................................................................... 16-2
  16.3 Spatial and Temporal Boundaries .................................................................. 16-3
    16.3.1 Terrestrial Cultural Heritage Study and Survey Areas ........................... 16-4
    16.3.2 Marine Cultural Heritage Study and Survey Areas .............................. 16-5
  16.4 Baseline Data ............................................................................................... 16-7
    16.4.1 Methodology and Data .......................................................................... 16-7
    16.4.2 Secondary Data ...................................................................................... 16-7
    16.4.3 Data Gaps ............................................................................................. 16-15
    16.4.4 Primary Data/Baseline Surveys ............................................................... 16-16
    16.4.5 Data Assumptions and Limitations ....................................................... 16-20
16.5 Baseline Characteristics ................................................................. 16-22
  16.5.1 Overview ............................................................................. 16-22
  16.5.2 Archaeological and Historical Context – Terrestrial and Marine ... 16-25
  16.5.3 Intangible Cultural Heritage ..................................................... 16-37
  16.5.4 Baseline Summary ................................................................. 16-40
  16.5.5 Critical Cultural Heritage ....................................................... 16-57
  16.5.6 Palaeontological Heritage ....................................................... 16-57

16.6 Impact Assessment ........................................................................ 16-58
  16.6.1 Impact Assessment Methodology ............................................. 16-58
  16.6.2 Impact Assessment Criteria .................................................... 16-63
  16.6.3 Assessment of Potential Impacts: All Phases ......................... 16-72

16.7 Mitigation and Monitoring ............................................................. 16-84
  16.7.1 Mitigation Measures – Construction and Pre-Commissioning Phase 16-87
  16.7.2 Mitigation Measures – Commissioning and Operational Phase .... 16-90
  16.7.3 Monitoring Requirements ....................................................... 16-90

16.8 Residual Impact Assessment – All Phases ...................................... 16-91
  16.8.1 Terrestrial Cultural Heritage ................................................... 16-91
  16.8.2 Marine Cultural Heritage ....................................................... 16-93
  16.8.3 Summary of Cultural Heritage Residual Impact ...................... 16-95

16.9 Unplanned Events ......................................................................... 16-106

16.10 Cumulative Impacts ..................................................................... 16-106

16.11 Conclusions ............................................................................... 16-106

17 Ecosystem Services .......................................................................... 17-1
  17.1 Introduction ............................................................................... 17-1
  17.2 Approach .................................................................................. 17-6
  17.3 Scoping ..................................................................................... 17-8
  17.4 Spatial and Temporal Boundaries .............................................. 17-22
    17.4.1 Project Area ........................................................................ 17-23
    17.4.2 Affected Ecosystems ............................................................ 17-23
    17.4.3 Affected Beneficiaries .......................................................... 17-31
    17.4.4 Temporal Boundaries ........................................................... 17-32
  17.5 Baseline Data ............................................................................ 17-35
    17.5.1 Methodology and Data ......................................................... 17-35
    17.5.2 Secondary Data .................................................................. 17-35
    17.5.3 Data Gaps .......................................................................... 17-35
    17.5.4 Primary Data and Baseline Surveys ...................................... 17-36
    17.5.5 Data Assumptions and Limitations ...................................... 17-36
  17.6 Baseline Characteristics ............................................................... 17-37
    17.6.1 Crops ............................................................................... 17-37
    17.6.2 Capture Fisheries ................................................................. 17-43
    17.6.3 Water Supply ..................................................................... 17-46
17.6.4 Hazard Regulation .............................................................................. 17-51
17.6.5 Air Quality Regulation ........................................................................ 17-53
17.6.6 Water Quality Regulation .................................................................... 17-55
17.6.7 Soil Quality Regulation ....................................................................... 17-57
17.6.8 Tourism and Recreation Values ............................................................ 17-58
17.6.9 Cultural and Spiritual Values ............................................................... 17-64
17.6.10 Wild Species Diversity ...................................................................... 17-66
17.6.11 Baseline Summary ............................................................................ 17-71

17.7 Impact Assessment ......................................................................................... 17-73
17.7.1 Impact Assessment Methodology ........................................................... 17-73
17.7.2 Assessment of Potential Impacts: Construction and Pre-Commissioning . 17-78
17.7.3 Assessment of Potential Impacts: Operational Phase ......................... 17-122
17.7.4 Assessment of Potential Impacts: Decommissioning Phase ............... 17-129

17.8 Unplanned Events ......................................................................................... 17-140

Glossary

Aarhus Convention
An international legal agreement that promotes access to information, public participation in decision making and access to justice in environmental matters.

Abyssal Plain
The deep, flat sea floor that lies between continental margins i.e. the continental shelves and slopes (and other significant features such as mid-ocean ridges and deep ocean trenches).

Acceptance or Approval
The instruments of "acceptance" or "approval" of a treaty have the same legal effect as ratification and consequently express the consent of a state to be bound by a treaty.1

Accession
"Accession" is the act whereby a state accepts the offer or the opportunity to become a party to a treaty already negotiated and signed by other states. It has the same legal effect as ratification. Accession usually occurs after the treaty has entered into force.

Acoustic Reflectivity
Sound energy (via sonar) reflected from a surface. The relative reflectivity of a specific material, that is, the tendency to deflect sound energy in a specific medium rather than absorb it.

Acoustic Target
Potential man-made features and localised obstructions present on the sea floor, identified from analysis of acoustic data files, defined according to their spatial extent, configuration, location and environmental context.

Affected Party/Parties
A country involved in a transnational linear project whose territory may be significantly adversely affected by the activity in a Party of Origin. See Party of Origin below.

Aleurite
Silt

Algae
Algae are photosynthetic organisms that occur in the sea, in freshwater and moist habitats on land. They vary from small, single-celled forms (e.g. phytoplankton) to complex multicellular forms (seaweeds).

Alien Species / Invasive Species
A species not native to the environment it inhabits.

Alluvial
Soils carried by water and deposited according to size and specific gravity as the flow rate decreases.

Ambient Air Quality Limits
Ambient air quality limits are are concentrations or air quality indicators recorded over a given time period, which are considered to be acceptable in terms of what is scientifically known about their effects on health and on the environment. They can be used as a benchmark to indicate whether air quality is being degraded.

Ambient Levels
Sharing the same physical and/or chemical properties as the immediate surroundings.

1  http://treaties.un.org/Pages/Overview.aspx?path=overview/glossary/page1_en.xml
Anadromous
Fish that migrate up rivers from the sea to breed in fresh water.

Anaerobic
Relating to the absence of free oxygen.

Anionic Surfactant
Chemicals that act as a surface agent to reduce the surface tension of liquids. Commonly used in synthetic detergents but also used in industrial processes such as plastic and paint manufacture.

Annulus
The area between a pair of concentric circles. For the purposes of this document, annulus refers to the space between the microtunnel lining and the pipeline.

Anoxic
Absence of oxygen.

Anthropogenic
Relating to, or resulting from, the influence of human activity on the environment.

Archaeology
The scientific study of the physical evidence of past human societies recovered through collection, artefact analysis, and excavation. Archaeologists not only attempt to discover and describe past cultures but also to formulate explanations for the development of cultures. Conclusions drawn from study and analyses provide answers and predictions about human behaviour that add, complement, and sometimes correct the written accounts of history and prehistory.

Archaeological Context
The physical setting, location, and cultural association of artefacts and features within an archaeological site.

Archaeological Excavation
A programme of controlled, intrusive fieldwork with defined research objectives which examines and records archaeological deposits, features and structures and, as appropriate, retrieves artefacts, environmental evidence and other remains within a specified area or site (on land or underwater). The records made and objects gathered during fieldwork are studied and the results of that study published in detail appropriate to the project design and the significance of the results.

Archaeological Sites
Locations with physical evidence for where people once lived, hunted, farmed, camped, held ceremonies or were buried.

Artefact
An object or part of an object that has been used or created by a human and provides physical clues to the activity carried out by humans in the area of discovery. These include worked stone tools and tool-making waste, bone, pottery and metalwork.

Artisanal Fishery
A fishery involving fishing households (as opposed to commercial companies), using relatively small amount of capital and energy, relatively small fishing vessels (if any), making short fishing trips, close to shore, with the catch being sold, bartered to traded mainly for local consumption (including that of the fishing households).

ART Municipal District
The entire municipal district area known as Anapa Resort Town (ART) including the
town of Anapa (urban district) and 11 other rural districts including Supsekh Rural District and Gai Kodzor Rural District.

Assemblage
A group of artefacts related to each other based upon their recovery from a common archaeological context.

Associated Facility
Defined by IFC PS 1 as: "facilities that are not funded as part of the project and that would not have been constructed or expanded if the project did not exist and without which the project would not be viable ".

Atmospheric Dispersion Model
A computer model used to assess air quality impacts. The model uses local meteorological data to enable a realistic assessment of dispersion from the emission sources for weather conditions that are applicable to the site.

Autonomous Underwater Vehicle (AUV)
A robot which travels underwater without requiring input from an operator. AUVs constitute part of a larger group of undersea systems known as unmanned underwater vehicles.

Authigenic Mineral
A mineral that was generated where it was found or observed – i.e formed in situ.

Automatic monitoring station
A type of monitoring equipment that continuously measures air quality parameters. Air is pumped into a series of analysers and the air quality parameter concentrations are recorded. The data are stored by a data logger and accessed remotely by a computer and modem.

Average Permissible Concentration
The annual average quantity/unit of volume of an air quality indicator that is not considered an undue risk to human health and the environment, in accordance with national legislation in the Russian Federation.

Backfill
Material used to refill an excavated area.

Bacterioplankton
The bacterial component of the plankton.

Bar
Metric unit of atmospheric pressure.

Base Case Design
The base case design is the default Project design, and is reached following the consideration of alternative designs in relation to technical, environmental and socio-economic factors.

Baseflow
Contribution of groundwater flow to surface water flow.

Baseline
Term used to describe existing conditions of the physical, biological, socio-economic, and cultural heritage environmental aspects. The ESIA processes assesses likely impacts on baseline conditions.

Baseline Data
Data gathered during the Environmental and Social Impact Assessment and used to describe the relevant existing conditions (see ‘Baseline’).

Benthic
Of or relating to the bottom of a sea, lake, or other body of water.
Benthic Sediments
Sediment found at the bottom of a water column.

Benthopelagic
Living and feeding near the bottom as well as in mid-water or near the surface. Feeding on benthic as well as free swimming organisms.

Benthos
Flora and fauna organisms that live on/in sediment at the bottom of a water column.

Bentonite
A natural, inert, non-toxic clay used as a filler, sealing or suspending agent.

Benzene
Benzene is an organic chemical compound with the molecular formula C6H6. It is a colourless, flammable, sweet-smelling liquid which is a natural constituent of crude oil (diesel and petrol).

Biodiversity
A term used to describe aspects of biological diversity, especially including species richness, ecosystem complexity and genetic variation.

Biological Communities
An ecological unit composed of various populations of different organisms found living together in a particular environment.

Biomass
The total mass of living matter present in an ecosystem or at a particular trophic level in a food chain and usually expressed as dry weight or more accurately, as the carbon, nitrogen, or calorific content per unit area.

Biota
The plant and animal life occupying a place together.

Biotope
An area that is uniform in environmental conditions and in its distribution of animal and plant life.

Bivalve
A marine or freshwater mollusc having a laterally compressed body and a shell consisting of two hinged valves.

Block Valve
A valve installed at various strategic locations along a pipeline to enable a segment of the pipeline to be isolated for maintenance work or in case of a rupture or leak.

Blue Stream Pipeline
A pipeline crossing the Black Sea and carrying natural gas from Russia to Turkey. The pipeline runs from the Beregovaya Compressor Station at Arkhipo-Osipovka on the Black Sea Coast of Russia to the Durusu Terminal near Samsun in Turkey.

Bronze Age
The prehistoric period following the Stone Age and preceding the iron Age characterized by the use of weapons and implements made of bronze and by intense trading activity. It is generally dated from around 3000 BC.

Byzantine
Of or relating to the Byzantine Empire that ended in 1453, the empire in southeastern Europe and Asia Minor formed from the eastern part of the Roman Empire.
**Calcareous Argillites**

Calcareous Argillites are a fine grained sedimentary rock that is composed of predominantly clay sized particles (and variable amounts of silt sized particles) containing a high proportion of calcium carbonate typically deposited in shallow water near land as muds and oozes, and then lithified (compacted and cemented) to form a well-formed and relatively hard type of mudstone.

**Calcareous Marls**

Calcareous Marls are a fine grained sedimentary rock that is composed of variable amounts of clay and silt particles and contains a high proportion of calcium carbonate or lime-rich mud. The marl is softer and contains a higher proportion of carbonate material than a Calcareous Argillite.

**Cancun Agreement**

The agreements, reached on December 11 in Cancun, Mexico, at the 2010 United Nations Climate Change Conference represent key steps forward in capturing plans to reduce greenhouse gas emissions and to help developing nations protect themselves from climate impacts and build their own sustainable futures.

**Carbon monoxide (CO)**

Carbon monoxide is a colourless, odourless, and tasteless gas that is slightly lighter than air. It is toxic to humans and animals when encountered in higher concentrations.

**Carcinogenic**

An agent directly involved in causing cancer.

**Cathodic Protection System**

A method of neutralising the corrosive static electric charges in a submerged steel structure.

**Cetacea**

Whales, dolphins and porpoises.

**Chance Find**

An archaeological site or object that was unknown prior to discovery during construction (despite best efforts to identify all sites prior to construction through cultural heritage surveys).

**Chance Find Procedure**

Chance find procedure is a project-specific procedure that outlines what will happen if previously unknown physical resources are encountered during project construction or operation. The procedure includes record keeping and expert verification procedures, chain of custody instructions for movable finds, and clear criteria for potential temporary work stoppages that could be required for rapid disposition of issues related to the finds.

**Chora**

Agricultural hinterland of a Greek city (Greek: χώρα).

**Coccolithophore**

Planktonic flagellate algae with a layer of minute calcareous plates that can form algal blooms colouring the seawater white.

**Colluvial**

Soils deposited at the base of hill slopes or cliffs through the action of gravity.

**Commissioning**

Process by which equipment is tested to verify if it functions according to its design objectives or specifications.

**Comment Form**

A paper form through which stakeholders can submit written comments, views and opinions. Comment forms are distributed
at public consultation meetings and made available in locations where ESIA documentation is disclosed and made available for comments.

Compression

The raising of pressure within a substance.

Compressor Station

To ensure that the natural gas flowing through a pipeline remains pressurised, its compression is required periodically along the pipeline. This is accomplished by compressor stations. Compressor stations increase or raise the pressure of the natural gas using gas compression facilities and equipment.

Conservation

The measures taken to extend the life of cultural heritage in ways that will best sustain its significance and heritage values (ICCROM 1998).

Consultation

The process of formally consulting or discussing a subject. For the purposes of this document, consultation involves two-way communication between the project developers and affected or interested stakeholders.

Contamination

The introduction by man, directly or indirectly, of chemicals to the environment resulting in adverse impacts.

Contiguous Zone

A band of water extending from the outer edge of the territorial waters (which are usually 12 NM from the coast) up to 24 NM from the coast, within which a state can exert limited control for the purpose of preventing or punishing infringements of its customs, fiscal, immigration or sanitary laws and regulations.

Construction and Pre-comissioning Phases

2013 to end of 2018 – this phase will involve construction activities including an operational ramp-up period from late 2015 to late 2018.

Construction Corridor

During construction phase, corridor which encompasses all four pipelines.

Continental Shelf

A shallow submarine plain of varying width forming a border to a continent and typically ending in a comparatively steep slope to the deep ocean floor.

Continental Slope

The comparatively steep slope from a continental shelf to the ocean floor.

Copepod

Any of a large subclass (Copepoda) of usually minute freshwater and marine crustaceans.

Corrosion

The eating away of metal by chemical or electrochemical action.

Corrosion inhibitors

Chemicals that reduce the rate of corrosion on metal.

Cnidarian

Radially symmetrical animals having saclike bodies with only one opening and tentacles with stinging structures. They occur in polyp and medusa forms and include anemones, corals, hydroids and jellyfish.

Critical Cultural Heritage

Critical cultural heritage consists of one or both of the following types of cultural
heritage: (i) the internationally recognised heritage of communities who use, or have used within living memory the cultural heritage for long-standing cultural purposes; or (ii) legally protected cultural heritage areas, including those proposed by host governments for such designation (IFC 2012 Performance Standard 8, para 13). To be considered critical, the cultural heritage must be internationally recognised prior to the proposal of the project (IFC 2012, Guidance Note 8, paragraph GN24).

**Ctenophore**

Any of a phylum (Ctenophora) of marine animals superficially resembling jellyfishes but having biradial symmetry and swimming by means of eight bands of transverse ciliated plates —called also comb jelly.

**Cultural Heritage**

The heritage that includes artefacts, monuments, groups of buildings and sites that have a diversity of values including symbolic, historic, artistic, aesthetic, ethnological or anthropological, religious, scientific and social significance (UNESCO 1972).

**IFC Performance Standard 8: Cultural Heritage** defines Cultural Heritage as ‘(i) tangible forms of cultural heritage, such as tangible moveable or immovable objects, property, sites, structures, or groups of structures, having archaeological (prehistoric), paleontological, historical, cultural, artistic, and religious values; (ii) unique natural features or tangible objects that embody cultural values, such as sacred groves, rocks, lakes, and waterfalls; and (iii) certain instances of intangible forms of culture that are proposed to be used for commercial purposes, such as cultural knowledge, innovations, and practices of communities embodying traditional lifestyles’ (IFC 2012, Performance Standard 8, paragraph 3).

**Cultural Landscape**

Landscapes which represent combined works of nature and by humans, and they express a long and intimate relationship between people and their natural environment (UNESCO 2007).

**Cultural Resources**

Movable or immovable cultural heritage objects, sites, structures, groups of structures, and natural features and landscapes that have archaeological, paleontological, historical, architectural, religious, spiritual, aesthetic, or other cultural significance. Physical cultural resources may be located in urban or rural settings, and may be above or below ground, or under water. Their cultural interest may be at the local, provincial or national level, or within the international community.

**Culturally Appropriate**

An engagement process that identifies a practical and appropriate approach for sharing information and comments / views / opinions that is compatible with local cultural norms and behaviour.

**Cumulative Impact**

The combination of multiple impacts from existing projects, the proposed project, and/or anticipated future projects that may result in significant adverse and/or beneficial impacts that would not be expected in case of a stand-alone project.

**Cuttings**

Fragments of rock and other material displaced during the drilling or boring process.
**Decommissioning Phase**
Planned shut-down of a building, equipment, plant, etc., from operation or usage. Commencing 2065.

**Demersal**
Demersal fish live and feed on or near the seabed. They can be contrasted with pelagic fish.

**Demography**
The statistical study of the characteristics of human populations.

**Design Control**
The prevention or minimisation of adverse impacts through the use of good practice design controls. Design controls are often defined prior to the detailed consideration of potential impacts and mitigation measures within the ESIA process.

**Dewatering**
The process of dewatering is to remove the test water from the pipeline, after hydrotesting. This is usually carried out using dewatering PIGs.

**Dewatering and Pre-commissioning Spread**
The space and equipment needed for the dewatering and pre-commissioning activities.

**Diatoms**
Planktonic algae possessing a siliceous cell called a frustule. Globally, diatoms are the most abundant group within the phytoplankton.

**Diffusion Tube Monitoring**
A type of air quality monitoring equipment that passively absorbs air quality indicators over a given time (i.e., does not pump air over the sample medium). It provides an average concentration for the period of measurement.

**Dinoflagellates**
A group of single celled organisms possessing a flagellum (whip like locomotory structure). Many are photosynthetic organisms and form a major component of marine phytoplankton.

**Direct Impacts**
Direct impacts result from a direct interaction between a project activity and the receiving environment (e.g. between a project activity that results in permanent or temporary land take or use and the owner and users of that land).

**Disadvantaged and/or Vulnerable Individuals and Groups**
Individuals or groups within the project area of influence who could experience adverse impacts from the proposed project more severely than others based on their vulnerable or disadvantaged status. This status may stem from an individual's or group's race, colour, sex, language, religion, political, or other opinion, national or social origin, property, birth or other status. In addition other factors should be considered such as gender, ethnicity, culture, sickness, physical or mental disability, poverty or economic disadvantage, and dependence on unique natural resources. [2]

**Disclosure**
Release of information into the public domain. For the purposes of this document, disclosure refers to the release of the project and EIA/ESIA information to affected and interested stakeholders.

---

Diurnal Vertical Migration
Pattern of vertical migration occurring on a daily basis, such as in some copepods and fish.

Draft nets
Single wall of netting attached to a floating head rope and a weighted ground rope, designed so that a bag is formed into which the catch is drafted or hauled. Normally used in rivers or river estuaries.

Dredging
Process of excavating materials (seabed sediments or rock) underwater.

Dry Natural Gas
Natural gas is called 'dry' when it has had most hydrocarbons removed and is therefore almost pure methane. It is also known as 'consumer grade' natural gas.

Dust
'Dust’ is generally regarded as particulate matter less than 75 µm.

Ecosystem
A biological community of interacting organisms and their physical environment.

Ecosystem Service
The benefits people obtain from ecosystems. Following the lead of the Millennium Ecosystem Assessment, ecosystem services are typically classified along functional lines into four broad categories:

i. Provisioning services: the products people obtain from ecosystems such as food and fibre, fuel in the form of peat, wood or non-woody biomass, or water from rivers, lakes and aquifers. Goods may be provided by heavily managed ecosystems, such as agricultural and aquacultural systems and plantation forests, or by natural or semi-natural ones, for example in the form of capture fisheries or the harvest of other wild foods;

ii. Regulating services: the benefits people obtain from the regulation of ecosystem processes including, for example, the regulation of climate, hazards, noise, water, soil and air quality, and pollination;

iii. Cultural services: the cultural, spiritual, and educational benefits people obtain from ecosystems through, for example, recreation and tourism, spiritual or religious upliftment, or cultural heritage; and

Supporting services: the natural processes that maintain the other services such as soil formation, nutrient and water cycling, or primary production.

Ecotones
A transitional area of vegetation between two different plant communities, such as forest and grassland. It has some of the characteristics of each bordering plant community.

Electromagnetism
Refers to the interactions between electrically charged particles and magnetic force fields. Weak electromagnetic fields are present naturally. The operation of electrical equipment generates locally stronger electromagnetic fields.

Eluvial
Soils formed by in-situ weathering processes (i.e. wind).

Emergency Preparedness and Response Plan
The Emergency Preparedness and Response Plan defines how South Stream Transport plans, prepares and manages incidents and emergencies.

**Emergency Response Plan**

Emergency Response Plans are required for each high risk emergency incident/scenario as identified by the Emergency Risk Analysis. Contractors who will be doing the work will be responsible for preparing Emergency Response Plans for their work activities, and specifically those events identified by the Emergency Threat Analysis.

**Emergency Shut Down Valve**

A valve designed to stop the flow of gas in the pipeline upon the detection of a dangerous event. This provides protection against possible harm to people, equipment or the environment.

**Emergency Threat Analysis**

Emergency Threat Analysis determines the risks posed by potential emergencies and the need for specific Emergency Response Plans and related procedures as a contingency for emergency events.

**Engagement**

A process that involves consultation and/or disclosure.

**Environmental/Social Aspect**

An element of an organisation or project's activities, products or services that can interact with the environment or a social receptor that affects or can affect the environment.

**Environmental/Social Impact**

Any change to the environment or social status, whether adverse or beneficial, wholly or partially resulting from an organisation's activities, products or services.

**Environmental and Social**

For the purposes of this ESIA, the term “Environmental and Social” refer to all environmental, socio-economic and cultural heritage factors of the Project.

**Environmental and Social Impact Assessment (ESIA) / Environmental Impact Assessment (EIA)**

Systematic review of the environmental or socio-economic changes a proposed project may have on its surrounding environment.

**Environmental and Social Management System**

A system established to plan, manage, document and monitor an organisation's activities and processes and resultant environmental and social impacts in accordance with requirements of ISO 14001:2004 and IFC Performance Standard 1.

**Equator Principles**

The Equator Principles (EPs) are a credit risk management framework for determining, assessing and managing environmental and social risk in project finance transactions. The EPs are designed to help financial institutions overcome the challenges of incorporating risks associated with biodiversity and ecosystem services into their lending decisions. [3]

**Epiphytes**

A plant that grows on another plant but is not parasitic, such as diatoms growing on seaweed.

---

3 Definition as per the EP website available from www.equator-principles.com
Espoo Convention

The Espoo (EIA) Convention sets out the obligations of Parties to assess the environmental impact of certain activities at an early stage of planning. It also lays down the general obligation of States to notify and consult each other on all major projects under consideration that are likely to have a significant adverse environmental impact across boundaries. The Convention was adopted in 1991 and entered into force on 10 September 1997. [4]

Eurostat

Detailed statistical website on the EU.

Eutrophication

Excessive nutrient enrichment of a body of water, often leading to detrimental ecological changes.

Exclusive Economic Zone

An exclusive economic zone (EEZ) is a seazone for which a state has special rights over the exploration and use of marine resources, including production of energy from water and wind. It stretches from the seaward edge of the state's territorial sea out to 200 nautical miles from its coast (or to a neighbouring EEZ).

Fault

A planar fracture or discontinuity in a volume of rock, across which there has been significant displacement of one side with respect to the other. Rapid movement of faults causes earthquakes.

Fauna

The animals of a particular region, habitat, or geological period.

Feasibility Study

An analysis and evaluation of a proposed project to determine if it is technically feasible, is feasible within the estimated cost, and will be profitable.

Fixed Gillnets

Either stretched between two or more stakes driven into the bottom within the tidal area along the coast to target coastal species or be weighted to the seabed with weights attached to the ground line (footrope) supported by floats on the upper line (headrope). Can be used to catch demersal or pelagic fish.

Flora

The plants of a particular region, habitat, or geological period.

Fluvial

Soils formed by rivers and streams.

Flysch

Sedimentary rocks formed in deep water marine conditions.

Footprint

The spatial impact/ impression on the seabed or land from a project.

Foreign Direct Investment

Foreign Direct Investment (FDI) is the direct investment into production or business in a country by a company located or based in another country.

Fossil Fuels

Hydrocarbon fuels found naturally within the top layer of the Earth’s crust following decomposition of buried dead organisms such as plants and animals over a period of millions of years.

4 Definition as per the UNECE website available from http://www.unece.org/env/eia/eia.html
**Front End Engineering Design (FEED)**

Engineering that is conducted after completion of Feasibility Study (also known as Conceptual Design).

**Frame-first Construction**

A term used to describe the procedure in which hulls were constructed by first erecting frames and then attaching the outer skin of planking to them.

**Frequency**

A measure of the cycles per second in sound pressure fluctuations or vibration in Hertz (Hz). Humans can typically hear sound in the range of approximately 20 Hz to 20 kHz.

**Fugitive Source Emissions**

Fugitive emissions are non-combustion related emissions, such as gas leaks from pressurised equipment.

**Gamma Radiation**

Electromagnetic radiation of short wavelength. Gamma radiation is present naturally due to solar and geological processes. Anthropogenic activities may cause increased gamma radiation.

**Gastropod**

A class of molluscs comprising slugs and snails, typically having a flattened muscular foot with a head bearing stalked eyes.

**Gauging**

Gauging is undertaken to detect geometric anomalies in pipelines such as obstructions, dents and ovalities (out-of-roundness) that may have occurred during construction activities. This requires passage of a gauging tool (typically an aluminium gauge plate) which is attached to a PIG and passed through the pipeline.

**G-20**

The G20 is a forum for international cooperation on the most important issues of the global economic and financial agenda. It brings together finance ministers and central bank governors from 19 countries: Argentina, Australia, Brazil, Canada, China, France, Germany, India, Indonesia, Italy, Japan, the Republic of Korea, Mexico, Russia, Saudi Arabia, South Africa, Turkey, the United Kingdom, the United States of America plus the European Union, which is represented by the President of the European Council and by Head of the European Central Bank.

**Geohazard**

Geological or geomorphological situation that represents, or has the potential to develop further into, a situation leading to damage or uncontrolled risk. It includes landslides, seismic faults and volcanic activities, among other situations.

**Geomorphology**

Refers to the study of the evolution and configuration of landforms and the processes which shape them.

**Global Warming**

Global warming is an average increase in the temperature of the atmosphere near the Earth’s surface and in the troposphere, which can contribute to changes in global climate patterns.

**Good International Industry Practice (GIIP)**

Good International Industry Practice is the exercise of professional skill, diligence, prudence and foresight that would reasonably be expected from skilled and experienced professionals engaged in the
same type of undertaking under the same or similar circumstances globally.\[5\]

**Greenhouse Gases (GHG)**

Atmospheric gases considered to contribute to the greenhouse effect by absorbing and emitting radiation. They include carbon dioxide (CO2), methane (CH4), nitrous oxide (NO2), and water vapour.

**Grievance**

Formal complaint by individuals, groups or organisations who feel they have been adversely affected by project-related activities.

**Grievance Mechanism (or Grievance Procedure)**

Process of recording and addressing grievances so that they can be tracked through to a resolution.

**Gross Domestic Product**

The monetary value of all the finished goods and services produced within a country's borders over a certain period of time, usually calculated on an annual basis.

**Gross Value Added**

The value of goods and services produced by an area, sector or producer minus the cost of the raw materials and other inputs used to produce them. Unlike GDP, GVA does not include taxes or subsidies on the goods and services. GVA is useful for comparing performance across different areas as it is often difficult to allocate taxes and subsidies sub-nationally.

**Groundwater**

Water within rock pore space below the water table.

---

**Grout**

A material that is used for filling voids and sealing joints.

**Habitat**

The natural home or environment of an animal, plant, or other organism.

**Halocline**

A vertical gradient in ocean salinity.

**Harmful Substances**

Harmful substances are natural or man-made substances that adversely effect the functioning capability of organisms. In relation to the Convention on the Protection of the Black Sea against pollution, harmful substances are those substances that are identified as marine pollutants in the International Maritime Dangerous Goods (IMDG) Code.

**Hazard**

The potential to cause harm, including ill health or injury; damage to property, plant, products or the environment; production losses or increased liabilities.

**Hazardous Substance**

Natural or man-made chemicals that adversely affect human health or ecological functions.

**Hellenistic**

Relating to postclassical Greek history and culture.

**Herpetofauna**

Term referring to both reptiles and amphibians.

**Holoplankton**

Holoplankton are organisms that are planktonic for their entire life cycle.

---

\[5\] Definition as per the IFC Policy & Performance Standards and Guidance Notes. Glossary of Terms. Available from www.IFC.org
Examples of holoplankton include diatoms, radiolarians, dinoflagellates, foraminifera, amphipods, krill, copepods, and salps.

**Hominin**

The group consisting of modern humans, extinct human species and all our immediate ancestors (including members of the genera Homo (e.g. Homo neanderthalensis, Homo erectus, Homo habilis), and various species of Australopithecus, Paranthropus and Ardipithecus).

**Hydrocarbon**

Organic chemical compounds of hydrogen and carbon atoms that form the basis of all petroleum products. They may exist as gases, liquids or solids, examples being methane, hexane and paraffin.

**Hydrogen carbonate (HCO3-)**

This is the bicarbonate ion, also referred to as the hydrogen carbonate ion.

**Hydraulic Conductivity**

A coefficient that relates the discharge through an aquifer to the hydraulic head gradient.

**Hydrotesting**

Process of checking the integrity of a pipeline by filling it with water under pressure and testing for any loss of pressure (e.g. from leaks).

**Hydroid/ Hydrozoa**

Class of the phylum Cnidaria, usually with small and plant-like colonies of polyps and small jellyfish generative stages. Colonies are attached to solid forms such as rocks, shells or plants. There are also some planktonic forms such as the floating colony of polyps known as the Portuguese men-of-war.

**Ichthyoplankton**

Term used to describe the fish egg and fish larvae component of the plankton.

**Impressed Current System**

Impressed current cathodic protection (ICCP) systems are installed to prevent corrosion of underground metal pipeline systems. Corrosion of underground metal pipelines is a normal, natural process that is the result of an electrochemical reaction in which current flows from areas where corrosion is occurring (anodic areas) to areas where it is not (cathodic areas). A cathodic protection system reverses the process. With an impressed current system, current is discharged from special anodes placed in the same electrolyte (soil) in which the pipelines to be protected are buried.

**Indirect Impacts**

Indirect impacts result from other activities that happen as a consequence of the project (e.g. project implementation promotes service industries in the region).

**Intangible Cultural Heritage**

The Convention for the Safeguarding of the Intangible Cultural Heritage defines the intangible cultural heritage as the practices, representations, expressions, as well as the knowledge and skills (including instruments, objects, artefacts, cultural spaces), that communities, groups and, in some cases, individuals recognise as part of their cultural heritage. It is sometimes called living cultural heritage, and is manifested inter alia in the following domains:

- Oral traditions and expressions, including language as a vehicle of the intangible cultural heritage;
- Performing arts;
• Social practices, rituals and festive events;
• Knowledge and practices concerning nature and the universe; and
• Traditional craftsmanship.

Interfluve
The region of higher land between two rivers that are in the same drainage system.

International Finance Corporation (IFC)
Organisation that is a member of the World Bank, and promotes sustainable private sector investment in developing countries. [6]

International Finance Corporation Performance Standards
The Performance Standards provide guidance on how to identify environmental and social risks and impacts, and are designed to help avoid, mitigate, and manage risks and impacts as a way of doing business in a sustainable way. There are eight Performance Standards that clients must meet throughout the life of an investment by IFC. [6]

International Union for Conservation of Nature (IUCN) Red List
The IUCN Red List of Threatened Species provides taxonomic, conservation status and distribution information on plants and animals that have been globally evaluated using the IUCN Red List Categories and Criteria. This system is designed to determine the relative risk of extinction, and the main purpose of the IUCN Red List is to catalogue and highlight those plants and animals that are facing a higher risk of global extinction (those listed as Critically Endangered, Endangered and Vulnerable). The Red List website is http://www.iucnredlist.org

Invertebrates
Any animal lacking a backbone, including all species not classified as vertebrates, such as an arthropod, mollusc, annelid, coelenterate, etc.

Juniper woodland/scrub
A relatively heterogeneous woodland community, dominated in the tree layer by juniper species, as well as pubescent oak and oriental hornbeam.

Kavkaz Winery
ZAO Agrifirm Caucasus.

Keystone species
A species that exerts a large, stabilizing influence throughout an ecological community, despite its relatively small numerical abundance.

Known Development
The Russkaya CS, the Clearing in the Woods "Lesnaya Polyana" development, the Residence of Utrish development and the Zapovedny (Reserved) development.

Krai
An administrative area or region within the Russian Federation.

Kurgan
Mound of earth and stones raised over a grave or graves in Eastern Europe and Central Asia (Russian: Курган).

Landfall
The point at which the pipeline comes ashore from the sea.

---

6 Definition as per the IFC website. Taken from www.IFC.org
Landfall Facility
The point at which an offshore pipeline reaches the mainland.

Landfall Section
Approximately 3.9 km of onshore pipelines, 2.5 km of which will be buried and 1.4 km of which will be housed in microtunnels. The exit point of the microtunnels will be approximately 400 m from the shoreline at a depth of 23 m. The permanent onshore landfall facilities (approximately 142 m wide) are also included within the landfall section.

Landscape
An area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors (Council of Europe, 2000).

Landscape Impact
Impact on the landscape as a resource in its own right.

Larva
Juvenile form of an animal, differing in shape and appearance from the adult. Larvae undergo metamorphosis before reaching the adult form. Larvae can form an important component of the plankton in marine systems.

Laydown Area
Areas used for storing construction materials and equipment.

Leachable
To remove soluble or other constituents from soil or waste by the action of a percolating liquid.

Likelihood
The probability that an activity or effect will occur.

Line sources
An emission source that has a linear (one-dimensional) geometry. The most prominent linear sources are road traffic and aircraft air emissions.

Littoral
Zone between the low and high water marks.

Local Community/ies
Communities that have the potential to be affected by the Project. For the purposes of this socio-economic assessment, certain communities (Gai Kodzor, Rassvet, Varvarovka, Sukko and Supsekh) are referred to as ‘Local Communities’. These communities were identified as potentially Project-Affected Communities (PACs) in the Scoping Report, together with the town of Anapa but which is not identified as a Local Community in this chapter.

Macroalgae
Large algae including seaweeds.

Macrophyte
A plant large enough to be seen by the naked eye. Includes both seaweeds and marine angiosperms such as sea grass.

Magnetometer
A survey instrument that measures fluctuations in the earth’s magnetic fields for the purpose of detecting ferrous material.

Magnitude of Impact
The degree and extent to which a project changes the environment.
**Mammal**
A class of warm-blooded vertebrates, Mammalia, having mammary glands in the female.

**Marginalised Groups**
Groups characterised by shared traits such as ethnicity, income levels, or disability that are not present or represented in the mainstream of social, economic or political life of a country. Thus, they may be disproportionately adversely affected by project impacts.

**Marshalling Yard**
Onshore support facilities. An area where materials and equipment are temporarily stored and location of managerial support for South Stream Transport and its contractors. Located at the Russian ports Temyruk and Novorossiysk. For the purposes of this document, marshalling yards are areas within ports.

**Maximum Permissible Concentration**
An amount, usually a combination of time and concentration, beyond which any exposure of humans to a chemical or physical agent in their immediate environment is unsafe. For the purpose of this report, these are average limits set by the authorities of the Russian Federation.

**Maximum Permissible Level**
The concentration of a harmful substance within soil or water below which there are no direct or indirect adverse impacts upon human health (where exposure is continuous over a lifetime).

**Meroplankton**
Meroplankton are organisms that are planktomic for only a part of their life cycles, usually the larval stage. Examples of meroplankton include the larvae of echinoderms (such as sea urchins and sea stars), crustaceans, marine worms, some marine gastropods and most fish.

**Mesophilic meadow**
These are grassland and herb communities which are located on a river floodplain. They comprise vegetation communities typical of moist and more nutrient rich environments.

**Mesophilic woodland**
These woodlands occur in the riverine floodplains and valleys and are dominated by woody species and a diverse woodland ground-flora.

**Metoecean**
Abbreviation of the words ‘meteorology’ and ‘oceanography’.

**Meteorological Conditions**
The prevailing environmental conditions that include wind, precipitation and sunlight.

**Meteorology**
Refers to the study of weather.

**Microtunneling**
Microtunneling is a trenchless construction method used to excavate underground tunnels. Microtunneling is defined as a remotely-controlled, guided, ground-boring and pipe-jacking operation that provides continuous support to the excavation face by applying mechanical or fluid pressure to balance groundwater and earth pressures.

**Migration**
Any regular animal journeys along well-defined routes, particularly those involving a return to breeding grounds.
**Millennium Ecosystem Assessment**

The Millennium Ecosystem Assessment (MA), a collaboration of over 1,360 experts, was published in 2005 and provided the first state-of-the-art scientific appraisal of the condition and trends in the world’s ecosystems and the services they provide and the options to restore, conserve or enhance their sustainable use.

**Million tonnes of oil equivalent (mtoe)**

A unit of energy representative of the amount of energy released by combustion of one million tonnes of crude oil. Conversion of mtoe to bcm were calculated using a factor of 1 bcm=0.89 mtoe

**Mitigation Measures**

Management measures put forward to prevent, reduce and where possible, offset any adverse environmental or socio-economic impacts. For the purposes of this document, these measures also include enhancement strategies aimed at increasing beneficial impacts.

**Mobile Source Emissions**

Exhaust from motor vehicles, airplanes, locomotives, and other engines and equipment that can be moved from one location to another.

**Monument**

Architectural works, works of monumental sculpture and painting, including cave dwellings and inscriptions, and elements, groups of elements or structures of special value from the point of view of archaeology, history, art or science (UNESCO 1972).

**Multi-beam Echo Sounder**

A survey instrument that emits multiple acoustic beams of sound waves to determine sea floor depths over a wide area for the purpose of creating bathymetric maps.

**Mutagenic**

A physical or chemical agent that changes the genetic material, usually DNA, of an organism.

**Nauplii**

The first larval stage of many crustaceans, having an unsegmented body and three pairs of appendages.

**Nearshore Section**

Four buried pipelines extending from the exit point of the microtunnels, located approximately 400 m from the coast at a water depth of approximately 23 m, and extends approximately 425 m out to a water depth of 30 m.

**Neolithic**

The Neolithic culture (c. 7000-2000 BC) developed animal husbandry and agricultural cultivation, alongside hunting wild animals, fishing and gathering wild foods.

**Nitrogen dioxide (NO₂)**

Nitrogen dioxide is one of several nitrogen oxides and is emitted by (and forms from emissions of) cars, trucks and buses, power plants, and off-road equipment. In addition to contributing to the formation of ground-level ozone, and fine particle pollution, NO₂ is linked with a number of adverse effects on the respiratory system.

**Nitric oxide (NO)**

A colourless, poisonous gas, produced as an intermediate during the manufacture of nitric acid from ammonia or atmospheric nitrogen.

**Nitrogen oxides (NOₓ)**

Also known as oxides of nitrogen. A group of gases emitted from fossil fuel
combustion that predominantly comprises nitric oxide, nitrogen dioxide, nitrous acid and nitric acid.

**Noise**
Unwanted sound.

**Non-destructive Testing (NDT)**
Methods of inspecting and testing the quality or integrity of infrastructure or equipment which do not involve the removal or testing to destruction of representative sections.

**Non-methane Volatile Organic Compounds (NMVOC)**
See Volatile Organic Compounds. NMVOC excludes methane from this group of chemicals.

**Octave Band Centre Frequency**
Used within acoustics to define the centre frequency of each octave where successive higher frequencies are represented by a doubling of the frequency.

**OECD Common Approaches**
The mission of the Organisation for Economic Co-operation and Development (OECD) is to promote policies that will improve the economic and social well-being of people around the world. The OECD provides a forum in which governments can work together to share experiences and seek solutions to common problems. The OECD Common Approaches are Recommendations of the Council on Common Approaches for Officially Supported Export Credits and Environmental and Social Due Diligence adopted by the OECD Council on 28 June 2012. [7]

---

7 Definition as per the OECD website. Taken from www.oecd.org

**Offshore Section**
Four pipelines each approximately 225 km in length laid directly on the sea bed from the maximum water depth where dredging works will take place (30 m) to the boundary between the Russian and Turkish EEZs.

**Oil Spill Prevention and Response Plan**
All contractors and operators of vessels working on behalf of South Stream Transport will be required to developing and implementing an Oil Spill Prevention and Response Plan which will define actions to be taken to minimise the risks of marine oil spillages, as well as the actions to be undertaken following a spillage.

**Oligochaete**
Any of various annelid worms of the class Oligochaeta, including the earthworms and a few small freshwater forms.

**Operational Phase**
Phase commencing at the end of construction and pre-commissioning phase (end of 2018) and ending 2065. The Project will have an operational design life of 50 years.

**Orogeny**
Period of mountain building due to the movement of tectonic plates in the Earth’s crust.

**Oxides of nitrogen (NOₓ)**
See nitrogen oxides.

**Ozone (O₃)**
An unstable, poisonous allotrope of oxygen that is formed naturally in the ozone layer from atmospheric oxygen and also emitted at ground level during combustion of fossil fuels. It is a highly reactive oxidizing agent.
used to deodorize air, purify water, and treat industrial wastes.

**Particulates or Particulate Matter**

Matter in the form of minute separate solid or liquid particles.

**Particulate matter (PM$_{2.5}$)**

Particulate matter less than 2.5 micrometres in diameter (PM$_{2.5}$) are called ‘fine’ particles. These particles can only be detected with an electron microscope. Sources of fine particles include all types of combustion, including motor vehicles, power plants, residential wood burning and some industrial processes.

**Particulate matter (PM$_{10}$)**

Particulate matter less than 10 micrometres (or ‘microns’) in diameter. They are small enough to penetrate deep into the lungs, potentially causing serious health problems. This is mainly due to the combustion of fossil fuels (construction dust for example is generally more coarse).

**Party/Parties of Origin**

A country involved in a transnational linear project where an activity is planned to be undertaken, which may affect an Affected Party. See Affected Party above.

**Pelagic**

Freely swimming in the upper water column.

**Pelite**

Clay

**Permanent Halocline Layer**

Layer of maximal salinity gradient in the water column.

**Permanent Right of Way**

During Operational Phase, approximately 95 m wide and 2.5 km long along the landfall section pipelines.

**Permanganate oxygen demand**

Permanganate is a strong oxidising agent. Permanganate oxygen demand gives an indirect indication of the amount of organic matter or reduced species (typically those containing Fe or Mn) present in groundwater; the higher this value the higher the demand for permanganate and therefore the higher the content of organic/reduced species.

**Picoplankton**

The smallest component of the plankton, ranging from to 0.2 to 2 µm in size, predominantly comprising bacteria but with some other organisms.

**Pipelaying Vessel**

A vessel designed for welding together pipelines and laying them on the seabed.

**Photic zone**

The depth zone of the water column in the sea or other water body that is exposed to sufficient sunlight for photosynthesis to occur. Also known as the ‘euphotic’ zone the depth of which depends on the clarity of the water and consequent light penetration.

**Phytoflagellates**

All photosynthetic flagellates, including dinoflagellates, some planktonic green algae and others.

**Phytoplankton**

The plant component of the plankton comprising a variety of organisms. The most common components of marine
phytoplankton are the diatoms and dinoflagellates.

**Pipeline Construction**

The construction phase of the pipeline development.

**Pipeline Inspection Gauge (PIG)**

A bullet shaped, cylindrical or spherical capsule which is inserted into a pipeline and travels along with the fluid in the pipeline. PIGs have a variety of purposes during precommissioning, commissioning and operations, including scraping the pipeline clean from rust, wax or other deposits. More sophisticated PIGs, called intelligent PIGs, carry instrumentation used in pipeline inspection.

**Pigging**

Pigging is passing a solid plug (PIG) through a pipeline. See above.

**Pig Trap Facility**

Pig traps are used for inserting PIGs into a pipeline then launching, receiving, and finally removing them without flow interruption.

**Pipe Jacking**

Pipe jacking is a technique for installing underground pipelines, ducts and culverts. Powerful hydraulic jacks are used to push specially designed concrete pipes through the ground behind a shield or tunnel boring machine at the same time as excavation is taking place. The method provides a flexible, structural, watertight, finished conduit as the tunnel is excavated.

**Piscivorous**

Habitually feeding on fish; fish-eating

**Planktivore**

An animal that feeds primarily on plankton

**Plankton**

Minute plants (phytoplankton) and animals (zooplankton) that drift in the surface waters of seas and lakes.

**Polis**

Ancient Greek city-state (Greek: πόλις).

**Pollution**

The introduction by man, directly or indirectly, of substances or energy to the environment resulting in deleterious effects such as harm to living resources.

**Polychaete**

An important group of segmented marine worms that can be either free-living or tube-dwelling. A major component of the benthos in many areas, polychaete tubes may also form biogenic reefs.

**Polypropylene**

A thermoplastic polymer used in a wide variety of applications.

**Pound nets**

Net walls, anchored or fixed on stakes, reaching from the bottom to the surface. Nets are opened at the surface and include various types of fish herding and retaining devices. Normally used to target migrating, pelagic species.

**Pottery sherds**

The individual pieces of broken ceramic vessels.

**Pre-commissioning**

Pre-commissioning is the process of proving the ability of a pipeline and piping systems to meet operational requirements prior to putting the pipeline into service.
Prehistoric
The time before recorded history and writing. Includes the Palaeolithic, Epipalaeolithic, Neolithic, Copper Age/Chalcolithic/Eneolithic, Bronze Age and Iron Age periods.

Preservation in place / in situ
The preferred sectoral good practice method of treating cultural heritage remains. Where feasible and appropriate, this involves preserving sites in place (in situ). Sites will often be given additional protection and safeguard measures such as flagging, fencing, covering, and signage.

Primary Producer
Organism that is able to synthesize organic material (usually sugar) from less complex compounds such as carbon dioxide. Photosynthesis is the fundamental process of in primary production so most primary producers are plants. Primary production also occurs by a process called chemosynthesis, using chemicals instead of light.

Priority ecosystem services
IFC Performance Standard 6 (para. 24) defines priority ecosystem services as:

i. Those services on which project operations are most likely to have an impact and, therefore, which result in adverse impacts to Affected Communities; and/or

ii. Those services on which the project is directly dependent for its operations (e.g., water).

The Performance Standards also state that "when Affected Communities are likely to be impacted, they should participate in the determination of priority ecosystem services in accordance with the stakeholder engagement process as defined in Performance Standard 1”.

In order to identify priority services in a transparent and systematic manner which supports participation of Affected Communities, priority services are identified in this assessment as those services for which the impacts are assessed to be of moderate or high significance.

The Project
South Stream Offshore Pipeline – Russian Sector.

Project Affected Community
Communities that are affected by the activities of a project. For the purposes of this document, PACs are defined as communities that lie (at least in part) within 2 km of the landfall section of the Project, and within a 300 m zone either side of potential (existing) access roads.

Project Area
Refers to the Landfall, Nearshore and Offshore Sections (not the access roads or marshalling yards which are considered the 'Project').

Project Area of Influence
Where the project involves specifically identified physical elements, aspects, and facilities that are likely to generate impacts, environmental and social risks and impacts will be identified in the context of the project’s area of influence

Project Leaflet
Brief publication containing information about a project which is made available to stakeholders.

Project Proponent
The developer, or sponsor, of a project. For the Project, this is South Stream Transport.
**Project Zone of Influence**

The geographical area within which views of the construction and operational phases of the Project and the marshalling yards could potentially be possible, including views of vehicles and vessels on the land and sea delivery routes.

**Proyekt**

The Proyekt is the Russian project design documentation submitted to the Russian Authorities for review. The Final EIA Report is incorporated under Chapter 7 of the Proyekt and submitted to the relevant Russian Federation authorities for review and approval.

**Proposed Development**

Development detailed in the GDP.

**Pycnocline**

The layer in which the density gradient is greatest within a body of water.

**Public Disclosure**

Disclosure of project or ESIA–related information to stakeholders for review and as an input to consultations.

**Public Hearing**

Often, but not always, refers to a public meeting that must be announced, organised and reported upon according to national regulatory requirements. See ‘Public meeting’.

**Public Meeting**

Open meeting which may be attended by any member of the public. Need not be a meeting required under specific legislation.

**Purse seine**

A long net, which falls as a curtain from a floating head rope, used to surround shoals of fish. After encirclement, the bottom rope is pulled tight to trap the fish in the ‘purse’.

**Radionuclide**

An atom with an unstable nucleus that decays with the release of radiation. Radionuclides occur naturally or can be produced artificially. Also known as radioisotopes.

**Ramp-up**

For the purposes of this document, ramp up refers to an increase in the amount of gas being transported through the pipeline(s).

The period after completion of construction of a project during which production begins to increase towards operational / design capacity. In terms of this Project, ramp-up refers to the gradual increase in gas transport rates until operational capacity is met.

**Ratified**

When a state makes a final approval and formal expression of its consent; for example, to be bound by a treaty or convention. This usually occurs after signature.

**Receptor**

The aspect of the environment (air, water, ecosystem, human, fauna, etc.) that is affected by/interacts with an environmental or socio-economic impact.

**Recycling/Recovery**

The conversion of wastes into usable materials and/or extraction of energy or materials from wastes.

**Red List / Red Book**

For the purposes of this document, this refers the IUCN Red list (see definition below), the National Russian Red Data Book, the regional Krasnodar Red Data...
Book or the Black Sea Red Data Book. These books contain animal and plant species that are considered of ‘critical’ importance under categories such as extinct, endangered and vulnerable. They also list species that are of lower importance under headings such as rare or lower risk. Species are also categorised under data deficient or not evaluated.

Reinstatement Work

The process of returning the landscape affected by the construction of a development back to its previous state.

Remotely Operated Vehicle/ Remotely Operated Towed Vehicle

Remotely Operated Vehicle (ROV) and Remotely Operated Towed Vehicle (ROTV), both of which are used for underwater surveys, are submarine survey robots controlled and powered from the surface by an operator/pilot via an umbilical link.

Reprotoxic

Having a toxic effect on the process of reproduction.

Residual Impacts

Residual impacts are impacts that remain after mitigation measures, including those incorporated into the project’s Base Case design and those developed in addition to the Base Case design, have been applied.

Reuse

To use a material or product again after it has been used. Reuse may be for the same function or a new function.

Risk

The probability that a specified event will occur and the severity of the consequences of the event.

Routine Activity

An activity that occurs during routine operations when plant, vessels or equipment is operating as specified within the design base case.

Sacrificial Anode

A metal (usually zinc, aluminium or magnesium) that is placed on offshore steel pipelines to corrode and prevent corrosion of the pipeline by providing cathodic protection (exchange of electrons) of its steel surface.

Salinity

Total amount of salt dissolved in aqueous solution. Salinity is measured in parts per thousand.

Sanitary Protection Zones

A buffer zone between a construction or operating site and nearby residential areas. It is established for industrial facilities that emit pollutants into the atmosphere or have other environmental impacts.

Sapropel

Marine sediment rich in organic matter.

Scoping

Early stage in the ESIA process that appraises the likely key issues requiring detailed assessment. A scoping process (in relation to IFC PS1) is the establishment and maintenance of a process for identifying the initial environmental and social risks and impacts of a project. The aspects of the project (i.e., type, scale and location) along with available baseline data is used to guide the scope and level of effort devoted to the risk and impacts identification in the ESIA. The scoping process is to be consistent with Good International Industry Practice (GIIP) and will determine the appropriate / relevant
methods and assessment procedures. The process also involves a mechanism for the collection of comments made by different stakeholders. [8]

**Screening**

The process by which a decision is taken on whether or not EIA is required for a particular Project.

**Seagrass**

The only angiosperms that are adapted to living submerged in the sea. They superficially resemble terrestrial grasses and may form extensive submarine “meadows”.

**Seascape**

Landscapes with views of the coast or seas, and coasts and the adjacent marine environment.

**Seaweed**

Often called macroalgae, large algae often growing attached to rocks or other solid objects, living below the high-water mark.

**Secondary Data**

Data collected by someone other than the user.

**Sediment**

Sediment is any particular matter that is broken down by processes of weathering and erosion, and is subsequently transported by the action of wind, water, or ice, and/or by the force of gravity acting on the particle itself.

**Sensitive Receptor**

Locations where people that could potentially be impacted by the Project, e.g., hospitals, nursing homes, schools, residential housing.

**Sensitivity**

The recovery rate of the receptor from significant disturbance or degradation.

**Sensitivity (of ecological resource)**

The recovery rate of flora or fauna from significant disturbance or degradation. Greater levels of sensitivity result in an ecological resource that can more easily be affected or harmed.

**Seismicity**

The frequency, intensity and distribution of earthquakes in a specific area.

**Setting (cultural heritage)**

The setting of a heritage structure, site or area is defined as the immediate and extended environment that is part of, or contributes to, its significance and distinctive character. Beyond the physical and visual aspects, the setting includes interaction with the natural environment; past or present social or spiritual practices, customs, traditional knowledge, use or activities and other forms of intangible cultural heritage aspects that created and form the space as well as the current and dynamic cultural, social and economic context (ICOMOS 2005 X’ian Declaration on the Conservation of the Setting of heritage structures, sites and areas).

**Shell-first Construction**

A term used to describe the process by which all or part of the outer hull planking was erected before frames were attached to it.

---

8 Definition as per the IFC website. Taken from www.IFC.org
Shiblyak
These woodlands are diverse in structure, floristically rich and are dominated by woody species including pubescent oak, oriental hornbeam, and juniper.

Sideboom
A track-type or wheel-type tractor having a boom mounted on the side of the tractor, used for lifting, lowering, or transporting.

Side-scan Sonar
A survey instrument which emits acoustic beams (sound waves) laterally to capture an image of the sea floor for the purpose of locating objects and obstructions.

Signed
When a State expresses its consent to be bound by a treaty.

Site Preparation
The preparation of a site prior to construction of a development, for example levelling of a site to enable access or parking.

Slurry
A suspension of small size solid particles and water. For the purpose of this report this refers to a mix of rock / soil, bentonite and water produced during the excavation of tunnels using a Tunnel Boring Machine.

Soil
A material comprised of a mixture of mineral and organic materials that usually has the ability to support rooted plants in a natural environment.

Source Protection Zone
Equivalent to sanitary zones as defined by the Ministry of Health, Moscow 2002. SanPin 2.1.4.1110-02.

South Stream Bulgaria AD (SSB)
South Stream Bulgaria AD is a Joint Project Company (JPC) of two major energy companies responsible for the development. The two JPCs are Russian company OAO Gazprom (50% stake) and Bulgarian company Bulgarian Energy Holding EAD (50% stake).

South Stream Offshore Pipeline
The overall South Stream Offshore Pipeline covering all three countries (Russia, Turkey and Bulgaria).

South Stream Transport
Previously, the Project was developed by Gazprom during 2009-2011, and then by South Stream Transport AG during 2011-2012. South Stream Transport then moved head office from Switzerland to the Netherlands and established South Stream Transport B.V., in November 2012.

Spill Prevention and Response Plan
Plan which will be developed and maintained by each Project contractor defining the measures to be taken to minimise the risk of onshore oil spillages and the responses to be taken in the event of a spillage.

Stakeholder
Any individual, group or organisation potentially affected by a project, or which has an interest in, or influence over, a project.

Stakeholder Database
Mechanism for recording stakeholders’ comments and concerns, and managing the stakeholder engagement process.
Stakeholder Engagement

As stated by IFC in PS 01 “Stakeholder engagement is the basis for building strong, constructive, and responsive relationships that are essential for the successful management of a project's environmental and social impacts.” Thus, it is an activity covering different types of interactions with stakeholders over the life of a project. Can include, but is not limited to disclosure and consultation during preparation of an ESIA Report.

Stakeholder Engagement Plan

A Stakeholder Engagement Plan (SEP) forms part of the ESIA documentation and is intended to provide a plan and implementation strategy to guide stakeholder engagement throughout the project lifecycle.

Stakeholder Identification

A process of identifying individuals or groups likely to be affected by the project both directly and indirectly, and/or who may have an interest in the project or influence over the project.

Stakeholder Mapping

Process of identifying and evaluating stakeholders based on their characteristics and connections to a project, and prioritising them to identify the appropriate type of engagement.

Steppe

A large, flat plain with dominated by grasses and with very few trees.

Steppefied Secondary Meadow

These are meadow areas dominated by grasses and herbaceous species that were previously agricultural land (former vineyards, orchards, fields), which are now derelict.

Stinger

A long heavy horizontal structural piece of framework used as a support for the pipeline during offshore pipelaying.

Stratification

A layered configuration of materials. Often used in the context of sediment stratification that describes the vertical changes in sediment characteristics in an active sedimentary basin, like the Black Sea, or in a rock formation.

Stray Finds

Isolated finds of single archaeological artefacts, often portable objects, which do not form part of a wider archaeological site.

Study Area

The mapped geographical area in which potential impacts are predicted (as determined through scoping) and therefore warrants investigation during the ESIA process. This is different for each biophysical and social environmental aspect.

Sub-bottom Profiler

A survey instrument which emits low frequency pulsed acoustic energy (sound waves) used to image sediments and objects buried beneath the sea floor.

Sulphur Dioxide (SO₂)

A toxic gas that can be released by fossil fuel combustion such as industrial processes and road traffic and which is proportional to the sulphur content in the fuel.

Supralittoral

Also known as the splash zone. The area above the spring high tide line that is regularly wetted but not submerged by water.
Surface Water
Ponded water on the surface of the land predominantly in the form of rivers, streams and lakes.

Swale
A man-made swale is a low tract of land or drain that is designed to manage water runoff, filter pollutants, and increase rainwater infiltration. Swales, by slowing and capturing water runoff and by spreading it horizontally across the landscape, facilitate runoff infiltration into the soil.

Taxon
Plural-Taxa. A group of organisms of any taxonomic rank.

Territorial Waters
A belt of coastal waters extending at most 12 nautical miles from the baseline (low water mark) of a coastal state.

Thermocline
Generally a gradient of temperature change, but applied more particularly to the zone of rapid temperature change between the warm surface waters and cooler deep waters in a thermally stratified water column.

Tommilyar
This habitat type is comprised of herbaceous plant communities with a prevalence of species associated with dry, hot environments.

Total Particulate Matter
All particulate matter is the term for solid or liquid particles found in the air.

Town of Anapa
The urbanised area of the town of Anapa, one of many communities within the Anapa Resort Town municipal district.

Toxicity
Inherent potential or capacity of a substance to cause adverse effects on living organisms.

Trailing Suction Hopper Dredger
A ship that removes sediment from the seabed. A trailing suction hopper dredger (TSHD) trails its suction pipe when working, and loads the dredged material into one or more compartments (hoppers) in the vessel.

Transboundary
Crossing a provincial, territorial or national boundary or border.

Transboundary Impact
An impact which crosses any boundaries between two geopolitical boundaries (i.e. a border).

Transnational Linear Projects
Linear projects that span multiple countries.

Trenching
Process by which excavation or dredging equipment is used to excavate a trench.

Trip Generation
An estimate of how much traffic a project will create, known as trip generation analysis.

Trophic
Of or involving the feeding habits or food relationship of different organisms in a food chain.
Turbid
Water containing suspended particles or sediment.

Turbidite
Sediments which are transported and deposited by density flows known as turbidity currents, which are similar to underwater avalanches.

Turbidity (of water)
Water that is cloudy or hazy as a result of a density difference created by dispersed sediment within the body of the water. It is used as a test of water quality.

Tunnel Boring Machine
Tunnel boring machine (TBM) is the tool used to bore through the ground to create a tunnel – it is a remotely operated steel cylinder with a rotating cutting head.

Vibration Acceleration
A measurement of the ground borne acceleration caused by vibration, usually weighted to consider the frequency dependant human response to vibration of different frequencies.

Vibration Velocity
A measurement of the ground borne velocity of the ground caused by vibration, usually weighted to consider the frequency dependant human response to vibration of different frequencies.

Viniculture
The cultivation of grapevines for winemaking.

Visual Amenity
The overall pleasantness of the views enjoyed by people of their surroundings.

Visual Impact
Impact on specific views and on the general visual amenity experienced by people.

Volatile Organic Compounds
A group of chemicals (methane is excluded) that contain the element carbon in their molecular structure (i.e., are ‘organic’). They easily vaporise at room temperature and most of them have no colour or smell.

Vulnerable (or disadvantaged)
Term used to describe individuals and groups who may be directly and differentially or disproportionately affected by a project because of their disadvantaged or vulnerable status. This status may stem from an individual's or group's race, colour, sex, language, religion, political or other opinion, national or social origin, property, birth, or other status. Other factors that may contribute to such a status are gender, age, ethnicity, culture, literacy, sickness, physical or mental disability, poverty or economic disadvantage, and dependence on unique natural resources.

Water Table
The water level in an unconfined aquifer at which the pressure head is equal to atmospheric pressure.

Wastewater
Water contaminated with sanitary, commercial, industrial, agricultural or surface runoff wastes.

Waste management facility
An installation which receives waste and either: transfers waste to another destination for processing; prepares the waste for reuse or recycling; carries out a recycling or recovery process; or permanently disposes of the waste.
Wellbeing

The IFC Performance Standards do not provide a definition of well-being although they do make reference to the MA in the context of well-being which defines the term as follows:

"Human well-being is assumed to have multiple constituents, including the basic material for a good life, such as secure and adequate livelihoods, enough food at all times, shelter, clothing, and access to goods; health, including feeling well and having a healthy physical environment, such as clean air and access to clean water; good social relations, including social cohesion, mutual respect, and the ability to help others and provide for children; security, including secure access to natural and other resources, personal safety, and security from natural and human-made disasters; and freedom of choice and action, including the opportunity to achieve what an individual values doing and being. Freedom of choice and action is influenced by other constituents of well-being (as well as by other factors, notably education) and is also a precondition for achieving other components of well-being, particularly with respect to equity and fairness."

Zone of Theoretical Visibility (ZTV)

The zone of theoretical visibility. The geographical area within which the landscape and/or seascape where the Project is theoretically visible.

Zoëa

A stage in the larval development of certain decapod crustaceans, particularly crabs.

Zone of Influence

The geographical area and the ecological features within it which have the potential to be impacted by the Project.

Zoophytes

A plant-like animal, esp. a coral, sea anemone, sponge, or sea lily.

Zooplankton

The animal component of the plankton, including holoplankton (animals that are permanently planktonic) and meroplankton (larval and juvenile stages of non-planktonic animals).

1 Introduction

1.1 South Stream Offshore Pipeline Overview

The South Stream Offshore Pipeline is the offshore component of the South Stream Pipeline System that will transport natural gas extracted in Russia to countries of Central and South-Eastern Europe (Figure 1.1).

This Environmental and Social Impact Assessment (ESIA) Report has been prepared specifically for the Russian Sector of the South Stream Offshore Pipeline, referred to as the ‘South Stream Offshore Pipeline – Russian Sector’ or as ‘the Project’ throughout this Report1.

Separate ESIA Reports have been prepared by South Stream Transport B.V. (South Stream Transport) for the Turkish and Bulgarian Sectors of the South Stream Offshore Pipeline. In addition, separate Environmental Impact Assessments (EIAs) have been undertaken by other companies for the other components of the South Stream Pipeline System.

Figure 1.1 South Stream Pipeline System

---

1 Where this report refers to the ‘South Stream Offshore Pipeline’, and not to ‘the Project’, the intent is to refer to the overall South Stream Offshore Pipeline covering all three countries (Russia, Turkey and Bulgaria).
The South Stream Offshore Pipeline will comprise four adjacent pipelines extending approximately 931 kilometres (km) across the Black Sea from the Russian coast near Anapa, through the Russian, Turkish, and Bulgarian Exclusive Economic Zones (EEZs), to the Bulgarian coast near Varna (Figure 1.2). In addition to the offshore pipelines, the South Stream Offshore Pipeline will consist of short onshore sections in Russia and Bulgaria, with facilities to meter the gas prior to and after transportation through the offshore system. When complete, the South Stream Offshore Pipeline will be able to transport 63 billion cubic metres (bcm) of natural gas annually. Each of the four pipelines will have a maximum flow rate of approximately 15.75 bcm per year, and a maximum design pressure of 300 bar.

**Figure 1.2 South Stream Offshore Pipeline**

All geographic boundaries depicted in maps in this ESIA Report relate to February 2014.

This chapter provides an overview of the proposed development in Russia, the impact assessment process, the scope of the ESIA Report, the anticipated schedule for development, and the structure and content of this ESIA Report.

### 1.1.1 Need for the South Stream Offshore Pipeline

#### 1.1.1.1 Current European Union Gas Consumption, Demand, and Pipeline Capacity

Natural gas plays a significant role in Europe’s energy mix: in 2011 approximately 24% (Ref. 1.1) of the European Union (EU) member states’ (EU-28) primary energy consumption
came from natural gas, with only around 41% of that demand being met by domestic EU-28 production (i.e. by gas fields within the EU).

In 2011, EU gross inland consumption (production plus net import) of dry natural gas was approximately 492 bcm (Ref. 1.2), production was approximately 185 bcm (Ref. 1.3), and net imports amounted to approximately 308 bcm (Ref. 1.4).

The EU secures imports from a variety of sources, including traditional suppliers such as Russia, Norway and Algeria (Ref. 1.5). Within the broader European region (i.e. not limited to the 28 EU member states), Russia supplied approximately 130 bcm in 2012 (Ref. 1.6).

1.1.1.2 European Union Production and Demand Forecasts

Future estimates of EU production and demand are inherently uncertain and require a number of assumptions regarding, for example, changes in gross domestic product (GDP), population, energy sector composition and prices, and government policy. Given these uncertainties, this section incorporates forecasts from two sources: International Energy Agency (IEA) (Ref. 1.1 to 1.5), which is an independent agency that produces yearly reports on the World energy and production and consumption and Wood Mackenzie (WM) (Ref. 1.7), an energy consulting company engaged by South Stream Transport as Lenders’ Gas Market Consultant to carry out a market analysis with specific reference to the South Stream Offshore Pipeline. Each source analyses three scenarios designed to reflect future demand relative to supply. The following sections present the results from each of these reports.

The results from the IEA and WM reports are not directly comparable because they are based on different future demand scenarios and geographical scope. The IEA report bases its forecasts on a definition of Europe that is reflected by the 28 members of the European Union, whereas the WM report defines Europe as the 28 member states as well as Bosnia and Herzegovina, Norway, Serbia, Switzerland and Turkey. It should be noted that the inclusion of, particularly, Norway (production) and Turkey (demand) is a key source of the differences in the forecasts.

International Energy Agency (IEA) Forecasts

Table 1.1 describes the IEA scenarios for future EU demand and the assumptions that underpin them.

---

2 The WM data presented in this report reflects the forecast conventional natural gas supply for the following countries: Austria, Bulgaria, Croatia, Czech Republic, Denmark, France, Germany, Hungary, Ireland, Italy, Norway, Netherlands, Poland, Romania, Serbia, Slovakia, Spain, Turkey, and United Kingdom. Forecast demand for conventional gas is presented for the following countries: Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Macedonia, Netherlands, Norway, Portugal, Romania, Serbia, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey, and United Kingdom.

Converted from mtoe to bcm using conversion factor of 1.11

In contrast to increasing demand, EU natural gas production is forecast by IEA to fall from 185 bcm per year in 2011 to 104 bcm per year in 2035 (Ref. 1.1). Reduced domestic gas production means that under the New Policy Scenario approximately 79% of EU forecast demand in 2035, or 401 bcm per year in absolute terms, will have to be met by natural gas imports (Ref. 1.1). Table 1.3 shows the predicted net import requirements for all future scenarios, given forecast demand.

Wood Mackenzie (WM) Forecasts

Table 1.4 describes the WM scenarios for future EU demand and the assumptions that underpin them.
Table 1.4 WM: Future Demand Scenarios for Europe

<table>
<thead>
<tr>
<th>Scenario Assumptions</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Base case</strong></td>
<td>Demand growth will be driven by increasing energy intensity in emerging European economies as well as recovery in the power sector. Gas demand in the power sector will recover somewhat gas utilisation from the current record low levels. This will be supported by a fundamental rebalancing of the EU Emission Trading Scheme taking effect towards the end of the forecast period, against a backdrop of coal retirements. In mature markets such as Italy, Germany and the UK gas demand will remain flat or decline slightly. Gas markets in Central and Eastern Europe, including Turkey, have greater long term scope for gas penetration driven by gas infrastructure developments and increasing energy demand per capita. Under the Base Case scenario, gas demand is estimated to be 623 bcm by 2035.</td>
</tr>
<tr>
<td><strong>High case</strong></td>
<td>This scenario assumes a faster economic recovery, lower efficiency gains and greater penetration of gas in the power sector. Total gas demand is forecast to reach 760 bcm by 2035.</td>
</tr>
<tr>
<td><strong>Low case</strong></td>
<td>This scenario assumes that gas demand declines in mature economies continue, however this is offset by increased energy intensity in emerging European economies, notably Turkey and new uses for gas such as LNG bunkering. Total gas demand is forecast to grow, albeit at a slower rate. Gas demand grows from 502 bcm in 2013 to 544 bcm in 2035.</td>
</tr>
</tbody>
</table>

Table 1.5 contains estimated future demand for natural gas in Europe for all WM scenarios to 2035. It also contains forecast European production over the same period. As with the IEA report, it shows demand for natural gas increasing at the same time that European production is declining.

Table 1.5 WM: Predicted Gas Demand in Europe (bcm)

<table>
<thead>

</tr>
</tbody>
</table>

Reduced domestic gas production means that under the Base Case Scenario approximately two thirds of European forecast demand in 2035, or 438 bcm per year in absolute terms, will have to be met by natural gas imports (Ref. 1.7).
Table 1.6 contains the predicted net import requirements for all future scenarios, given forecast demand.

**Table 1.6 WM: European Gas Demand minus Domestic Production: Net Import Requirements (bcm)**

**Summary**

The South Stream Offshore Pipeline will respond to increased demand for foreign natural gas by providing transport capacity of 63 bcm per year, which will be directed to the European supply network.

Results from the IEA report suggest that this capacity could contribute to the expected increased reliance on imported natural gas resulting from the combination of declining EU production and increased demand in 2035 under the New Policy scenario (Figure 1.3).

**Figure 1.3 EU Gas Demand and Import Forecast – New Polices Scenario 2010-2035 (bcm)**
The results from the WM report suggest that the South Stream Offshore Pipeline will contribute to the expected increase in imported natural gas resulting from the combination of declining European production and increased demand in 2035, under the Base Case scenario (see Figure 1.4).

**Figure 1.4 Europe Gas Demand and Import Forecast – Base Case 2013-2035**

![Bar Chart](chart.png)

Table 1.7 contains the forecast contribution of the South Stream Offshore Pipeline to meeting future import demand for natural gas, for all IEA and WM scenarios. It shows that the contribution of the South Stream Offshore Pipeline is estimated to range from 11% to 22% under the future scenarios presented in the IEA and WM reports.

<tr>
<td>Low case</td>
<td>18%</td>
</tr>
</tbody>
</table>

It should be noted that these forecasts are based on the pipeline operating at full capacity.

Although both the IEA ‘New policy’ and WM ‘Base case’ scenarios result approximately in the same estimated contribution being made to total import demand (i.e. 16% and 14% respectively), this does not necessarily reflect agreement between the two estimates. As previously stated, the IEA and WM forecasts are not directly comparable because different future scenarios and geographical scopes have been used.

#### 1.1.2 South Stream Offshore Pipeline Proponent

The South Stream Offshore Pipeline is being developed by South Stream Transport B.V. (South Stream Transport), an international joint venture established on 14 November 2012 in Amsterdam, the Netherlands, for the planning, construction, and subsequent operation of the offshore gas pipeline through the Black Sea. The Russian company Gazprom holds a 50% stake in South Stream Transport, the Italian company Eni has a 20% stake and the French energy company EDF Group and German company Wintershall each hold 15%.

1.1.2.1 Gazprom, Russia

Gazprom is the world’s largest supplier of natural gas, accounting for approximately 15% of global gas production in 2012. It was established as a joint stock company in 1993, and is partly owned by the Russian state (50.002%). The company’s core activities include the exploration, production, transportation, storage, processing and marketing of hydrocarbons, as well as the generation and marketing of heat and electric power.

Gazprom controls 72% of Russian gas reserves producing 74% of all Russian natural gas output. A leading company in the construction and operation of gas pipelines, it controls the world’s largest gas transmission network – the United Gas Supply System of Russia with a total length of over 168 thousand kilometres.

---

^4 Previously, the Project was developed by Gazprom during 2009-2011, and then by South Stream Transport AG during 2011-2012. The head office of South Stream Transport was then moved from Switzerland to the Netherlands, where the Shareholders established South Stream Transport B.V. in November 2012.
1.1.2.2 Eni, Italy

Headquartered in Italy, Eni is one of the world’s major integrated energy companies, operating in the sectors of oil and gas exploration and production, international gas transportation and marketing, power generation, refining and marketing, chemicals and oilfield services.

1.1.2.3 EDF Group, France

The EDF Group, one of the leaders in the European energy market, is an integrated energy company active in all areas of the business: generation, transmission, distribution, energy supply and trading, including provision of natural gas supplies. The EDF Group is the leading electricity producer in Europe.

1.1.2.4 Wintershall, Germany

Wintershall, based in Kassel, Germany, is a wholly-owned subsidiary of BASF. The company has been active in the exploration and production of crude oil and natural gas for over 80 years and is now Germany’s largest crude oil and natural gas producer.

1.2 Project Overview

The Russian Sector extends approximately 230 km in length from a location approximately 10 km south of the town of Anapa, in the Krasnodar Krai (or Region), to the border between the Russian and Turkish EEZs (Figure 1.2) in the Black Sea. Of the 230 km, approximately 5 km are onshore, 50 km are within the territorial waters of the Russian Federation, and 175 km are within the EEZ of the Russian Federation.

The coastal region surrounding Anapa is a popular holiday destination because of its beaches, warm climate and the presence of sites of cultural, historical and natural interest. Anapa is categorised by Russian Federation legislation as a “health-improving” resort area5, and has a sanitary protection area (SPA) that consists of three distinct zones, each with different restrictions. The proposed Project infrastructure does not fall within any zones of the SPA. Further details on the SPA are included in Chapter 2 Policy, Regulatory and Administrative Framework.

Land use in the vicinity of the Project is largely agricultural and includes a number of vineyards. The Project is also located in proximity to the Utrish State Nature Reserve but does not traverse its territory. The Utrish reserve is located approximately 4 km southeast of the landfall section and owes its protected status to the natural habitats that include botanical and faunal species of local, national, and international importance. The majority of the Project is located offshore, as depicted in Figure 1.5.

5 The boundaries and management of this area were established by the Decree of the Council of Ministers of the Soviet Union dated January 30, 1985 N 45 (Ref. 1.8).
This document has been prepared in accordance with the scope of URS' appointment with its client and is subject to the terms of that appointment. URS accepts no liability for any use of this document other than by its client and only for the purposes for which it was prepared and provided. Only written dimensions shall be used.

LEGEND
- Russian Sector of South Stream Offshore Pipeline
- Proposed landfall section pipelines
- Landfall facilities
- Proposed microtunnels
- Proposed offshore pipelines
- Microtunnel entry shaft
- Microtunnel exit pit
- Project Area - landfall section (indicative)
- Project Area - nearshore section (indicative)
- Project Area - offshore section (indicative)
- Russian Territorial Waters boundary
- Exclusive Economic Zone boundary
- Isobaths

NOTE
Note that for the marine ecology assessment, the nearshore is considered to also include the area from the shore to 23 m water depth, because these two sections of the Project Area are ecologically contiguous.
Further details of the Project Area are provided in the Section 1.2.1. In summary, the four pipelines are routed along the continental shelf, down the continental slope, and then along the abyssal plain to the border of the Russian and Turkish EEZs (Figure 1.5). The water depth and the physical characteristics of the Black Sea present a challenge for the Project and have influenced a number of key technical decisions, including the routing of the pipelines and the siting of the landfall facilities.

1.2.1 Project Area

For the purpose of this ESIA Report, the Project is divided into three sections: the landfall section, the nearshore section and the offshore section (see Figure 1.5 and Figure 1.6). Each of these is discussed in turn in Sections 1.2.1.1 to 1.2.1.3.

Figure 1.6 South Stream Offshore Pipeline – Russian Sector

1.2.1.1 Landfall Section

The landfall section is approximately 4 km long and consists of permanent landfall facilities, which will include metering equipment, pipeline inspection gauge (PIG) trap facilities, and emergency shutdown valves (ESDs), along with the four buried pipelines. Within this section, 2.4 km of the pipelines will be buried with a minimum soil cover of 1.5 metres (m).

As there is a steep sea cliff at the shore crossing, for the remaining 1.4 km the pipelines will be housed in microtunnels. The microtunnels will terminate approximately 400 m from the coast (the exit point) in a water depth of approximately 23 m. The area of the landfall section is defined by the maximum operational safety exclusion zone of 410 m width surrounding the...
Pipeline and the landfall facilities. While the entirety of this area may not experience physical impacts, there will be restrictions on future land use and development within the operational safety exclusion zone.

Deliveries of pipe and equipment to the landfall construction areas will be made by road. The Project will require the upgrade of some existing roads and will also require some new roads to be built for access during construction. Further detail is provided in Chapter 5 Project Description.

1.2.1.2 Nearshore Section

The nearshore section commences at the exit point of the microtunnels, located approximately 400 m from the coast at a water depth of approximately 23 m and extends approximately 425 m to a water depth of 30 m. The lateral boundaries of the nearshore section consist of a corridor 3 km either side of the outermost pipeline. From the microtunnel exit point, the pipelines will be buried in trenches to a depth of approximately 2.5 to 3 m for a distance of approximately 170 m. From here, out to the edge of the nearshore section, the pipelines will be coated in concrete and laid directly on the seabed.

Construction activities associated with the installation of the pipelines in the nearshore section will require a number of seagoing vessels. All construction activities in this section of the Project will be carried out at sea.

The pipeline construction work will require support from an onshore support facility, known as a marshalling yard, for the inbound delivery, storage and load out of pipe, plant and equipment. The marshalling yards will be located in Bulgaria and are discussed in the separate ESIA Report for the South Stream Offshore Pipeline – Bulgarian Sector.

1.2.1.3 Offshore Section

The offshore section has an overall length of approximately 225 km. It extends from the edge of the nearshore section at 30 m water depth to the border of the Russian and Turkish EEZs in the Black Sea. The lateral boundaries of the Project Area consists of a corridor 3 km either side of the outermost pipelines, beginning at the boundary of the nearshore section to the 600 m water depth contour. The corridor decreases to 2 km width either side of the outermost pipeline from the 600 m water depth contour to the Russian EEZ boundary.

In this section the pipelines are laid along the continental shelf, down the continental slope, and across the abyssal plain. The abyssal plain lies at the base of the continental slope and gently slopes to the west to a maximum depth of approximately 2,200 m. In the offshore section, the pipelines will be laid directly on the seabed. The pipelines will be coated in concrete out to a water depth of approximately 88 m.

---

6 As defined by the Construction Phase safety exclusion zone around construction vessels.
1.2.2 Associated Facilities

Associated Facilities are defined by the OECD Common Approaches' (Ref. 1.9) as follows:

"...facilities that are not a component of the project but that would not be constructed or expanded if the project did not exist and on whose existence the viability of the project depends; such facilities may be funded, owned, managed, constructed and operated by the buyer and/or project sponsor or separately from the project."

The Equator Principles (EP) (Ref. 1.10) reference Associated Facilities indirectly through the International Finance Corporation (IFC) Performance Standards (PSs) (Ref. 1.11). The Project's Associated Facilities are consistent with these definitions and include:

- The Russkaya compressor station (CS) and the four pipelines connecting the compressor station with the Project, which are located immediately upstream of the Project in Russia and that are developed and managed by Gazprom Invest (GPI); and
- Designated existing quarries for sourcing material / aggregates, where those existing quarries would require significant expansion for the sole purpose of supplying the Project.

1.2.2.1 Russkaya Compressor Station

The landfall facilities will be connected to the Russkaya CS via four 3.2 km onshore pipelines (Figure 1.7). The Russkaya CS and the four 3.2 km connecting pipelines are not part of the Project and will be designed and installed as part of a separate project known as "Expansion of the United Gas Supply (UGS) System" which is being constructed by Gazprom Invest. However, the CS provides the pressure necessary to drive gas through the Project pipelines across the Black Sea, and therefore it is considered to be an associated facility.

The Russkaya CS has followed a separate engineering and approval process, which included the execution of an EIA and review and approval by Russian authorities. The findings of the EIA are summarised in Appendix 20.1: Environmental Impacts of Associated Facilities: Russkaya Compressor Station (CS) of this ESIA Report, along with a benchmarking of the EIA against international standards. Further consideration of the Russkaya CS is also given in Chapter 20 Cumulative Impact Assessment, including cumulative impacts associated with the construction and operation of the Russkaya CS amongst other nearby developments (see Section 1.4.2). Further details on the Project and Associated Facilities including proposed activities that will be carried out are provided in Chapter 5 Project Description.

---

7 OECD Common Approaches are the primary environmental and social standards applicable to the Project. Further details are provided in Chapter 2 Policy, Regulatory and Administrative Framework.

8 IFC PS1 paragraph 8: Associated Facilities are defined as facilities that are not funded as part of the project and that would not have been constructed or expanded if the project did not exist and without which the project would not be viable.
1.2.3 South Stream Pipeline System

The South Stream Pipeline System consists of one offshore and four onshore components as summarised in Table 1.8.

**TOTAL**

| **Length**: 2,456 km **Compressor Stations**: 8 |

The components of the South Stream Pipeline System on the territory of Bulgaria, Serbia, Hungary, and Slovenia are separate projects and are subject to separate EIAs in compliance with national legislation.
1.2.4 South Stream Offshore Pipeline Phases and Timeline

South Stream Offshore Pipeline development includes five key phases:

- **Feasibility Phase** (2007 to early 2012) initiated by Gazprom. This phase involved the development of Feasibility Studies in which a number of gas pipeline routes and landfall options were assessed and a preliminary engineering (conceptual) design was developed. The phase also included a Preliminary EIA developed for Russian permitting requirements that was approved by the State Environmental Expert Review on 24 September 2010;

- **Development (or Design) Phase** (late 2011 to late 2013) undertaken by South Stream Transport. This phase involves development of the Front End Engineering and Design (FEED) together with Russian Project Design Documentation (Proekt) and national EIA. This phase also includes development of the ES1As and Environmental and Social Management Plan (ESMP) to meet the international standards and guidelines for financing;

- **Construction and Pre-Commissioning Phase** (2014 to end 2017). This phase will involve construction activities and a number of activities, known as pre-commissioning activities, which will be undertaken after each pipeline has been installed to ensure that the pipelines meet operational requirements;

- **Operational Phase (consisting of Commissioning and Full Operational Phase)** (2017 to 2065). The Project will have an operational design life of 50 years; and

- **Decommissioning Phase** (2065 onwards).

An indicative timeline for the South Stream Offshore Pipeline is provided in Figure 1.8.
1.3 EIA and ESIA Requirements for the Project

The Project is subject to impact assessments for both national regulatory and international financing requirements. As the Project is located within the territory and waters of the Russian Federation, the Project has also submitted EIA documentation in accordance with Russian Federation legal requirements.

As the Project will be subject to project finance, this ESIA Report is aligned with the environmental and social performance standards and guidelines of international financing.

The environmental and social standards and guidelines of the Project are as follows:

- The OECD Common Approaches on the Environment and Officially Supported Export Credits, dated 2012 (Ref. 1.9);
- The Equator Principles III (2013) (Ref. 1.10);
- Japan Bank for International Cooperation (JBIC) Guidelines for Confirmation of Environmental and Social Consideration, dated 2012 (Ref. 1.12); and
- The IFC Performance Standards (2012) and World Bank Group EHS Guidelines (Ref. 1.11), which underpin the OECD Common Approaches and Equator Principles III.9

This ESIA Report has been prepared by URS Infrastructure and Environment UK Limited (URS) in accordance with the international standards and guidelines described above. Peter Gaz (a registered Russian company) prepared the EIA documentation required under Russian law.

Information from the national EIA process preceded and therefore informed the ESIA. URS further addressed a number of issues that were necessary to meet requirements and standards for international financing. URS and Peter Gaz coordinated the technical development of the ESIA and EIA chapters to ensure consistency of methodology, approach and content as far as practicable.

Nevertheless, there are differences between the two documents in relation to their content and in the quantification of some impacts. These variances are due mainly to the difference between the Russian Federation EIA regulatory requirements and conventional ESIA practice as set out in the standards and guidelines for international financing.

1.4 Objectives of this ESIA

In accordance with the Equator Principles, the OECD Common Approaches and JBIC Guidelines, the objectives of this ESIA Report are based on those of IFC PS1: Assessment and Management of Environmental and Social Risks (Ref. 1.13), which are:

---

9 As per IFC PS, South Stream Transport is committed to implementing Good International Industry Practice (GIIP) in relation to environmental and social performance in all phases of the South Stream Offshore Pipeline. Further details on the standards and guidelines relevant to this ESIA Report are included in Chapter 2 Policy, Regulatory and Administrative Framework.
• “To identify and evaluate environmental and social risks and impacts of the project;

• To adopt a mitigation hierarchy to anticipate and avoid, or where avoidance is not possible, minimize, and, where residual impacts remain, compensate / offset for risks and impacts to workers, affected communities, and the environment;

• To promote improved environmental and social performance of clients through the effective use of management systems;

• To ensure that grievances from affected communities and external communications from other stakeholders are responded to and managed appropriately; and

• To promote and provide means for adequate engagement with affected communities throughout the project cycle on issues that could potentially affect them and to ensure that relevant environmental and social information is disclosed and disseminated.”

1.4.1 Area of Influence of the Project

This ESIA Report has been prepared taking into consideration the definition of Project Area of Influence provided by IFC PS1 (Ref. 1.13) which states:

"Where the project involves specifically identified physical elements, aspects, and facilities that are likely to generate impacts, environmental and social risks and impacts will be identified in the context of the project’s area of influence. This area of influence encompasses, as appropriate:

• The area likely to be affected by:
  
  o The project and the client’s activities and facilities that are directly owned, operated or managed (including by contractors) and that are a component of the project;
  
  o Impacts from unplanned but predictable developments caused by the project that may occur later or at a different location; or
  
  o Indirect project impacts on biodiversity or on ecosystem services upon which Affected Communities’ livelihoods are dependent.

• Associated Facilities, which are facilities that are not funded as part of the project and that would not have been constructed or expanded if the project did not exist and without which the project would not be viable; and

• Cumulative impacts that result from the incremental impact, on areas or resources used or directly impacted by the project, from other existing, planned or reasonably defined developments at the time the risks and impacts identification process is conducted.”

Consistent with the definition provided above, the Project Area of Influence includes those areas likely to be affected by the main Project facilities (including the Project Area and Associated Facilities described above), and in the case of cumulative impacts, incremental impacts from other developments, unrelated to the Project, that will take place within the vicinity of the Project Area.

The assessment of the potential environmental and social impacts of Associated Facilities has been carried out taking into account the timing and location of their construction, and reasonable efforts have been made to benchmark against relevant international standards using
the available information. In the event of risks and impacts in the Project’s Area of Influence resulting from a third party’s actions, South Stream Transport will address those risks and impacts in a manner commensurate with South Stream Transport’s control and influence over the third parties, and with due regard to conflict of interest.

1.4.2 Cumulative and Transboundary Impacts

While the activities associated with a single project may or may not result in significant impacts, the “cumulative” effects of simultaneous projects, may be more significant and should be considered within an ESIA. This ESIA adopts the IFC PS (Ref. 1.13) definition of cumulative impacts which are defined as:

“Cumulative impacts are those that result from the incremental impact of the Project when added to other existing, planned and reasonably predictable future projects and developments.”

Cumulative impacts may occur as a result of interactions between any residual (i.e. post-mitigation) Project impacts, and the impacts of other activities or developments in the vicinity of the Project Area.

The assessment of cumulative impacts includes the Russkaya CS and well as a number of known and proposed developments within the proximity of the Project. Further details of the approach and schemes considered within the cumulative impact assessment are provided in Chapter 20 Cumulative Impact Assessment.

Where specific impacts are anticipated to extend across Project Area boundaries (see Section 1.2.1), the ESIA Report provides a description of the potential geographical extent associated with the impact. In particular, the potential for transboundary impacts (i.e. the potential for the Project Area of Influence to extend across Russian national boundaries) is discussed in Chapter 21 Transboundary Impact Assessment.

1.4.3 Structure of the ESIA Report

The ESIA chapter titles and a summary of the approach and content are provided below:

Table 1.9 ESIA Report Structure

<table>

Report Structure

2. Policy, Regulatory and Administrative Framework

The chapter includes:

- A description of the Russian regulatory process to be followed for all Project Activities;
- Identification of Russian environmental and social legislation of relevance to the Project;
- Identification of international treaties and conventions to be adhered to; and
- Identification of international standards and guidelines of relevance to the Project.

3. Impact Assessment Methodology

The chapter includes:

- A description of the ESIA process; and
- A description of the impact assessment methodology and of the adopted impact significance criteria.

4. Analysis of Alternatives

A comparison of the developmental options considered in the Project design phase including the ‘zero’ option, alternative gas transportation options, routing options and facility and operational options considered.

5. Project Description

A detailed description of:

- Onshore and offshore infrastructure;
- Construction methodologies and staging;
- Hydrotesting and commissioning works;
- Operational conditions and maintenance requirements; and
- Decommissioning process.

6. Stakeholder Engagement

A summary of all Project consultation undertaken, the issues raised, and where these issues have been addressed within the ESIA documentation. The Chapter also describes future consultation activities.

7. Physical and Geophysical Environment

A description of the methods used and results from surveys and secondary data review to define baseline conditions for the physical and geophysical environment. This incorporates a number of aspects including seismology, geology, electromagnetic fields, and ionising radiation.

- Assessment of potential impacts arising from the management of wastes;  
- Identification of practicable mitigation measures to be applied; and  
- Assessing the significance of the residual impacts post mitigation implementation. |
| 19. Unplanned Events | The chapter includes:  
- Description of the potential unplanned events and impacts that may arise as a result of the Project;  
- Identification of design control and mitigation measures able to be undertaken; and  
- Discussion of the residual risk posed by the identified unplanned events and relevant monitoring requirements. |
| 20. Cumulative Impact Assessment | A summary of the potential cumulative impacts as a result of Project associated development and other existing and proposed developments in the vicinity of the Project Area. |
| 21. Transboundary Impact Assessment | A description of the potential for transboundary impacts that may arise as part of the Project. |
| 22. Environmental and Social Management | An outline of the key management measures, processes and monitoring requirements to be undertaken, based on the outcomes of the impact assessment. |
| 23. Conclusions | A summary of the residual impacts arising as a result of the Project and provision of overall conclusions as to the overall environmental and social significance of impacts arising from the Project. |

Complete.

As a supplement to the ESIA Report, a non-technical summary (NTS) has been prepared. The NTS describes the findings of the ESIA Report, including the potential environmental and social impacts, and actions that will eliminate, reduce, or mitigate those impacts.
1.5 Related South Stream Offshore Pipeline Impact Assessment Documents

In addition to this ESIA Report and the EIA documentation that have been prepared specifically for the Russian Sector, additional impact assessment documentation has been prepared for the other host countries affected by the South Stream Offshore Pipeline, including:

- A Turkish EIA Report to meet Turkish legislative requirements;
- A Turkish ESIA Report to address international financing requirements for the Turkish Sector;
- A Bulgarian EIA Report to meet Bulgarian legislative requirements; and
- A Bulgarian ESIA Report to address international financing requirements for the Bulgarian Sector.

2 Policy, Regulatory and Administrative Framework

2.1 Introduction

This chapter provides an overview of the policy, regulatory and administrative framework relevant to the Project.

As the Project is located within the territory and waters of the Russian Federation, this ESIA Report will take into consideration relevant Russian Federation regulatory requirements and administrative structures.

South Stream Transport is also committed to implementing Good International Industry Practice (GIIP) in relation to environmental and social performance during all Project Phases: Construction and Pre-Commissioning, Operational and Decommissioning Phases.

As part of GIIP, various guidance documents are referred to within this ESIA Report as listed below. Measures contained therein will be adopted as project standards where relevant and practical:

- Sector Guidance Note Integrated Pollution Prevention and Control (IPPC) S1.2 (Guidance for the Gasification, Liquefaction and Refining Sector) (Ref.2.1);
- The Oil and Gas Industry: Operating in Sensitive Environments 23 – International Petroleum Industry Environmental Conservation Association (IPIECA) (Ref. 2.2); and
- Environmental Management in Oil and Gas Exploration and Production 1997 – United Nations Environment Program Industry and Environment (UNEP IE) and the Oil Industry International Explorations and Production Forum (E&P Forum) (Ref. 2.3).

The Project is being carried out in accordance with standards and guidelines for international financing, including those for Environmental and Social Impact Assessment (ESIA). This commitment is reflected in South Stream Transport’s Health and Safety, Security and Environmental Policy.

This chapter includes an overview of the following:

- South Stream Transport’s relevant corporate policies (Section 2.2);
- Russian Federation regulatory and administrative structures (Section 2.3);
- Russian Environmental Impact Assessment (EIA) process and other federal legislation relevant to the Project (Section 2.4);
- Russian local and regional legislative requirements relevant to the Project (Section 2.5);
- International and regional conventions signed or ratified by Russia relating to environmental protection, sustainable development, cultural heritage, socio-economic and human rights that are relevant for the Project (Section 2.6); and
• International standards and guidelines for financing that the Project will be undertaken in accordance with (Section 2.7), namely:
  
  o The Organisation for Economic Co-operation and Development (OECD) Revised Council Recommendation on Common Approaches on the Environment and Officially Supported Export Credits (OECD Common Approaches) (Ref. 2.4);
  o The Equator Principles (EP) III (Ref. 2.5);
  o Japan Bank for International Cooperation (JBIC) Guidelines for Confirmation of Environmental and Social Consideration. (Ref. 2.6); and
  o The International Finance Corporation (IFC) Performance Standards (PS) and Word Bank Group EHS Guidelines, which underpin the OCED Common Approaches and EPIII (Ref. 2.7).

2.2 Corporate Policies

South Stream Transport has two policies that are relevant to this ESIA Report: a Health and Safety, Security, and Environmental Policy, and a Corporate Social Responsibility and Sustainability Policy. Both were signed into action by South Stream Transport’s Chief Executive Officer (CEO) on 10 October 2013. The policy text is provided verbatim below and copies of the signed policies are available upon request.

2.2.1 Health and Safety, Security and Environmental Policy

The South Stream Transport Health and Safety, Security and Environment Policy is provided verbatim below.

"South Stream Transport B.V. (South Stream Transport) aims to provide reliable and secure energy to the European market responsibly and sustainably whilst creating value for society. We will do this by creating a major new infrastructure through the Black Sea: a gas pipeline that is safe, reliable and efficient.

South Stream Transport is committed to integrating social, economic, environmental and governance considerations into the everyday conduct of our business as we design, build and operate the South Stream Offshore Pipeline.

We are committed to environmentally and socially responsible management, in accordance with national, international and EU legislation, and internationally recognised standards for health and safety, security and environmental and social performance.

Our guiding principles are to:

• Seek to achieve ZERO incidents and consequences related to health and safety, security and environment (HSSE);
• Ensure compliance with the requirements of applicable laws and regulations;
• Ensure compliance with applicable national and international standards and industry good practice;"
• Set clear and transparent HSSE objectives and targets, and plan, implement and monitor performance in order to realise these goals;

• Prevent pollution and protect the environment by minimising adverse impacts throughout the project lifecycle;

• Manage construction and operational activities in a responsible and sustainable manner;

• Provide a safe and healthy workplace for employees, contractors and other persons to prevent injury or ill health, including definition of HSSE roles and responsibilities, measures to prevent injuries and ill health or minimise risks, information, instruction and training, and investigation of any incidents;

• Engage with Government and local authorities, Non-Governmental Organisations, local communities and members of the public, and other interested parties;

• Communicate and work closely with employees, contractors and other interested parties to ensure their understanding and shared commitment to conformance with this policy; and

• Ensure continual improvement of HSSE performance.

This corporate policy applies to all our staff and across all our business activities, it guides our strategy, management, decisions and actions, it is incorporated into the documents governing our relationships with our suppliers and contractors, and guides our relationships with joint venture and other business partners.

We recognize that leadership and commitment from senior management is an essential component of success, and we are committed to ensuring that all senior executives and directors of the Company are fully conversant with, and committed to, our policy and goals.”

2.2.2 Corporate Social Responsibility and Sustainability Policy

The South Stream Transport Health and Safety, Security and Environment Policy is provided verbatim below.

"South Stream Transport aims to provide reliable and secure energy to the European market responsibly and sustainably whilst creating value for society. We will do this by creating a major new infrastructure through the Black Sea - a gas pipeline that is safe, reliable and efficient.

South Stream Transport is committed to integrating social, economic, environmental and governance considerations into the everyday conduct of our business as we design, build and operate the South Stream Offshore Pipeline.

We are committed to good corporate citizenship in all the countries in which we operate, and intend to enter into transparent and respectful dialogue with our stakeholders enabling us to take their interests into account in our long term planning and everyday decision-making.

We aim to make the South Stream Offshore Pipeline safe, socially responsible and economically beneficial by:

• Contributing to reducing climate change by delivering natural gas as a clean and efficient fossil fuel;
Preserving the Black Sea environment, biodiversity and avoid any irreversible impact;

Minimising our negative impacts and enhancing our positive impacts on the environment and communities;

Applying good international industry practice in assessing and addressing any potential impacts;

Adhering to international construction and quality standards in design, building and operating the gas pipeline and promoting best international safety standards and reducing risks for employers and local communities; and

Development of opportunities for employers, suppliers and the wider community.

Our guiding principles are to:

Guaranteeing the sustainability of its activities by applying a long-term strategy, providing a coherent framework for innovation development as well as integrated risk management and risk prevention management strategy;

Respecting internationally recognized Human Rights in our own operations and promoting the respect of the aforementioned rights with regard to activities assigned to or carried out with Business Partners and in our relationships with stakeholders; and

Conducting business with loyalty, fairness, transparency, honesty, and integrity and in compliance with the laws, regulations, similar mandatory requirements, and international standards and guidelines, both domestic and foreign that apply to its business.

In operating, we shall respect the UN Global Compact Principles, including:

Protection of international human rights;

Rights to free association, collective bargaining and employment non-discrimination;

Protection and preservation of the environment; and

Elimination of corruption, including bribery and extortion.

This policy applies to all our staff and across all our business activities, it guides our strategy, management, decisions and actions, it is incorporated into the documents governing our relationships with our suppliers and contractors, and guides our relationships with joint venture and other business partners.

We recognize that leadership and commitment from senior management is an essential component of success, and we are committed to ensuring that all senior executives and directors of the Company are fully conversant with, and committed to, our policy and goals.”
2.3 Overview of Russian Federation Regulatory and Administrative Structures

2.3.1 Federal Government Structure

The Russian Federation is structured as a multi-party representative democracy, with the federal government composed of three branches (Figure 2.1):

- **Legislative**: This is known as the Federal Assembly and is comprised of two houses, the 450-member State Duma and the 166 member Federal Council. It is responsible for adopting federal law, declaring war, approving treaties, and has budgetary authority and the power to impeach the President;

- **Executive**: The President is the commander-in-chief of the military and can veto legislative bills before they become law on the basis that such rulings do not contravene their constitution and federal laws already in place; and

- **Judicial**: This comprises the Constitutional Court, Supreme Court, Supreme Court of Arbitration and lower federal courts (Regional, District and Magistrate Courts). The Constitutional Court is the only judicial body with the ability to rule on the constitutional law and examine the interactions of the other courts. Judges are appointed by the Federal Council on the recommendation of the President.

Figure 2.1 Russian Federal Government’s Structure
In general, the regional and federal state authorities follow a similar structure of administration, with regional government bodies reproducing the major features of federal government bodies. However, local government structures vary amongst municipalities with only general principles of organisation being established by federal and regional legislation.

2.3.2 Administrative Units

The Russian Federation is made up of 83 federal administrative subje cts (units), which are classified as territories (Krais), regions (Oblasts), cities of federal importance, autonomous regions and autonomous area (Ref. 2.7) (Figure 2.2). Each administrative unit is equally represented in the Federation Council, with two delegates each.

These federal administrative units are grouped together into eight federal districts. These federal districts were created in 2000 to assist in controlling laws and practices of the administrative units (Ref. 2.8). The administrative units are also grouped together into economic regions. Each economic region is made up of administrative units with comparative economic conditions (Ref. 2.9).

The landfall section of the Project lies within Krasnodar Krai, which is grouped within the Southern Federal District and within the North Caucasus economic region. The landfall section of the Project lies within Krasnodar Krai, which is grouped within the Southern Federal District and within the North Caucasus economic region.

2.3.3 Government Ministries, Agencies and Services

National level government organisations (ministries, agencies, services) with EIA regulatory functions relating to the Project include:

- Ministry of Natural Resources and Environment (MNRE);
- Ministry of Regional Development;
- Federal service on customers' rights protection and human well-being surveillance; and
- Russian Federal Fisheries Agency (FFA).

Federal ministries, such as the MNRE, create policies and legislation and perform compliance assurance functions. The MNRE also coordinates and supervises the activities, within its jurisdiction, of the following (Ref. 2.10):

- Federal Service for Hydrometeorology and Environmental Monitoring;
- Federal Service for Supervision of Natural Resource Management (Rosprirodnadzor);
- Federal Agency for Water Resources (Rosvodresursy);
- Federal Agency for Subsoil Management (Rosnedra); and
- Federal Agency for Forestry (Rosleskhoz).

The federal services and agencies listed above supervise environmental management and issue licenses and permits for activities under their jurisdiction.
Federal ministries, such as the MNRE, create policies and legislation and perform compliance assurance functions. The MNRE also coordinates and supervises the activities, within its jurisdiction, of the following (Ref. 2.10):

- Federal Service for Hydrometeorology and Environmental Monitoring;
- Federal Service for Supervision of Natural Resource Management (Rospririodnadzor);
- Federal Agency for Water Resources (Rosvodresursy);
- Federal Agency for Subsoil Management (Rosnedra); and
- Federal Agency for Forestry (Rosleskhoz).

The federal services and agencies listed above supervise environmental management and issue licenses and permits for activities under their jurisdiction.

There is also a Russian Federal Service for Environmental, Industrial and Nuclear Supervision (Rostekhnadzor). Rostekhnadzor performs supervision of the following:

- Safe work practices relating to the use and protection of mineral resources;
- Industrial safety;
- Safe use of nuclear power;
- Safety of electrical and heating units and networks;
- Safety of hydroelectric facilities at industrial and power generation facilities; and
- Safety in production, storage and use of industrial explosives.

2.3.4 Hierarchy of Laws

The hierarchy of Russian Federation legislation can be summarised as follows:

- **Level 1**: Federal Laws and Federal Codes are created by the State Duma (the lower house of the Federal Assembly of Russia) and then adopted by the Federal Council of Russia (the upper house of the Federal Assembly of Russia);

- **Level 2**: Bylaws (includes three groups):
  - **Group 1**: Presidential decrees and directives – In accordance with Article 90 of the Constitution of the Russian Federation (Ref. 2.7), the Russian Federation President can issue decrees and directives. Decrees are legal acts that concern all jurisdictions. Directives are acts that concern specified entities;
  - **Group 3**: Acts of the Ministries and other executive federal / government agencies – All environmental protection ministries and agencies have the right to issue legal and regulatory acts within the scope of their competence. Such acts are binding upon any
other ministries or agencies, individuals or legal persons, and are issued as orders, resolutions, instructions, rules, provisions, articles, and directives.

2.4 Federal Legislation

2.4.1 The Constitution

The Constitution of the Russian Federation came into force on 25 December 1993 (Ref. 2.7), following a national referendum. It is the primary and fundamental statement of law and is based on world standards for human rights and basic principles of democratic state-building, such as neutrality of the state, competitive elections, and separation of powers. The Constitution establishes a semi-presidential system, whereby the President is the head of state and the Prime Minister is the head of government.

The President is elected by popular vote for a six-year term and can be eligible for a second term. The President, with the parliament's approval, is responsible for appointing the Prime Minister. Government ministers (such as the Premier and his deputies) are also appointed by the President on the recommendation of the Prime Minister.

2.4.2 Environmental and Socio-Economic Legislation and Statutory Requirements

Associated with legal requirements for EIA, is a range of statutory requirements and guidelines.

Russian environmental and social legislation applicable to the Project is outlined in Appendix 2.1. Any specific requirements arising out of this legislation that influence the impact assessment process are detailed in the relevant technical chapters of this ESIA Report. A Health, Safety, Security and Environment (HSSE) Legal Register has been produced for the Project which lists all legislation relevant to all stages of the Project, not only those covered within this ESIA Report. This HSSE register has formed the basis of Appendix 2.1 and the legislation detailed in each technical chapter of this ESIA Report.

2.4.2.1 Legal Framework of the Sanitary Protection Area of Anapa

The Resort town of Anapa was assigned the status of a federal resort by President Decree No. 1954 dated 22 September 1994 (Ref. 2.11). It was given this status due to its recreational value as a ‘health improving’ (spa) resort area.

The original boundaries of the area were established by Decree of the Council of Ministers of the Soviet Union dated 30 January 1985, No. 45 (Ref. 2.12). The Decree specifies the overall boundary of the area and three distinct zones with different levels of protection, detailed below:

- **First Exclusion Zone:** within this zone, the only permitted works are those associated with the therapeutic use of the natural resources. All commercial activities not connected to the natural resources of the area or which may cause an adverse impact on the area are prohibited;
• **Second Limitation Zone**: within this zone, construction is allowed for works that are directly related to the development and improvement of the natural resources of the area. All activities that could cause pollution to soil, water and air, damage to forests, green areas, increase erosion processes or adversely impact any natural health resources (water bodies etc.) are prohibited; and

• **Third Monitored Zone**: within this zone, works which do not adversely impact the natural resources and the sanitary conditions of the resort are permitted.

The Project had initially been located within zones 1, 2 and 3 of the sanitary protection area of Anapa. To allow construction of the pipelines, an application to change the boundaries of this area was made and approved by the Russian Federal Government Decree No. 1087 dated 22 October 2012 ‘on the partial change of Decree of the Council of Ministers of Russian Soviet Federative Socialist Republic (RSFSR) No.45 of 30 January 1985’ (Ref. 2.12).

Although the Project no longer falls within any of the sanitary protection area zones, the proximity of this protected area has been considered in the relevant technical chapters of this ESIA Report, including Chapter 8 Terrestrial Soil and Groundwater, Chapter 9 Air Quality, Chapter 10 Noise and Vibration, Chapter 11 Terrestrial Ecology and Biodiversity, Chapter 12 Marine Ecology and Chapter 17 Ecosystem Services. The revised boundaries of the sanitary protection area are shown in Figure 2.3.

The restrictions associated with these three zones were specified by the Russian Federation Government Decree No. 1425 dated 07 December 1996 (Ref. 2.13).

### 2.4.2.2 Anapa Bank

The Anapa Bank was initially designated as a restricted fishing area in 1986 by a Decree of the Ministry of Fisheries of the Union of Soviet Socialist Republics (USSR), No. 321, 18 June 1986 (Ref. 2.14). The 1986 Decree imposed a ban on trawl fishing to ensure that there was a steady supply of fish for a fish farm that was planned at the Utrish state nature reserve. The proposed offshore pipelines of the Project fall within the Anapa Bank as shown in Figure 2.4.

The originally designated area of Anapa Bank included a deeper water section on the continental shelf (heading onto the continental slope\(^1\)), in which trawling for species such as anchovy and sprat was seasonally restricted. However, the geographic area was reduced to 730 km\(^2\) by the Resolution of the Scientific Fishery Council of the Azov and Black Sea Basin in 1999 (Ref. 2.15). Fishing with stationary nets with a mesh size more than 50 mm is also forbidden in the Anapa Bank.

In 2011, the fishing ban was further relaxed to allow trawling of sprat and anchovy in certain areas, with seasonal restrictions to enable the replenishment of fish stocks. The Order of Roslybolovstvo No. 16, issued on 14 January 2011 (Ref. 2.16), specifies periods of the year and the water depths in which trawling for sprat and anchovy is permitted:

\(^{1}\) The continental slope is part of the continental margin, which is the area between the continental shelf and the abyssal plain and comprises a steep continental slope followed by the flatter continental rise.
• For sprat, between 1 July and the 30 September in water depths of more than 40 m; and
• For anchovy, between 1 October and the 15 March in water depths of more than 20 m.

The Ministry of Fisheries administers these restrictions over Russian legal entities, individual entrepreneurs and citizens who practice fishing within the Anapa Bank, and the internal waters of the Russian Federation, through the issuing of fishing permits to all operating fishing vessels. The current boundaries of the Anapa Bank are shown in Figure 2.4.

For Information
2.4.2.3 Relevant Legislation for Permitting

The procedure for obtaining a construction permit is governed by Article 51 of the Town Planning Code of the Russian Federation dated 29 December 2004, No.190-FL (Ref. 2.17).

Once the national EIA has been approved, South Stream Transport will apply for a construction permit which states the conformity of Project documentation with the requirements of the relevant territorial planning system. The construction permit provides the builder with the right to undertake construction, reconstruction of capital development, as well as capital repairs; except for cases stipulated by the Town Planning Code of the Russian Federation.

Offshore construction within the EEZ requires a construction permit issued by a federal executive body. A construction permit within an area which is not subject to town planning regulations or for which urban regulations are not established can be issued by a federal executive body, by an executive authority of the Russian Federation or by a competent local authority.

2.4.2.4 Relevant Legislation for the Offshore Section of the Project

Legislation relevant for the offshore section of the Project includes:

- Russian Federation Law "On Russian Exclusive Economic Zone, Territorial Waters and Adjacent Offshore Areas of the Russian Federation", No. 155-FZ, 31 July 1998 (Ref 2.18);
- Water Code of the Russian Federation No. 74-FZ, 3 June 2006 (Ref. 2.19);
- Russian Federation Law "On the Continental Shelf of the Russian Federation", No. 187-FZ, 30 November 1995 (Ref. 2.20);
- Russian Federation Government Order "On Approval of the Procedure for the Construction of Underwater Cables and Pipelines in the Internal Maritime Waters and Territorial Sea of the Russian Federation", No. 68, 26 January 2000 (Ref. 2.21);
- Russian Federation Government Enactment “On the Adoption of Issuing Permits for Underwater Cabling and Piping on the Continental Shelf", No. 417, 9 June 2010 (Ref. 2.22);
- Russian Federation Government Enactment "On the List of Facilities Subject to Federal Environmental Control", No. 85, 16 February 2008 (Ref. 2.23);
- Russian Federation Law "On State Border of the Russian Federation", No. 4730-1, 1 April 1993 (Ref. 2.24);
- Russian Federation Government Enactment “On Procedure for Adoption of Permissible Standards of Substances and Microorganisms Discharge into Water Bodies for Users of the Water Bodies”, No. 469, 23 July 2007 (Ref. 2.25);
- Russian Federation Government Order “On Adoption the List of Harmful Substances Prohibited to Discharge from Ships and Other Watercrafts, Aircrafts, Artificial Islands, Installations and Structures in the Exclusive Economic Zone of the Russian Federation", No. 251, 24 March 2000 (Ref. 2.26);
2.4.3 EIA and Associated Legislation

The EIA process in the Russian Federation is controlled at the national level by the following laws:

- Article 32 of the Federal Law ‘On Environmental Protection’, No. 7-FZ, 10 January 2002 (Ref. 2.29); and

- ‘Regulations on Environmental Impact Assessment’ sanctioned by the Goskomekologii (the former State Committee for Environment Protection which was responsible for environmental regulation and protection in Russia until it was dissolved in 2000) (Ref. 2.30) of the Russian Federation in Order No. 372 dated 16 May 2000, and registered in the Russian Federation Ministry of Justice, No. 2302, 04 July 2000 (Ref. 2.31).

According to Order No. 372, the Russian Federation EIA process comprises three main stages:

- **Stage 1**: Preliminary Stage, includes notification, pre-assessment to support the development of Terms of Reference (ToR) for EIA, and consultations on the ToR;

- **Stage 2**: EIA Study, includes the development of a Draft EIA Report, disclosure of the Draft EIA to the public for information, and Public Hearings to consult public opinion; and

- **Stage 3**: Finalisation of the EIA Report, taking into consideration the results of public consultation.

The requirements of Order No. 372 are often read in association with the City Planning Code, No. 190-FZ (adopted 29 December 2004) (Ref. 2.17) and with Governmental Order No. 87 (Ref. 2.32) which clarifies the requirements for the Project Design Documentation (the ‘Proekt’).

- Isobaths
Under Russian Federation requirements, the Final EIA Report, the Environmental Protection Measures, and Environmental Monitoring Programme are usually incorporated under Section 7 of the Project Design Documentation for linear facilities. For context, paragraphs 34-42 of Order No. 87 require that Project Design Documentation for linear infrastructure include ten sections:

- Section 1: Explanatory Note;
- Section 2: The Project Right of Way (RoW);
- Section 3: Technological and Design Solutions of Linear Objects and Artificial Structures;
- Section 4: The Buildings, Structures and Facilities that are Included in the Infrastructure of the Linear Object;
- Section 5: Project Construction Management;
- Section 6: Project Organization Demolition (Dismantling) of a Linear Object;
- Section 7: Measures on Environmental Protection;
- Section 8: Fire Safety Measures;
- Section 9: Construction Budget; and
- Section 10: Other Documentation in the Cases Stipulated by Federal Law.

### 2.4.3.1 Russian Authority Review and Approval Process

The main law that prescribes the review and approval process is the Russian Federation Urban Planning Code, No. 190-FL of 29 December 2004 (Ref. 2.17). Law 190-FL requires that Project Design Documentation should pass through State Environmental Expert Review (SEER) and State Expert Review (SER) (Article 49) in cases where the planned activity is within the Continental Shelf, Territorial Sea or EEZ. The requirements for SEER are provided in:

SEER requires, as part of documentation submitted for their review, decision and recommendations of Federal Fisheries Authority (FFA). The requirements for FFA review and approval are provided in Federal law “On Fisheries and the Protection of Water Bio-resources”, No. 166-FZ of 20 December 2004 (Ref. 2.34), and associated Russian Federation Government regulation No. 569 of 28 July 2008 (Ref. 2.35).

In summary, these laws require:

1. Review and approval of fish damage calculations and mitigation measures for aquatic bio-resources by the Federal Fisheries Authority ("Rosrybolovstvo");

---

2. Review and approval of the offshore design documentation by the State Environmental Expert Review (‘Ecologicheskaia Expertiza’); and

3. Review and approval of the whole design documentation by the State Expert Review (‘Glavgosexpertiza’).

The review and approval process takes place consecutively in this order.

2.4.3.2 History of the Project with Reference to National Requirements

With reference to the above legal frameworks, the history of the Project to date can be summarised as follows:

Stage 1: Preliminary Stage of Project Elaboration (Feasibility Study):

- In April 2010, prior to establishment of South Stream Transport A.G. and South Stream Transport B.V., Gazprom submitted a Declaration of Intent for the Project to the Krasnodar Krai Administration;
- On behalf of Gazprom, DIEM prepared a Preliminary EIA as part of a feasibility study that was reviewed and approved by State Environmental Expert Review on 24 September 2010. In summary, SEER concluded that the Feasibility Study and Preliminary EIA complied with regulatory requirements of the Russian Federation; SEER considered the predicted environmental impacts as acceptable; and SEER made recommendations for consideration during the detailed design process and production of the Final EIA Report; and
- South Stream Transport A.G. was then established on 03 October 2011 and became the new proponent of the South Stream Offshore Pipeline.

Stage 2: Development of Project Design Documentation, including EIA according to ToR

During 2012 and 2013, Peter Gaz prepared design documentation for Russian Federation approvals:

- Based on the Preliminary EIA, South Stream Transport prepared a draft ToR for the Project EIA. The ToR was disclosed for public comment in July 2012, and the ToR was finalised in August 2012. The Final ToR for the Project can be found in Russian on the South Stream Transport website at www.south-stream-offshore.com;
- EIA studies were undertaken in accordance with the ToR;
- South Stream Transport moved headquarters from Switzerland to The Netherlands; South Stream Transport B.V. was established on 14 November 2012 and formally became the new proponent of the South Stream Offshore Pipeline;

---

3 Previously, the Project was developed by Gazprom during 2009-2011, and then by South Stream Transport AG during 2011-2012. South Stream Transport then moved its head office from Switzerland to the Netherlands and established South Stream Transport B.V. in November 2012.

4 Note that a Preliminary EIA was not required to be submitted for SEER review and approval by prevailing legislation. It was Gazprom’s voluntary initiative to obtain a preliminary opinion from SEER.
• Sediment dispersion modelling was performed, fish damage calculations prepared, and mitigation measures for aquatic bio-resources were designed in accordance with requirements. The “FFA Package” was submitted to the FFA on 17 April 2013, and was approved by the FFA on 30 May 2013, and by the Azov – Black Sea Territorial Administration (regional branch of FFA) on 16 July 2013; and

• The Draft EIA Report was disclosed for public comment on 29 April 2013, more than 30 days prior to the public hearing that took place in Anapa on 31 May 2013. The public disclosure and public hearing provided opportunities for the public and any non-statutory stakeholders to express their opinions on the Project, and were conducted in conformance with procedures required by Order No. 372.

Stage 3: Finalisation of the EIA Report

• The Offshore EIA was finalised by Peter Gaz in July 2013 taking into consideration the results of public disclosure and hearing. The Onshore EIA was finalised by Peter Gaz in November 2013.

Results of the national EIA, the Environmental Protection Measures, and Environmental Monitoring Programme were incorporated under Section 7 of the Proekt in accordance with Governmental Order No, 87. Project Design Documentation for the marine area (Ref. 2.32), together with FFA approval, was submitted to SEER on 22 July 2013. Approval of the documentation for the offshore component of the Proekt was issued by SEER on 28 October 2013. Project Design Documentation was submitted to SER, in late November to early December 2013. Approval was granted by SER on 13 March 2014.

2.5 Local and Regional Legislation

This section describes the local and regional legislation of relevance to the Project. Key legislation relevant to the Project is described below. A detailed listing of all legislation is included in Appendix 2.2.

2.5.1 Cultural Heritage Sites of Regional Importance

Law No. 313-KZ of the Krasnodar Krai on “Immovable Historical and Cultural Monuments of Historical and Cultural Regional Importance, situated in Krasnodar Krai” dated 17 August 2000 (Ref. 2.36), sets out an approved list of cultural heritage sites located within Krasnodar Krai. These sites are also included in the 'United States Registry of the Cultural Heritage Sites' as sites of regional importance. Law of the Krasnodar Krai No. 2316-KZ dated 19 July 2011 “On the Designated Areas and Protection Zones of Immovable Cultural Heritage (Historical And Cultural Monuments) of Regional and Local Value Located in the Krasnodar Region” (Ref. 2.37) specifies the procedure for changing the protection status of the sites, requirements and limitations of land use associated with the cultural heritage objects, and outlines protection measures including appropriate exclusion zones.
2.5.2 Red Data Book of the Krasnodar Krai

The Decree of the Head of the Administration for Krasnodar Krai, ‘On the Red Data Book of Krasnodar Krai’, dated 21 December 2010 No.1202 (Ref. 2.38), outlines protection principles for the Red Data Book of Krasnodar Krai, as well as the procedure for keeping records and the protection categories of the listed species.

The Krasnodar Red Data Book provides information with regards to the conservation importance or rarity of species, their taxonomy and their distribution. Species listed are assigned a code based on their level of conservation concern and degree of threat. This scale comprises the following categories:

- **Probably Extinct** – Taxa and populations that inhabited Russian territory (or marine area) in the past and whose presence has been not confirmed in 50 years;
- **Endangered** – Taxa and populations whose abundance has decreased down to critical levels so that they can become extinct in the near future;
- **Decreasing Number** – A species identified as being ‘Vulnerable’ is considered to be facing a high risk of extinction in the wild;
- **Rare** – An ‘Endangered’ species that is considered to be facing a very high risk of extinction in the wild;
- **Uncertain Status** – A ‘Critically Endangered’ species that is considered to be facing an extremely high risk of extinction in the wild; and
- **Rehabilitated and Rehabilitating** – Taxa and populations whose number and distribution is recovered or recovering due to the undertaking of protective measures. They are close to the state of stable existence without any urgent measures on protection and rehabilitation.

These categories are aligned with those used by the Red Data Book of the Russian Federation, and are comparable to categories of the IUCN Red List. Chapter 3 Impact Assessment Methodology, Chapter 11 Terrestrial Ecology, and Chapter 12 Marine Ecology describe how these classifications have been used in determining the species sensitivity within the impact assessment process.

2.6 International and Regional Environmental and Social Conventions and Treaties

Russia has ratified international conventions regarding environmental protection, sustainable development, socio-economics and human rights. Table 2.1 outlines the conventions and protocols relevant to the Project.

2.6.1 Espoo Convention

The main objective of the Convention is to promote environmentally sustainable economic development, as a preventive measure against transboundary environmental degradation. The Espoo Convention stipulates obligations of parties to assess transboundary environmental impacts of a project in the early planning stages. It also specifies the obligation of Parties of Origin (parties under whose jurisdiction a planned activity is due to take place) to notify and consult Affected Parties (parties anticipated to be affected by transboundary impacts of a proposed activity) when a project in their territory is likely to have a significant adverse transboundary impact. Parties of origin can ask the developer to undertake further public consultation, in addition to normal EIA requirements.

The Russian Federation signed the Espoo Convention in 1991; however it has yet to be ratified. Nevertheless, in line with IFC Performance Standards, transboundary impacts have been assessed in Chapter 21 Transboundary Impact Assessment.

### 2.6.2 Bucharest Convention

The Convention on the Protection of the Black Sea Against Pollution (Bucharest 1992), also referred to as the Bucharest Convention, was signed and ratified by the Russian Federation, Georgia, Ukraine, Romania, Bulgaria and Turkey.

The basic objective of the Bucharest Convention is to ensure that the contracting parties implement the necessary legislation in order to reduce and control the pollution in the Black Sea and to protect and preserve its marine environment. The Convention also provides a legal framework for co-operation and coordination of the signatory parties.

The Bucharest Convention foresees an obligation on Signatory Parties to assess the impact of and notify the results of this assessment to the Black Sea Commission for any activity under the jurisdiction of that party which may cause substantial pollution or significant and harmful changes to the environment of the Black Sea. Mitigating measures should also be communicated.

South Stream Transport met with the Permanent Secretariat of Black Sea Commission in November 2012 to inform them about the Project and the national EIA and ESIA being undertaken in Russia, Turkey and Bulgaria for the South Stream Offshore Pipeline (further information is provided in Chapter 6 Stakeholder Engagement). It should be noted, however, that the obligation to notify activities that may significantly impact the environment of the Black Sea is the responsibility of the national governments of the respective signatory parties rather than the responsibility of the project owner.

2.7 Standards and Guidelines for International Financing

The Project is being carried out in accordance with applicable standards and guidelines for financing, including the OECD Common Approaches, the Equator Principles III, the Japanese Bank for International Cooperation Guidelines for Confirmation of Environmental and Social Consideration and the International Finance Corporation Performance Standards.

2.7.1 Equator Principles III

The Equator Principles (EP) is a set of ten voluntary environmental and social standards to be adhered to if the Project is to be financed by Equator Principles Financial Institutions (EPFIs). EPFIs are financial service providers that are contracted by a client to carry out banking services for a Project. The Equator Principles were first launched in 2003, subsequently updated in 2006 (EPII) and then again in 2013 (EPIII).

For this Project, EPIII apply. EPIII draw on the 2012 version of the IFC PS and the World Bank Group Environmental, Health and Safety (EHS) Guidelines. The EPs focus on project environmental and social standards and responsibilities. The EPs, in particular, highlight the protection of indigenous peoples, labour standards, and the importance of consultation with locally affected communities. Principles 1 to 6 are most applicable to the ESIA Stage of the Project and have been described below.

2.7.1.1 Principle 1: Review and Categorisation

Principle 1 applies where total Project capital costs are US$10 million or more and includes the steps to be taken by the EPFIs to determine the project category in relation to its potential impacts. Ahead of a formal categorisation by EPFIs South Stream Transport has proceeded with this ESIA process on the assumption that EPFIs will give the Project the categorisation of “A” on the basis that it fits the Category A description: “Projects with potential significant adverse environmental and social risks and/or impacts that are diverse, irreversible or unprecedented.”

2.7.1.2 Principle 2: Environmental and Social Assessment

Principle 2 highlights the need to conduct a Social and Environmental Assessment (e.g. a full-scale ESIA process, a limited or focused audit, or a straightforward application of environmental siting, pollution standards, design criteria, or construction standards depending on the categorisation and likely significance of impacts) to address relevant social and environmental impacts and risks of the Project. The assessment should also propose mitigation and management measures relevant and appropriate to the nature and scale of the Project.

http://www.equator-principles.com/
Given the nature and scale of this Project, a comprehensive ESIA process has been undertaken. Table 2.2 outlines where the ESIA process has addressed the following issues in accordance with Principle 2.

**Table 2.2 Principle 2 Illustrative List of Potential Social and Environmental Issues to be Addressed in the ESIA Report**

**2.7.1.3 Principle 3: Applicable Environmental and Social Standards**

Principle 3 sets out responsibility of an ESIA Report to establish the Project’s overall compliance with (or justified deviation from) the relevant host country laws, respective IFC PS, and EHS Guidelines. The ESIA process has been structured in light of this requirement. Section 2.4.4 and this Section 2.7 provide details of compliance with host country laws, respective IFC PSs and EHS guidelines.

**2.7.1.4 Principle 4: Environmental and Social Management System and Equator Principles Action Plan**

Principle 4 defines the need for Category A (and B) projects to maintain or establish an Environmental and Social Management System (ESMS) which addresses the management of impacts, risks, and corrective actions required to comply with applicable host country social and environmental laws and regulations, and requirements of the applicable IFC PS and EHS guidelines.
Guidelines. Where the applicable standards are not met to the EPFI’s satisfaction, the client and the EPFI will agree an EP Action Plan (AP).

Principle 4 will therefore be addressed through the development and implementation of a Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS), which will be developed in accordance with GIIP and in line with the requirements of ISO 14001:2004 (Environmental Management System) and OHSAS 18001:2007 (Health and Safety Management System). The HSSE-IMS will be developed and refined during the lifetime of the Project. The overall approach to environmental and social management of the Project is summarised in Chapter 22 Environmental and Social Management.

2.7.1.5 Principle 5: Stakeholder Engagement

Principle 5 establishes the requirement to consult with Project Affected Communities in a structured and culturally appropriate manner. For projects with significant adverse impacts on Affected Communities, the client will conduct an Informed Consultation and Participation process and facilitate informed participation by Project Affected Communities to establish whether a project has adequately incorporated their concerns.

The Project has consulted and will continue to consult with relevant stakeholders (people or groups who may be affected by the Project, or who have an interest in it). This engagement to date has included consultation and dialogue about the ESIA process and content, including Project design, expected impacts and measures taken to mitigate and manage impacts.

The South Stream Offshore Pipeline – Russian Sector: Scoping Report (available on the South Stream Transport website) was made publicly available for review on 20 November 2012 for a period of 30 days. During this time, stakeholders had the opportunity to review and comment on the Scoping Report. During this period, South Stream Transport held meetings with a range of stakeholders, including local businesses, local marine users, representatives and general public from affected communities and local, regional and national NGOs.

Further details on consultation and disclosure are included in Chapter 6 Stakeholder Engagement and Chapter 14 Socio-Economics.

2.7.1.6 Principle 6: Grievance Mechanism

Principle 6 sets out responsibility to establish a grievance mechanism as part of the management system that allows the proponent to receive and facilitate concerns and grievances about the Project’s social and environmental performance raised by individuals or groups. The proponent should inform the affected communities about the mechanism in the course of its community engagement process and ensure that the mechanism addresses concerns promptly and transparently, in a culturally appropriate manner, and is readily accessible to all segments of the affected communities.

The requirements for a Grievance Mechanism will be incorporated into the Project HSSE-IMS. As detailed in Chapter 6 Stakeholder Engagement, feedback forms have been used during the Scoping Report consultation process and will continue to be used throughout all Project Stages as part of the on-going stakeholder engagement process. The HSSE-IMS will be developed in accordance with GIIP and in line with the requirements of ISO 14001:2004 (Environmental Management System) and OHSAS 18001:2007 (Health and Safety Management System). The HSSE-IMS will be developed and refined during the lifetime of the Project. The overall approach to environmental and social management of the Project is summarised in Chapter 22 Environmental and Social Management.
Management System) and OHSAS 18001:2007 (Health and Safety Management System). The overall approach to environmental and social management of the Project is summarised in Chapter 22 Environmental and Social Management.

### 2.7.2 OECD Common Approaches, 2012

Governments provide official export credits, through Export Credit Agencies (ECAs), to support national exporters competing for overseas sales. The Common Approaches for Officially Supported Export Credits and Environmental and Social Due Diligence (hereafter referred to as ‘Common Approaches’) recognise that the export credit policy can contribute positively to sustainable development and sets out common approaches for considering environmental and social risks in decisions to offer official support for export credits. The 2012 Common Approaches, as applied to this Project, draw heavily upon the application of recognised international financing institution standards (e.g. EPs and IFC PSs) and apply to all officially supported export credits for capital goods and/or services, excluding military equipment and agricultural commodities.

The Common Approaches objectives are to:

- Promote coherence between members’ policies on officially supported export credits, their international environment, climate change, social and human rights policies, and their commitments under relevant international agreements and conventions;
- Develop common procedures and processes relating to the environment and social aspects for official support of export credits to reduce potential for trade distortion;
- Promote good practice and consistent review and assessment processes to achieve a high level of environmental and social performance as measured against international standards;
- Enhance efficiency of official support procedures and ensure administrative processes are relative to the objectives of the Common Approach; and
- Promote a global level playing field for officially supported export credits and increase awareness and understanding among non-members.

The Russian Federation is one of the many non-member countries with which the OECD has a working relationship, in addition to its member countries. The OECD has been cooperating with the Russian Federation since 1992 and the OECD formally acknowledged in 1997 that the accession of the Russian Federation as a full member of the OECD is the ultimate objective of their cooperation.

To satisfy the requirements of the Common Approaches, South Stream Transport:

- Has commissioned this ESIA Report (prepared to meet international standards including relevant IFC PS);
- Will prevent or mitigate (as far as practicable) adverse environmental and social impacts of the Project;
- Will undertake consultation with relevant stakeholders throughout the life of the Project and encourage transparency through information disclosure; and
• Will implement an HSSE-IMS to monitor and improve performance of the Project in accordance with PS1.

2.7.3 Japan Bank for International Cooperation (JBIC) Environmental Guidelines

The Japan Bank for International Cooperation (JBIC) Guidelines for Confirmation of Environmental and Social Consideration (Ref. 2.4) aims to contribute to efforts towards sustainable development, through consideration of the environmental and social aspects in all projects subject to lending or other financial operations by JBIC and the Nippon Export and Investment Insurance (NEXI).

2.7.4 International Finance Corporation Performance Standards

For this Project the most current 2012 IFC PS will apply. The IFC PSs are voluntary standards that set out underlying principles of sustainable project management, including impact and risk assessment, mitigation strategies, public consultation and performance monitoring. The IFC PSs are mandatory for projects seeking funding from the IFC and are also frequently adopted by other financial institutions, including EPFIs and ECAs. Due to their wide application, South Stream Transport has elected to adhere to 2012 IFC PSs regardless of the source of Project financing.

The PS, their relevance to the Project and a brief description of how they have been addressed in the ESIA process is included below.

2.7.4.1 IFC PS1 Assessment and Management of Environmental and Social Risks and Impacts

PS1 outlines the requirements for social and environmental performance management throughout the life of a project. This is achieved through an integrated assessment to identify the environmental and social impacts, risks, and opportunities of the Project, effective engagement with affected local communities and other stakeholders, and the application of an Environmental and Social Management System (ESMS) to monitor and improve performance.

This PS applies to business activities with environmental and/or social risks and/or impacts. The level of environmental and social assessment and management is expected to be appropriate to the nature and scale of the project. Given the nature and scale of this Project, a comprehensive ESIA process is required to be undertaken, as documented through this ESIA Report. This impact assessment process has taken into consideration the requirements of PS1 through PS8, as well as, the requirements of the Russian Federation (see Section 2.4.4 for details of the Russian EIA Legislation).

As recommended in the IFC's Guidance Notes: Performance Standards on Environmental and Social Sustainability (Ref. 2.7), the following stages have been undertaken as part of this ESIA process:

• **Initial Screening of the Project** – this enabled the identification of Project components and activities; identification of environmental, socio-economic and cultural heritage
receptors; the examination of relevant legislative and lender requirements; and, knowledge of the community values and uses associated with the receptors. An analysis of alternatives was also conducted during this stage to identify and evaluate alternative routes for the offshore pipeline (see Chapter 4 Analysis of Alternatives);

- **Environmental Issues Identification (ENVIID)** – this process enabled the comprehensive identification of the Project’s potential interactions (beneficial and adverse) with environmental, socio-economic and cultural heritage receptors (see Chapter 3 Impact Assessment Methodology);

- **Scoping** – this stage identified the likely significant impacts that require further investigation and defined the final scope of the ESIA process by developing terms of reference for studies to assess Project impacts. Details of the Scoping Stage are reported in the South Stream Offshore Pipeline – Russian Sector: Scoping Report (Ref. 2.78);

- **Stakeholder Engagement** – stakeholder engagement has been undertaken throughout the development of the Project to ensure that all interested parties are aware and informed of the Project and that any potential issues are addressed appropriately (see Chapter 6 Stakeholder Engagement). South Stream Transport has developed a Stakeholder Engagement Plan (SEP) based on the principles and guidance presented in the IFC’s PS1. The SEP also includes engagement activities necessary to meet Russian Federation requirements for the national EIA process. The SEP will be updated periodically throughout the Project lifecycle;

- **Baseline Studies** – the prevailing environmental and social conditions against which the potential impacts of the Project are assessed have been established. This allowed the identification of potentially sensitive receptors (such as ecosystems and local communities) and an evaluation of their level of sensitivity to the impacts. The results are presented on a discipline basis in Chapters 7 to 19 of this ESIA Report; and

- **Impact Significance Assessment** – this was an iterative process considering the following:
  - **Prediction**: What will happen to the environment as a consequence of this Project (i.e. defining Project activities and impacts)?
  - **Evaluation**: Will it have a beneficial or adverse effect? How big is the change expected to be? How important will it be to the affected receptors?
  - **Mitigation**: If the impact is of concern, can anything be done to avoid, minimise, or offset the impact? Or to enhance potential benefits?
  - **Residual Impact**: After mitigation, is the impact still of concern?

  This process is further described in Chapter 3 Impact Assessment Methodology and the results are presented on a discipline basis in Chapters 7 to 19 of this ESIA Report.

- **Cumulative Impact Assessment** – identified the combined effects of the Project with other projects and activities that may, individually or in combination have a significant cumulative impact. Further details regarding the cumulative impacts can be found in Chapter 20 Cumulative Impact Assessment; and

- **Transboundary Impact Assessment** – an assessment was undertaken to identify whether any Project impacts were considered likely to extend across international borders.
(e.g. air or water pollution impacts). Further details regarding the transboundary impacts can be found in **Chapter 21 Transboundary Impact Assessment**.

**Chapter 3 Impact Assessment Methodology** of this ESIA Report provides an overview of the process followed in compiling this ESIA Report and the methodology used to assess impact significance.

Disadvantaged and vulnerable individuals and groups have been identified in accordance with PS1. PS1 states that it is necessary to identify individuals and groups that may be directly and differentially or disproportionately affected by the Project because of their disadvantaged or vulnerable status e.g. by a disability, low income, an existing low level of access to key socio-economic or environmental resources or a low social status which limits their ability to adapt to change. These groups were considered to be a key focus for stakeholder engagement activities undertaken to ensure their concerns about the Project were considered in both Project design and the impact assessment phases. Further assessment and information on disadvantaged and vulnerable individuals and groups is provided in **Chapter 14 Socio-Economics**.

PS1 also stipulates that the Project proponent develop a formal environmental and social policy that reflects the principles captured in the PSs. The South Stream Transport Sustainability Policy is outlined in Section 2.2 and an HSSE-IMS is being developed in accordance with GIIP and in line with the requirements of ISO 14001:2004 (Environmental Management Systems) and OHSAS 18001:2007 (Health and Safety Management Systems). The overall approach to environmental and social management of the Project is summarised in **Chapter 22 Environmental and Social Management**.

**2.7.4.2 IFC PS2: Labour and Working Conditions**

PS2 establishes the need for workers’ rights regarding income generation, employment creation, relationship management, commitment to staff, retention and staff benefits. It identifies and outlines the need to provide workers with a safe and healthy working environment. This PS is guided by international conventions, in particular those of the International Labour Organisation (ILO). Ultimately, the scope of application of this PS depends on the type of employment relationship between the Project and the worker e.g. it applies to workers directly engaged by the client (direct workers), as well as, workers engaged through third parties.

It is recognized that up to approximately 1,200 workers (including all sub-contracted parties and workers) may be engaged at any one time for the Project and, as such, compliance with PS2 is considered to be of relevance to the Project. Worker rights will be consistent with those of South Stream Transport, which is firmly committed to the protection of worker rights in compliance with the conventions listed in Table 2.1 and the relevant Russian statutory requirements.

In particular, the offshore pipelay works will utilise a large workforce (e.g. some vessels may contain over 700 workers at any one time). South Stream Transport is cognisant of the potential labour and working condition risks associated with confined employment and shift work conditions associated with offshore vessel operations. As part of the Project HSSE-IMS, regular audits of working conditions upon these vessels shall be undertaken.
Implementation of the necessary actions required by this PS will be managed through the Project ESMS. Further details on labour and working conditions, as well as occupational health, is included within Chapter 14 Socio-Economics. The overall approach to environmental and social management of the Project is summarised in Chapter 22 Environmental and Social Management.

2.7.4.3 IFC PS 3: Resource Efficiency and Pollution Prevention

PS3 defines an approach to pollution prevention and abatement in line with current internationally available technologies and good practice. It deals with ambient and cumulative considerations, resource conservation and energy efficiency, hazardous materials and waste management, pesticide use and management, and emergency preparedness and response provisions.

The Project will utilise resources which have the potential to generate pollution. The majority of resources that will be used and potential pollution events (e.g. waste spillage, noise, air pollutants, and greenhouse gases) will arise through the Project’s Construction Phase. The main resource used during the Construction Phase will be steel for the pipeline. Throughout the Project Development Phase, efficiency of resource use has been considered and a range of minimum performance criteria and standards have been adopted. Chapter 5 Project Description details the range of design, construction and operational standards adopted for the Project.

For both the construction and operation phases, specific mitigation measures (encompassing both avoidance and minimisation measures) to address Project emissions (e.g. emissions associated with exhaust fumes of vessels) are described in the relevant technical chapters of this ESIA Report. In particular, Project resource efficiency measures are included in Chapter 5 Project Description and Project-related greenhouse gas (GHG) emissions are considered within Chapter 9 Air Quality.

In terms of waste, Chapter 18 Waste Management of this ESIA Report details how wastes will be managed throughout the Project, taking into consideration the need for resource use efficiencies. Specifically, the Project will adopt a waste management hierarchy. The waste hierarchy ranks waste management options according to what is best for the environment. In particular, the prevention, re-use and recycling of Project items where possible will help maximize resource use efficiency throughout the Project.

The overall approach to environmental management in line with these guidelines is summarised in Chapter 22 Environmental and Social Management.

2.7.4.4 IFC PS 4: Community Health, Safety and Security

PS4 outlines specific requirements for mitigating any potential for community exposure to risks and impacts arising from equipment and infrastructure accidents, releases of hazardous materials and communicable diseases.

The ESIA process has included extensive data gathering on the communities’ social, economic and health conditions (as detailed in Chapter 14 Socio-Economics of this ESIA Report) as well as data on crime rates.
Project activities have been analysed to determine which aspects associated with the construction and operational phases of the Project could adversely impact communities.

Community health impacts have, for example, been assessed in relation to air emissions from the Project site, noise disturbance and interaction of communities with a large number of migrant workers.

Safety issues have been addressed both in relation to indirect hazards associated with the Project Construction Phase (increased traffic, presence of heavy machinery) and to the safety of the pipeline itself. Major Accident Hazards (MAHs) in relation to the local community during construction, installation and operation of the pipelines are addressed in Chapter 19 Unplanned Events. Detailed plans for dealing with the effects on the community of construction, installation and operation of the pipelines will be prepared and managed by South Stream Transport and the respective contractors through South Stream Transport’s HSSE-IMS.

Security issues have been analysed in the context of the temporary interaction of relatively small rural communities with a large construction workforce.

2.7.4.5 IFC PS 5: Land Acquisition and Involuntary Resettlement

PS5 recognises that Project related land acquisition and restrictions could have adverse effects on communities or persons that use the land, and therefore, PS5 outlines objectives for avoiding or minimising involuntary physical resettlement as a consequence of development. Appropriate measures should be implemented to mitigate adverse impacts on displaced persons and host communities through appropriate compensation for resettlement or any economic displacement, such as loss of subsistence or commercial livelihood.

The Project will require either the acquisition of land or the leasing of land off of current owners for the onshore pipeline and landfall facilities. The potential impacts of the acquisition and leasing of land for the onshore pipeline and landfall facilities are addressed in Chapter 14 Socio-Economics.

No physical resettlement is anticipated; therefore, no Resettlement Action Plan is required.

2.7.4.6 IFC PS 6: Biodiversity Conservation and Sustainable Management of Living Natural Resources

PS6 sets out an approach to protect and conserve biodiversity, including habitats, species and communities, ecosystem diversity, and genes and genomes, all of which have potential social, economic, cultural and scientific importance. It also sets out definitions of natural, modified and critical habitat types, stating that there should be no net loss of critical habitat as a result of the Project.

The Project has the potential to directly and indirectly impact natural and modified habitat types, both onshore and offshore (e.g. direct loss of habitat, temporary degradation of habitat, injury / harm to species etc.). These impacts have been assessed where necessary according to IFC Guidance for critical habitats. The potential impacts on marine and terrestrial ecology and the relevant identified mitigation measures to address these impacts are detailed in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology.
The Project may affect potential beneficiaries who may currently benefit from some ecosystem services. A discussion of the ecosystem services received and potential Project impacts upon these services is provided in Chapter 14 Socio-Economics of this ESIA Report and fully detailed in Chapter 17 Ecosystem Services.

2.7.4.7 IFC PS 7: Indigenous Peoples

PS7 recognises that indigenous peoples can be marginalised and vulnerable if their lands and resources are encroached upon by or significantly degraded by a Project. It recognises that their languages, cultures, religions, spiritual beliefs, and institutions may also be under threat.

Within PS7 the term ‘Indigenous Peoples’ is used in a generic sense to refer to a distinct social and cultural group possessing the following characteristics in varying degrees:

- 'Self-identification as members of a distinct indigenous cultural group and recognition of this identity by others;
- Collective attachment to geographically distinct habitats or ancestral territories in the project area and to the natural resources in these habitats and territories;
- Customary cultural, economic, social, or political institutions that are separate from those of the mainstream society or culture; or
- A distinct language or dialect, often different from the official language or languages of the country or region in which they reside.'

The ethnical breakdown of the communities within the surrounding population of the Project has been studied along with the level of interaction and their cultural customs. Further information on these studies is detailed within Chapter 14 Socio-Economics. No truly indigenous communities will be affected by the Project, and PS7 is not considered directly applicable. However, pockets of minority nationals exist near Anapa (the strong Armenian community), and some of the principles of PS7 have been applied in regards to this community (see Chapter 14 Socio-Economics).

2.7.4.8 IFC PS 8: Cultural Heritage

PS8 aims to protect irreplaceable cultural heritage and to provide guidance for protecting cultural heritage throughout a project’s lifecycle. PS8 states that for the purposes of this PS, cultural heritage refers to tangible forms of cultural heritage (e.g. property, sites, structures, or groups of structures with archaeological (prehistoric), paleontological, historical, cultural, artistic, and religious value), unique natural features or tangible objects that embody cultural values (e.g. sacred groves, rocks, lakes, and waterfalls), and certain instances of intangible forms of culture that are proposed to be used for commercial purposes (e.g. cultural knowledge, innovations, and practices of communities embodying traditional lifestyles).

A number of tangible cultural heritage receptors are currently known to be present within the landfall study area and it is therefore considered highly likely that additional objects of archaeological significance could be unearthed during onshore construction activities. Similarly, a number of confirmed cultural heritage objects have been identified offshore (including a shipwreck and a World War II airplane wing) and several potential objects have been identified.
through preliminary marine surveys. A full description of all identified cultural heritage items and places of significance is provided in Chapter 16 Cultural Heritage.

Impacts on onshore cultural heritage and archaeological objects may arise as a result of direct physical disturbance from construction activities (e.g. vegetation clearance, excavation works and pipeline laying). The significance of these impacts and corresponding mitigation measures to avoid and reduce the scale of impacts are discussed in Chapter 16 Cultural Heritage.

It is not anticipated that the Project will have an impact on intangible cultural heritage due to the location of the landfall section in areas with no specific notable or listed cultural traditions that could be affected by the Project. Nevertheless, potential impacts on the living cultural heritage and religious practices of communities are considered as part of this ESIA Report. Further details on both tangible and intangible cultural heritage receptors and the potential impacts associated with the Project are included in Chapter 16 Cultural Heritage.

3 Impact Assessment Methodology

3.1 Introduction

The impact assessment methodology used in this ESIA Report provides a basis to characterise the potential environmental and social impacts of the Project. The methodology is based on models commonly employed in impact assessment, and takes into consideration the International Finance Corporation (IFC) Performance Standards (PS).

Potential impacts arising from planned activities and unplanned events are assessed. Planned activities include routine and non-routine Project activities or events required for the Construction and Pre-Commissioning, Operational, or Decommissioning Phases of the Project; for example, the planned activity of pipe-laying might disrupt seabed sediments leading to an increase in water turbidity. Unplanned events are those not anticipated to occur during the normal course of Project activities; for example, the unlikely event of a vessel collision that may lead to a spill of fuel.

The impact assessment methodology for planned activities takes into consideration impact magnitude and receptor sensitivity. A matrix is also used to derive impact significance, for pre- and post-mitigation conditions.

The concept of likelihood is included in the methodology for unplanned events. The likelihood of the event occurring, and the likelihood of impacts arising are considered.

The assessment of discipline-specific impacts is presented in Chapters 8 to 18. Unplanned Events are addressed in Chapter 19 Unplanned Events, and Cumulative and Transboundary impacts are assessed in Chapters 20 Cumulative Impact Assessment and Chapter 21 Transboundary Impact Assessment respectively.

3.2 ESIA Process

The ESIA process is a systematic approach to identifying the environmental and social impacts of a project, and describing the mitigation, management and monitoring measures that will be implemented to address these impacts. Ultimately, it allows relevant organisations to make informed decisions about development proposals, and allows potentially affected stakeholders to participate in the process.

In order to ensure a robust and detailed impact assessment, the ESIA process has been structured over a series of progressive and iterative stages (Figure 3.1). Stakeholders, the Project team, and assessment team provided input to these stages during the ESIA process.

As part of the Project design process, measures to avoid or minimise impacts were identified and incorporated into the design. These are referred to as “design controls” and include physical design features and management measures. These design controls considered the IFC mitigation hierarchy as discussed in PS1. Section 3.3.10 of this report discusses this hierarchy and how it was applied to the Project’s impact assessment in more detail. They are based on Good International Industry Practice (GIIP) and are intended to assist in the avoidance and
control of unacceptable impacts. Specific design controls are described in greater detail in Chapter 5 Project Description. Where the outcome of the ESIA indicates that design controls are insufficient to manage an impact to an acceptable level, further measures have been identified. These measures have been termed “mitigation measures” and are described in respective chapters and detailed in Environmental and Social Management Plans (Chapter 22 Environmental and Social Management).

As shown in Figure 3.1, the ESIA process comprised the following stages:

- **Screening**: an initial identification of potential interactions between the Project and physical, ecological and human receptors (Section 3.2.1) indicating the level of impact assessment required;

- **ESIA Scoping**: outlines the perceived required scope of the ESIA to be undertaken, taking into consideration the nature of the Project, the results of the screening and applicable requirements. This stage included:
  - Environmental Issues Identification (ENVIID): a process of systematic identification of potential interactions between Project activities / events and known receptors (Section 3.2.2.1);
  - Desk-based studies: a review of existing environmental and social information, and gap analysis to identify additional baseline information required for the impact assessment. This included review of previous environmental and geotechnical survey data collected by Peter Gaz on behalf of Gazprom between 2008 and 2012 (Section 3.2.2.1);
  - Identification of potential physical, ecological, and human receptors that may be affected by the Project (Section 3.2.2.3);
  - Alternatives: assessment of Project technical alternatives at the Scoping Stage, including alternative routes and methods (Section 3.2.2.4); and
  - Stakeholder engagement: in November 2012, the South Stream Offshore Pipeline – Russian Sector: Scoping Report was published by South Stream Transport on the company website. Copies were also made available in local communities, and provided directly to some stakeholders. Interested and affected parties were invited through advertisement and direct invitation to participate in scoping meetings, held in Anapa and in Moscow during the week of 10-14 December 2012 (see Chapter 6 Stakeholder Engagement for further details). Feedback from the scoping meetings was taken into consideration in the ESIA process.

- **Baseline field surveys**: Following a gap analysis undertaken as part of the ESIA Scoping Stage, baseline field surveys were undertaken to complement existing information. The baseline environmental and social conditions against which the impact assessment was to be undertaken (Section 3.2.3) were described;

- **Impact assessment**: This stage included:
  - Building on the ENVIID conducted during the Scoping Stage to describe activities and potential impacts (Section 3.3.1);
  - Determining the nature of impact (Section 3.3.2), the expected magnitude of impact (section 3.3.3) and the sensitivity of receptors (Section 3.3.4);
  - Assessing the significance of potential impacts (Section 3.3.5) prior to planned mitigation;
Considering unplanned events, i.e. those events which are not expected to happen during the Project but for which the risk of the event occurrence needs to be assessed (Section 3.3.6); Considering the potential for Project impacts to combine with other impacts associated with existing or planned developments (cumulative impacts, Section 3.3.7) and the potential for Project impacts to extend across national boundaries (transboundary impacts, Section 3.3.8); and Assessing the significance of residual impacts (section 3.3.10) taking into consideration proposed mitigation measures (Section 3.3.9).

- **Environmental and Social Management Plan**: This stage included the development of management plans and procedures as part of South Stream Transport’s Health, Safety, Security and Environment Integrated Management System (HSSE-IMS), which captures all of the mitigation measures identified so that they can be practically applied as part of Project development (Section 3.3.11);
- **Stakeholder engagement**: Consultation with regulators and other stakeholders regarding the scope and content of the ESIA Report as well as aiding in the identification of potential Project impacts. Stakeholder engagement has and continues to run across the entire ESIA process (Section 3.4); and
- **ESIA report disclosure**: Release of the ESIA Report to the public so that they can provide opinion and comment on the report or the planned environmental and social management of the Project.

The process is summarised in Figure 3.1, and is described in further detail in following subsections.

### 3.2.1 Screening

Screening¹ was the first stage undertaken during the ESIA process to identify potential interactions between the Project and existing physical, ecological, and human receptors. Undertaking screening early in the ESIA process facilitated the incorporation of environmental and social considerations into the development of the Project design.

The Screening Stage included the following key steps:

- Identification of Project components and activities;
- Identification of likely physical, ecological and human receptors based on existing knowledge of the environmental and social baseline conditions and professional expertise;
- Examination of relevant national and international legislative requirements; and
- Development of a screening matrix to illustrate the potential interactions of Project activities with the physical, ecological and human receptors.

---

¹ Screening in the context of this section refers to early stage of scoping prior to the preparation of the Scoping Report (Ref 3.1).
Decommissioning activities were not considered in detail during the Screening Stage due to limited information available at that time. The resultant screening matrix is presented in Table 3.1.

### Chapter 3 Impact Assessment Methodology

#### 3.2.2 ESIA Scoping

Following the Screening Stage, scoping was undertaken to provide further detail of potential environmental and social effects of the Project using additional engineering and baseline data. The Scoping Stage intended to facilitate impact identification in a consistent and robust manner.

#### 3.2.2.1 Environmental Issues Identification (ENVIID) Register

Scoping included a systematic consideration of Project activities and their potential impact on physical, ecological and human receptors. An ENVIID was conducted to determine activities, receptors and impacts of all phases of the Project. This process, supported by interdisciplinary workshops (attended by Project engineers and environmental and social scientists), enabled a comprehensive identification of the Project's potential interactions (beneficial and adverse) with physical, ecological and human receptors. This information was recorded in an ENVIID Register that provided a reference for potential impacts requiring further investigation during the ESIA process.

#### 3.2.2.2 Desk-Based Studies – Review of Existing Baseline Information

An important component of the Scoping Stage is the definition of existing baseline conditions (i.e. the prevailing environmental and social characteristics against which the potential impacts of the Project can be assessed). Baseline conditions were defined during the Scoping Stage through a review of existing environmental and social information.

A significant body of information was available in environmental and geotechnical survey data and reports prepared for the Project between 2008 and 2012 (Ref. 3.2). This information included the results of terrestrial and marine ecology, water quality, sediment and geology, soil and groundwater, cultural heritage and contamination surveys undertaken within the Project Area of Influence.

In addition to Project-specific information, scientific journals, reports by government agencies and by other groups, were reviewed for relevant baseline information.

Existing baseline information used for ESIA Scoping Stage also formed the core of baseline information in the impact assessment (Section 3.3). Where gaps were identified between baseline information available at the Scoping Stage and that required for the ESIA Report (e.g.
out of date, too narrow in scope, etc.), additional surveys or studies were undertaken to collect the required information.

3.2.2.3 Identifying Receptors

Receptors are environmental components, people and cultural heritage assets that may be affected, adversely or beneficially, by the Project. Potential receptors were identified through both desk and field-based studies, taking into consideration likely Project impacts. Based on the review of existing information, four high-level categories of Project receptors were identified:

- Physical (i.e. non-living environmental components, including air quality, water bodies, landscapes, terrestrial soils, marine sediments and geology);
- Marine ecology (i.e. marine habitat, flora and fauna);
- Terrestrial ecology (i.e. terrestrial habitat, flora and fauna); and
- Human (i.e. landowners and residents of local communities, local economy, marine users, cultural heritage).

Individual receptors within these groups were assessed as part of the impact assessment (Chapters 8 to 18) for their sensitivity to the potential impacts of the Project. Human receptors identified formed the basis of the stakeholder engagement activities undertaken (Section 3.4).

3.2.2.4 Analysis of Alternatives

An analysis was undertaken of technically and financially feasible alternatives that would allow the development of a new supply route that provides a safe and reliable means to export Russian gas to the countries of Central and South-Eastern Europe via the Black Sea.

The presentation of the Analysis of Alternatives followed a ‘narrowing approach’ involving a series of logical steps, starting with the high-level alternatives and progressively narrowing-in on more detailed alternatives. Using this commonly adopted approach the Analysis of Alternatives considers each of the following in series:

- South Stream Offshore Pipeline alternatives:
  - Alternative means of gas transportation; and
  - Offshore (macro) routing.
- The ‘Zero’ or ‘No Project’ alternative;
- Project alternatives:
  - Landfall site selection;
  - Shoreline crossing technique (open cut vs. microtunnelling);
  - Onshore routing; and
  - The offshore route optimisation.

The Analysis of Alternatives is described in Chapter 4 Analysis of Alternatives. Alternative mitigation and monitoring measures were also considered in the course of the assessment.
3.2.3 Additional Baseline Field Surveys and Studies

Field surveys and desk-based studies required to address identified gaps in baseline data were carried out during 2012 to 2013, and included:

- Air quality monitoring;
- Noise monitoring;
- Terrestrial ecology field surveys (habitat and species based surveys);
- Marine ecology surveys (habitat and species based surveys);
- Marine sediments and sea water quality sampling;
- Cultural heritage identification surveys;
- Beach-use surveys;
- Road traffic surveys; and
- Landscape and visual amenity characterisations.

The details of the surveys undertaken (timing, location, methods and results), together with information gathered through the desk-based studies, are presented in the relevant chapters of this ESIA Report.

3.3 Impact Assessment Framework

The process for assessing potential Project impacts is illustrated in Figure 3.2 and involved:

- **Prediction**: What will happen to the environment as a consequence of this Project (i.e. defining Project activities and impacts)?
- **Evaluation**: Will it have a beneficial or adverse effect? How big is the change expected to be? How important will it be to the affected receptors?
- **Mitigation**: If the impact is of concern, can anything be done to avoid, minimise, or offset the impact? Or to enhance potential benefits?
- **Residual Impact**: After mitigation, is the impact still of concern?

Impact significance was assessed with and without mitigation measures in place. The impact significance without mitigation measures was assessed with the design controls in place (Section 3.2). Impacts without mitigation measures in place are not representative of the Project’s actual extent of impact, and are included to facilitate understanding of how and why mitigation measures were identified.

The residual impact is what remains following the application of mitigation and management measures, and is thus the final level of impact associated with the development of the Project. Residual impacts also serve as the focus of management and monitoring activities during Project implementation to verify that actual impacts are the same as those predicted in this ESIA Report.
For some types of impact, there are empirical, objective and established criteria for determining the potential impact significance (e.g. if a standard is breached or a protected area is damaged). However, in other cases assessment criteria are more subjective and require professional judgement to a greater degree. The criteria against which the significance of planned impacts was evaluated, for the purposes of this Project, has been described in terms of two components: impact magnitude (Section 3.3.3) and receptor sensitivity (Section 3.3.4). The assessment of unplanned impacts is described in Section 3.3.6.

Figure 3.2 Impact Identification and Assessment Process

3.3.1 Activities and Impacts

Building upon the ENVIID conducted during the Scoping Stage, Project activities and potential impacts upon physical, ecological and human receptors were further defined. For this purpose, the definition of a Project impact was adapted from ISO 14001:2004 (Ref 3.3) as:

- "Any change to the environment [or social receptors], whether adverse or beneficial, wholly or partially resulting from an organization’s environmental [or social] aspects."

Definitions of an ‘activity’ and a ‘receptor’ are not included within ISO 14001:2004, but for the purposes of this Project the following definitions are provided.

---

2 Although not designed specifically for use in impact assessment certain terms and principles of this standard were adopted to assist with the impact identification / Scoping Stage.
A Project activity is considered to be:

- A physical action or presence of infrastructure associated with the operation of Project plant, equipment or vehicles, or the actions of Project employees.

A Project receptor is considered to be:

- Someone or something that could be influenced by the Project, including human health, water resources, air quality, ecological habitats or species, cultural heritage assets, and the wider environment.

An impact therefore represents the effect of an interaction of a Project activity with the physical, ecological and human receptor. Two examples of these relationships are provided in Figure 3.3.

**Figure 3.3 Examples of Project Activity - Impact Pathways**

<table>
<thead>
<tr>

<td>RECEPTOR</td>
<td>Air quality and climate</td>
<td>Seawater quality</td>
</tr>
<tr>
<td>IMPACT</td>
<td>Deterioration of air quality, global warming</td>
<td>Environmental degradation, economic losses</td>
</tr>
</tbody>
</table>

Project activities were identified through a review of the Project Description (Chapter 5). Potential impacts were identified based on the details of Project activities and their potential interactions with the surrounding environment (and physical, ecological, and/or human receptors). This also required an understanding of the potential sources of impacts and impact pathways, and was supported by:

- An understanding of baseline conditions and potential receptors (Chapters 8 to 18);
- Spatial and temporal extent of the Project Area of Influence (Chapter 1);
- Information from stakeholders, including authorities, experts, and the public (Chapter 6); and
- Professional knowledge and experience of comparable projects or developments.
To some extent, the identification and understanding of Project activities and impacts was an iterative process conducted throughout the ESIA process as more Project and environmental and social baseline information became available.

The assessment of these environmental and social impacts has been structured according to the following technical disciplines:

- Terrestrial soil, water, and groundwater (Chapter 8);
- Air quality (Chapter 9);
- Terrestrial noise and vibration (Chapter 10);
- Terrestrial ecology (Chapter 11);
- Marine ecology (Chapter 12);
- Landscape and visual (Chapter 13);
- Socio-economics (Chapter 14);
- Community Health, Safety and Security (Chapter 15);
- Cultural heritage (Chapter 16);
- Ecosystem services (Chapter 17); and
- Waste (Chapter 18).

### 3.3.2 Impacts Nature and Type

Whether an impact is considered to be beneficial or adverse (impact nature), and the way in which it is related to the Project (impact type, e.g. direct, indirect) are relevant to the ESIA process. In particular, the degree to which an impact may be managed or modified by the mitigation measures is dependent upon the impact nature and type. Table 3.2 provides definitions.

**Table 3.2 Impact Assessment Terminology**

<table>

### Impact Type

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct Impact</td>
<td>Impacts that result from a direct interaction between a Project activity and the receiving environment (e.g. between occupation of an area of seabed and the habitats which are lost).</td>
</tr>
<tr>
<td>Indirect Impact</td>
<td>Impacts that result from other activities that are encouraged to happen as a consequence of the Project (e.g. Project implementation promotes service industries in the region).</td>
</tr>
<tr>
<td>Secondary Impact</td>
<td>Impacts that follow on from the primary interactions between the Project and its environment as a result of subsequent interactions within the environment (e.g. loss of part of a habitat affects the viability of a species population over a wider area).</td>
</tr>
<tr>
<td>Cumulative Impact</td>
<td>Impacts that act together with other impacts, from other projects or unrelated activities, to affect the same environmental resource or receptor.</td>
</tr>
</tbody>
</table>

In considering impacts related to this Project, both adverse and beneficial impacts have been identified. Where appropriate, the impact assessment chapters further identify impacts as direct, indirect or secondary impacts. Where appropriate, both impact nature and type definitions have been applied throughout the ESIA Report to provide clarity regarding the significance of the impacts. Cumulative impacts are discussed in Section 3.3.8 and Chapter 20 Cumulative Impact Assessment.

### 3.3.3 Impact Magnitude

The magnitude of an impact is a measure of change from baseline conditions. This measure of change can be described in terms of its:

- **Extent:** Spatial extent (e.g. area impacted) or population extent (e.g. proportion of the population / community affected) of an impact;
- **Duration:** How long the impact will interact with the receiving environment;
- **Frequency:** How often the impact will occur; and
- **Reversibility:** How long before impacts on receptors cease to be evident.

Thus, these characteristics collectively describe the nature, physical extent, and temporal condition of the impact.

To facilitate a structured description of impact magnitude, a qualitative category scale of negligible, low, moderate, and high was developed for each of the magnitude characteristics.
Criteria for each impact magnitude category (i.e. negligible, low, moderate and high ranking criteria) were developed as appropriate for each discipline, and are described in Chapters 8 to 18.

The determination of overall impact magnitude rating was determined on the basis of professional judgement and Good International Industry Practice (GIIP), considering all four characteristics collectively where relevant.

### 3.3.4 Receptor Sensitivity (Resilience and Value)

Receptor sensitivity is the degree to which a particular receptor is more or less susceptible to a given impact. Receptor sensitivity takes into consideration receptor resilience and value.

Receptor resilience (or conversely, vulnerability) describes the ability of the receptor to withstand adverse impacts. It takes into consideration not only activity-impact-receptor pathways, but also environmental characteristics of the receptor that might make it more or less resilient to change. As such, a receptor can be considered as existing within a spectrum of ‘vulnerable’ to ‘resilient’, with the former more likely to experience significant impacts as a result of a given change.

Receptor value takes into consideration its quality and its importance as represented, for example, by its conservation status, its cultural importance and / or its economic value. It recognises that, for a given magnitude impact, different receptors (either directly or indirectly) may be deemed to be of greater importance and as such the significance of the impact is greater than the impact magnitude alone.

Similar to the approach adopted for impact magnitude, a structured description of receptor sensitivity employed a qualitative category scale of negligible, low, moderate, and high for each of the sensitivity characteristics, resilience and value. Likewise, criteria for receptor sensitivity (i.e. negligible, low, moderate and high ranking criteria) were developed as appropriate for each discipline, and are described in Chapters 8 to 18.

### 3.3.5 Impact Significance

Impact magnitude and receptor sensitivity were used to assess impact significance according to the impact assessment matrix in Table 3.3, and the impact assessment definitions in Table 3.4.

Table 3.4 Impact Significance Definitions

<table>
<thead>
<tr>
<th>Adverse Impacts</th>
<th>High</th>
<th>Moderate</th>
<th>Low</th>
<th>Not Significant</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Significant.</strong></td>
<td>Impacts with a &quot;High&quot; significance are likely to disrupt the function and value of the resource / receptor, and may have broader systemic consequences (e.g. ecosystem or social well-being). These impacts are a priority for mitigation in order to avoid or reduce the significance of the impact.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Significant.</strong></td>
<td>Impacts with a &quot;Moderate&quot; significance are likely to be noticeable and result in lasting changes to baseline conditions, which may cause hardship to or degradation of the resource / receptor, although the overall function and value of the resource / receptor is not disrupted. These impacts are a priority for mitigation in order to avoid or reduce the significance of the impact.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Detectable but not significant.</strong></td>
<td>Impacts with a &quot;Low&quot; significance are expected to be noticeable changes to baseline conditions, beyond natural variation, but are not expected to cause hardship, degradation, or impair the function and value of the resource / receptor. However, these impacts warrant the attention of decision-makers, and should be avoided or mitigated where practicable.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Not Significant.</strong></td>
<td>Any impacts are expected to be indistinguishable from the baseline or within the natural level of variation. These impacts do not require mitigation and are not a concern of the decision-making process.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The above matrix and significance definitions have been used to assess adverse impacts of the Project. Although beneficial impacts of the Project are identified within this ESIA, beneficial impacts have not been assessed in terms of receptor sensitivity or impact magnitude. Rather, beneficial impacts have been described in qualitative terms and measures presented that South Stream Transport and other parties, where indicated, will employ to maximise benefits.
For adverse impacts, this methodology was applied to both pre- and post-mitigation scenarios for all impacts identified. The reasoning behind each evaluation is explained in the Chapters 8-18, depending on the relevant discipline, including a detailed discussion of the issues contributing to the determination of residual significance.

The impact assessment in each technical chapter includes an impact summary table for each phase of the Project (an example is presented in Table 3.5), including residual impact significance ratings for all impacts identified.

### 3.3.6 Waste

In contrast to the other environmental and social technical disciplines assessed within this ESIA, no pre-mitigation assessment of impact was undertaken for waste production, storage, management and disposal as this is considered part of the Project design as described in Chapter 5 Project Description. Rather, Chapter 18 Waste Management focuses upon identification of appropriate mitigation measures given the type and volume of wastes to be produced and identification of residual impact significance ratings. This methodology is described in further detail in Chapter 18 Waste Management.

### 3.3.7 Unplanned Events

Environmental and social impacts that might result from unplanned events (e.g. fuel spill, or wet buckle) are addressed in Chapter 19 Unplanned Events. In addition to impact magnitude and receptor sensitivity, the impact assessment methodology for unplanned events also considered the likelihood of occurrence of the event(s). This methodology is described in further detail in Chapter 19 Unplanned Events.

### 3.3.8 Cumulative Impacts

This ESIA adopts the IFC definition of cumulative impacts (Ref. 3.4): "Cumulative impacts are those that result from the incremental impact of the Project when added to other existing, planned and reasonably predictable future projects and developments."

The IFC has released a guidance note Cumulative Impact Assessment and Management – Guidance for the Private Sector in Emerging Markets in August 2013 (Ref. 3.5). The guidance note introduces a framework for identifying and assessing potentially significant cumulative impacts. The cumulative impact assessment (CIA) has been prepared taking into account the IFC draft guidance note.

A predominantly qualitative approach was taken in the identification and assessment of cumulative impacts during the construction and operations phases of the Project, taking into account geographic and scheduling overlaps with the Project. The methodology for the CIA is described in further detail in Chapter 20 Cumulative Impact Assessment.

3.3.9 Transboundary Impacts

Transboundary impacts are defined as “impacts that extend to multiple countries, beyond the host country of the project, but are not global in nature. Examples include air pollution extending to multiple countries, use or pollution of international waterways, and transboundary epidemic disease transmission” (Ref. 3.4).

As the South Stream Offshore Pipeline spans multiple countries and is being constructed across a dynamic marine environment, there is the potential for some Project activities to generate transboundary impacts. Such impacts may arise from Project activities which traverse country boundaries, or impacts that originate within one country, but have the ability to extend across national borders.

For the purposes of the transboundary impact assessment included within this ESIA, the Russian national borders and the boundary of the Russian EEZ in the Black Sea define the transboundary impact boundaries. Any changes in baseline conditions extending across these boundaries would be considered to be a transboundary impact.

IFC Performance Standard (PS) 1 Assessment and Management of Environmental and Social Risks and Impacts (Ref. 3.6) recognises the need to consider transboundary impacts. The transboundary impact assessment (Chapter 21) has considered the potential for transboundary impacts to be generated by the Project as required by IFC PS1 Further details regarding potential transboundary impacts can be found in Chapter 21 Transboundary Impact Assessment.

3.3.10 Impact Mitigation

As part of the ESIA process, where the impact assessment identified impacts as potentially arising, mitigation measures were developed (including avoiding, management and monitoring actions). Where an adverse impact is identified, the next step is to find a way to avoid or minimise the impact. The process of identifying “design controls” and “mitigation measures” considered the mitigation hierarchy (Figure 3.4), as specified in IFC PS1, which is widely regarded as a best practise approach to managing risks.

For the Project, efforts were made to firstly avoid or prevent, then minimise or reduce adverse impacts, which were principally achieved through the application of “design controls” (Section 3.2). Avoidance, minimisation repair and/or restoration were considered during the application of “mitigation measures” to manage the risks of adverse impacts. Any remaining significant residual impacts were then addressed via consideration of measures including offsetting and compensation.

For biodiversity, the same hierarchy was applied to all stages of the impact assessment process, in order to achieve “no net loss” of biodiversity. The assessment of critical habitat for biodiversity was identified separately to the above impact assessment process, albeit using the same hierarchy, to achieve “net gain” of the biodiversity values for which the critical habitat was designated.

The mitigation hierarchy adopted for the Project is shown in Figure 3.4.
This process involved ESIA experts working with the Project team engineers to identify practicable and cost-effective approaches to mitigate impacts. These measures were agreed and integrated into the Project plan.

Specific mitigation measures are described in the relevant discipline chapters (Chapters 8 to 18).

**Figure 3.4 Mitigation Hierarchy**

- **Avoid**
  - Make changes so that the impact is avoided altogether.
- **Minimise**
  - Apply measures to reduce the size of the impact.
- **Repair**
  - Take action to repair and/or restore the affected environment.
- **Offset**
  - Implement measures to offset or compensate for the impact.

### 3.3.11 Residual Impact Assessment

Once feasible mitigation measures were identified and agreed, the ESIA team reassessed the potential impacts, assuming the mitigation measures were effectively implemented as planned.
In general, impacts with "Not Significant" or "Low Significance" residual impact significance were not considered to be of concern to the development of the Project. For adverse impacts of "Moderate" and "High" significance, an iterative process is undertaken to further investigate opportunities for mitigation, according to the hierarchy above. Where the significance cannot be further reduced, an explanation is provided of why further reduction is not practicable. Monitoring is required to confirm the measures used to mitigate adverse impacts are working properly and that the impact is not worse than predicted. Monitoring requirements are outlined in the respective assessment chapters.

### 3.3.12 Environmental and Social Management Plans

Environmental and Social Management Plans (ESMPs) have been developed to capture all mitigation and management measures and environmental and social commitments made within the ESIA Report. Adherence to these plans will be a condition of any Project construction and operation contracts awarded. It is noted that the ESMPs also incorporate environmental and social management commitments of Bulgaria and Turkey. How the ESMPs fit into this broader South Stream HSSE-IMS is described in Chapter 22 Environmental and Social Management.

### 3.4 Stakeholder Engagement

As part of the ESIA process, stakeholder engagement was and continues to be undertaken throughout the development of the Project to ensure that all interested parties are aware and informed of the Project and have an opportunity to provide input regarding potential Project impacts and mitigation measures. To date, consultations have been undertaken with:

- National authorities;
- Municipal and local authorities;
- Local communities;
- Marine area users;
- Local businesses;
- Non-governmental organisations (NGOs); and
- Academic and scientific organisations.

South Stream Transport has developed a Stakeholder Engagement Plan which identifies stakeholders and their interests, describes the consultation undertaken and that planned as part of the Project’s ESIA process, and establishes a framework for stakeholder engagement activities to be undertaken as the Project progresses beyond the ESIA phase.

A more stringent approach was taken in the assessment of ecological receptors of high sensitivity, such as critical habitat, or species classified as having vulnerable or above conservation status. In this case, residual impact significance of Low and above was a concern to the further development of the Project.
The stakeholder consultation process has helped the ESIA to scope potential impacts and concerns identified by the public. As indicated in Figure 3.1, stakeholder consultation has been a part of the ESIA process from the initial screening phase, and will continue with the submission of this ESIA, and during Project implementation to ensure the management of impacts takes stakeholder’s concerns into account.

Details of the stakeholder engagement process for the ESIA are discussed further in Chapter 6 Stakeholder Engagement.

This ESIA Report has been released to the public for review and comment. The purpose of this disclosure is:

- To help stakeholders understand the potential impacts, following the application of mitigation measures, that may arise as a result of the Project;
- To provide an opportunity for stakeholders to raise comments or concerns about the Project, and request any additional mitigation measures deemed appropriate; and
- To confirm to stakeholders that their opinions obtained through the stakeholder engagement process have been considered in both Project design and ESIA evaluation.

Further details about this disclosure are provided in Chapter 2 Policy, Regulatory and Administrative Framework and Chapter 6 Stakeholder Engagement.

### 3.5 Data Limitations

This ESIA Report has been based on design information available at the time of its preparation. Where necessary assumptions have been made and discussed in the relevant chapters. Consequently the ESIA has been undertaken on Project engineering design information at a Front End Engineering Design (FEED) level.

During the detailed design, Construction and Pre-commissioning, and Operational Phases of the Project, there may be a requirement to amend design elements or processes which results in a deviation from that presented in this Project Description. The Project has a management of change process to manage and track any such amendments, and to:

- Assess their potential consequences with respect to environmental and social impact; and
- In cases where a significant impact is likely to arise as a consequence of the amendment or change, to inform and consult with relevant parties on the nature of the impact and on proposed mitigation measures, where practical and appropriate.

All design changes will be added to a register of changes, which will summarise the change, the assessment, and the justification for South Stream Transport actions. The management of change process will be incorporated into the HSSE Management of Change Procedure, which is described in further detail in Chapter 22 Environmental and Social Management.

The Project design will continue to be refined to a final detailed design level, as informed by this ESIA. Any changes made to Project design following finalisation of this ESIA Report will be managed through the Management of Change Procedure (Chapter 22, Environmental and
Social Management), which includes the requirement to assess any potentially significant environmental and social impacts.

Comprehensive data have been used to inform this ESIA Report to enable sufficient confidence in the assessment conclusions. Notwithstanding the data set used, some gaps in baseline data necessitated some conservative assumptions as described in the relevant chapters and a precautionary approach to the mitigation measures adopted.

In this ESIA Report, predictions are made using accepted ESIA methods ranging from qualitative assessment and expert judgement to quantitative modelling. The technical discipline impact assessment sections in Chapters 8 to 18, detail specific relevant data and assumptions made.

4 Analysis of Alternatives

4.1 Introduction

The Project is the Russian Sector of the South Stream Offshore Pipeline, which is the offshore component of the South Stream Pipeline System. The objective of the South Stream Pipeline System is to develop a new gas supply route via the Black Sea that provides a safe and reliable means to export Russian gas to the countries of Central and South-Eastern Europe.

This chapter examines the technically and financially feasible alternatives to achieve the Project objective, which, consistent with the objective of the overall South Stream Pipeline System, is to form a key part of the new supply route via the Black Sea. These alternatives were considered during the Feasibility and Development Phases of the Project and have led to the validation of the Project as it is described in Chapter 5 Project Description.

Alternatives to the overall South Stream Pipeline System have not been considered within this ESIA Report, although reference is made to decisions made for the South Stream Offshore Pipeline and the wider South Stream Pipeline System. Such reference is made to provide context, particularly where decisions were made by third parties that directly influence the Project’s design, recognising that the Project is an integral part of the wider South Stream Pipeline System.

Alternatives that were considered and assessed during the Feasibility Phase of the Project are referenced to the source documentation in the text. As indicated above, not all alternatives that are described in this chapter were considered and assessed during the Feasibility Phase. Some were examined later during the Development Phase, which includes the ESIA process. The need to carry out further appraisal of alternatives as part of the ESIA process stemmed from a need to confirm that all routing and technical decisions did in fact result in the least possible environmental and social impact, prior to finalising the design of the Project. These further appraisals do not have separate references and the results of the appraisals are presented in this chapter as part of the ESIA documentation.

The objective of this chapter is to outline how the Project represents an optimised design that is technically and financially feasible whilst minimising overall environmental and social impacts. The assessment of impacts that will arise as the result of the Project, along with the identification of appropriate mitigation measures, is contained in Chapters 7 to 21 of this ESIA Report.

This chapter is structured to start with consideration of high level strategic options (e.g. the zero alternative) and progressively focuses in on the more detailed Project-specific alternatives considered as part of the Front-End Engineering and Design (FEED) process (e.g. shore crossing options and route refinement options) (Ref. 4.1 to Ref. 4.3). Routing and siting alternatives have been analysed in the context of the engineering, environmental, socio-economic and cultural heritage optimisations that have been carried out during both the Feasibility and Development Phases of the Project.
Chapter 4 Analysis of Alternatives

It is noted that there is a requirement to provide flexibility to construction contractors in determining the most efficient and cost-effective construction methodologies whilst ensuring compliance with Project standards and Project commitments. Specifically, it is recognised that, at the time of writing this ESIA Report, data gathering and detailed design are on-going. As a result, some detailed aspects of the Project design may be subject to change but these will not materially alter the findings of the ESIA or any associated mitigation measures. In such cases, rather than being discussed within this chapter, Chapter 5 Project Description provides an outline of the potential construction alternatives.

4.2 Approach to Analysis of Alternatives

As recommended in the International Finance Corporation (IFC) Performance Standards Guidance Note 1: Assessment and Management of Environmental and Social Risks and Impacts (Ref. 4.4), the ESIA Report includes “an examination of technically and financially feasible alternatives to the source of such impacts, and documentation of the rationale for selecting the particular course of action proposed.”

It is important to recognise that the South Stream Offshore Pipeline (and therefore the Project) is the offshore components of a larger South Stream Pipeline System. Consequently, the South Stream Offshore Pipeline and the Project (Russia Sector), which forms part of it, are significantly influenced by the route selection for the broader South Stream Pipeline System. Alternatives to the South Stream Offshore Pipeline as a whole are briefly discussed in this document (Sections 4.3 and 4.4) followed by the more detailed discussion of alternatives to the Project (Russian Sector).

Decisions taken by Gazprom prior to the establishment of South Stream Transport B.V. for the wider South Stream Pipeline System have significantly influenced the route selection (Ref. 4.1). Accordingly, this chapter briefly refers to the consideration of alternatives and decisions taken by Gazprom that have to a some extent predefined the Project design i.e. the general location of Russian landfall facilities and the routing of the offshore section of pipeline. Consequently the Analysis of Alternatives described in this chapter is structured to follow a ‘narrowing approach’ involving a series of logical steps, starting with the high-level alternatives (including those determined by third parties) followed by descriptions of more detailed alternatives (under South Stream Transport’s control). Using this commonly adopted narrowing approach, the Analysis of Alternatives considers alternatives in the following sequence:

- The ‘Zero’ Alternative;
- South Stream Offshore Pipeline alternatives:
  - Alternative means of gas transportation; and
  - Offshore (macro) routing.
- Project alternatives:
  - Landfall site selection;
  - Shoreline crossing technique (open cut vs. microtunnelling);
  - Onshore routing; and
  - The offshore route optimisation.
4.3 Zero Alternative

The zero alternative for the purposes of this ESIA Report is the situation where the Project (i.e. the Russian Sector of the South Stream Offshore Pipeline) does not proceed. Under the zero alternative for the Project there are no adverse environmental or social impacts in Russia, on land or in Russian waters, as there is no construction or operation of the pipeline in Russia. Any such option would imply that the Project does not impinge on Russian territory, Russian waters, or the Russian EEZ.

The need for the South Stream Pipeline System and therefore the Project is driven by Europe’s long-term demand for natural gas; further details are provided in Chapter 1 Introduction.

Should the Project not proceed, the entire South Stream Pipeline System with an offshore pipeline through the Black Sea would not proceed and the objective to provide a new supply route to the countries of Central and South-Eastern Europe via the Black Sea would not be met. This would in turn mean that diversifying existing supply routes to Central and South-Eastern Europe and providing additional supplies of natural gas to meet its growing energy demand would not be possible.

At the same time, the zero alternative would also mean that the Russian Federation would not benefit economically at the national level from the export of gas and at regional and local levels from sourcing employment, goods and services for the construction of the Project.

4.4 South Stream Offshore Pipeline Alternatives

4.4.1 Alternative Means of Gas Transportation

Based on the premise that gas will be exported via a new route across the Black Sea, consideration can be given to offshore transportation of gas by means other than pipeline systems. The main alternative to pipelines for transporting natural gas from Russia to Central and Southern European countries by sea is the liquefaction of natural gas at a Black Sea port in Russia and transportation of Liquefied Natural Gas (LNG) using LNG carriers to either:

- A port on the Western Black Sea coast (Bulgaria or Romania); or
- A port in southern Europe beyond the Turkish Straits.

The following factors were considered in the assessment of these alternatives:

1. Liquefaction and transportation of LNG to gas markets is usually undertaken for ‘stranded gas’ deposits where the source of gas is so distant and isolated from its markets as to make transportation by pipeline uneconomic;

2. Liquefaction would require the construction of a liquefaction plant on the Russian coastline. The onshore environmental impacts associated with the construction and operation of an LNG plant would be greater than those of a pipeline and associated compressor station;

3. This alternative would require the presence of an unloading jetty or offshore buoy and a regasification plant on the shores of a South European receiving country. In view of the
sensitivity and often designated protected status and recreational value of the Bulgarian and Romanian coastlines, it was considered undesirable to develop a large scale regasification plant on the coastal areas of Bulgaria or Romania. In order to avoid construction of a permanent regasification plant, export to an existing south European LNG regasification terminal could be considered; and

4. Transportation of LNG would require approximately 600 to 700 LNG carrier movements per year to export 63 bcm of natural gas per year. This would equate to approximately two full LNG carrier movements per day passing through the Turkish Straits, which include the densely populated areas adjacent to the Bosphorus Strait, Istanbul. In view of the hazardous nature of the cargo, the existing high density of maritime traffic through the Turkish Straits and the population density around the Bosphorus Strait, this number of vessels movements would introduce an additional and potentially unacceptable safety risk.

Based on the above, the LNG alternative is not considered further.

### 4.4.2 Offshore (Macro) Routing

Prior to selection of the site for the Russkaya Compressor Station (CS) to the south east of Anapa, eight potential offshore pipeline corridors were considered across the Black Sea; four offshore pipeline corridors from a shore crossing area near Beregovaya and four from a shore crossing area near Anapa, both located in the Russian Federation as shown in Figure 4.1.
Route alternatives

Option 1a - Anapa to Varna (Turkish waters)

Option 2 - Anapa to Varna (Ukrainian & Romanian waters)

Option 3 - Anapa to Constanta (Ukrainian waters)

Option 4 - Anapa to Constanta (Turkish & Bulgarian waters)

Discounted Offshore Pipeline Route Alternatives

Option 5 - Beregovaya to Varna (Ukrainian & Romanian waters)

Option 6 - Beregovaya to Constanta (Ukrainian waters)

Option 7 - Beregovaya to Constanta (Turkish & Bulgarian waters)

Option 8 - Beregovaya to Varna (Turkish waters)

Figure 4.1

Route alternatives

Option 1a - Anapa to Varna (Turkish waters)

Option 2 - Anapa to Varna (Ukrainian & Romanian waters)

Option 3 - Anapa to Constanta (Ukrainian waters)

Option 4 - Anapa to Constanta (Turkish & Bulgarian waters)

Discounted Offshore Pipeline Route Alternatives

Option 5 - Beregovaya to Varna (Ukrainian & Romanian waters)

Option 6 - Beregovaya to Constanta (Ukrainian waters)

Option 7 - Beregovaya to Constanta (Turkish & Bulgarian waters)

Option 8 - Beregovaya to Varna (Turkish waters)
The comparative assessment of these two locations, carried out by Gazprom (Ref. 4.2) as summarised in Section 4.5.1, showed that the location chosen for the Russkaya CS (near Anapa) had lower environmental impacts compared to the Beregovaya location.

As a result of the selection of Anapa as the proposed shore crossing location, route options 5, 6, 7 and 8 were discarded from further consideration. The four options taken forward for assessment (Options 1, 2, 3 and 4) are summarised in Table 4.1.

</tbody>
</table>

Of these four corridors, two cross the Turkish EEZ (Options 1 and 4) and two cross the Ukrainian EEZ (Options 2 and 3). Options 2 and 3 could not be surveyed within the timeframe required and were therefore discarded from further consideration. Further technical investigations were performed for Option 1, landing in Bulgaria and Option 4, landing in Romania (Ref. 4.3).

Various landfall site alternatives were considered on the Black Sea coast of southern Europe, in Bulgaria and Romania. This process identified two preferred shore crossing areas: one near the Bulgarian port of Varna and one near the Romanian port of Constanta.

After Bulgaria and Russia signed an Intergovernmental Agreement on South Stream, the remaining Romanian landfall alternative (Option 4) was no longer considered, leaving Option 1 as the preferred option. Following this decision, shore crossing sites in the vicinity of Varna on the Bulgarian Black Sea coast were further considered.

Option 1 was subsequently subject to route optimisation with consideration of a direct route across the Turkish EEZ rather than the deviation to the south. Option 1 was originally proposed to avoid the potential impacts of the southern edge of the Danube Delta sediment fan. Following further engineering investigation, it was concluded that due to the relatively low relief and inactive depositional nature of the outer submarine fan, the effects associated with deposition of sediment in the Danube fan system were minor. The direct line approach shown...
as Option 1a on Figure 4.1 was therefore adopted and subjected to further consideration of environmental and cultural heritage sensitivities (see Chapter 12 Marine Ecology and Chapter 16 Cultural Heritage).

4.5 Project Alternatives

4.5.1 Landfall Site Selection

Following the decision to construct an offshore pipeline system across the Black Sea, landfall sites on the Russian Black Sea coast and on the Black Sea coast of Southern Europe were selected.

The selection of the landfall site on the Russian Black Sea coast first took into account the requirement for a Compressor Station (CS) close to the coast. A large CS is necessary to increase gas pressure and pump the gas across the Black Sea. As mentioned in Chapter 1 Introduction, the CS will be designed and installed as part of the project known as "Expansion of the UGS (United Gas Supply System) to provide gas to South Stream pipeline" that is being developed by Gazprom.

The land-take requirements and environmental and safety considerations associated with the CS are more significant than those associated with the offshore pipelines. The site for a large gas compressor station requires gentle topography, safe and feasible connections with the onshore and offshore pipeline system and adequate distances from populated areas and from areas with special designation (e.g. nature reserves). Not many locations satisfied all these requirements and only two potential locations were identified by Gazprom on the Russian shores of the Black Sea:

- A location approximately 10 km southeast of the town of Anapa (the Russkaya CS); and
- Beregovaya CS, located approximately 5 km east of the town of Arkhipo-Osipovka.

The Russkaya CS location is a green field site in a relatively isolated location whereas the Beregovaya location is adjacent to the existing CS of the Blue Stream Pipeline.

The two locations were identified by Gazprom (Ref. 4.2) on the basis of available land of suitable morphology, existing land use, presence of transport infrastructure, distance from residential areas and other environmental and social constraints. The concept of bundling potential environmental and social impacts and thus confining such impacts to one location, with potential positive and adverse cumulative effects, was considered for the Beregovaya location, given its proximity to the CS of the Blue Stream Pipeline.

---

1 At this stage Gazprom divided pipeline into three distinct components: i) a pipeline system in Russia terminating at a Compressor Station (CS); ii) an offshore pipeline system (the South Stream Offshore Pipeline); and iii) an onshore distribution system in central and southern Europe. These three components became distinct projects with separate management companies, engineering and permitting history.

2 The Blue Stream gas pipeline crosses the Black Sea delivering Russian natural gas to Turkey.
The comparative assessment of the two selected locations, carried out by Gazprom (Ref. 4.2), concluded that the location of the Russkaya CS had fewer environmental impacts compared to the Beregovaya location. This included lower impacts on air quality and noise, lower suspended solids in runoff, lower usage of petroleum products, lower impacts on marine biological resources and greater distances from protected areas (further details are provided in Appendix 20.1). Bundling impacts at Beregovaya was in this instance considered to be unacceptable because of the cumulative impacts associated with the contemporaneous operation of the two facilities. On this basis, the Russkaya CS site was selected and the decision was subsequently approved by Russian environmental agencies at both the Federal and Regional level during meetings held on the 22 to 29 September 2011.

As a result of the selection of the Russkaya CS site, the Anapa landfall was considered for further technical evaluation by Gazprom.

4.5.2 Shoreline Crossing

The selection of the shore crossing location was dictated by the requirement to keep the pipelines at a safe distance from residential and recreational areas (see Figure 4.2).

For ESIA Report

© URS Infrastructure & Environment UK Limited

This document has been prepared in accordance with the scope of URS' appointment with its client and is subject to the terms of that appointment. URS accepts no liability for any use of this document other than by its client and only for the purposes for which it was prepared and provided. Only written dimensions shall be used.
Based on this requirement, the only feasible shore crossing corridor for a trenched crossing required the pipelines to cross the main road from Anapa and Varvarovka to Sukko, climb up a steep coastal ridge (17% gradient), cross a coastal path and finally descend a steeper slope (37% gradient) to reach the Black Sea shore. Figure 4.2 shows the route of the pipelines.

A preliminary engineering and environmental analysis (Ref. 4.3) of the shore crossing feasibility indicated that in addition to significant engineering challenges, due to the steepness of the slope (Figure 4.3), an open cut approach to the shore crossing would have resulted in additional environmental impacts, including the need to remove larger areas of sensitive natural habitats, which would result in habitat loss and fragmentation.

**Figure 4.3 Russia Shore Crossing Coastline**

Alternative trenchless shore crossing techniques were therefore assessed. The chosen technique is based on the construction of a tunnel\(^4\) for each pipeline from a location to the east of the Anapa-Sukko road to the seabed, at a water depth of approximately 23 m and a distance of 400 m from the shore. This option includes the additional benefit of removing the need to carry

---

\(^3\) Natural habitats present comprise notable plant species, such as Juniperus excelsa and Juniperus foetidissima listed as species of concern on local, regional and international Red Data Books.

\(^4\) Trenchless alternatives included Horizontal Direction Drilling (HDD) and Microtunnelling. Microtunnelling was selected over HDD because it allows greater flexibility and reliability in differing sub strata.
out dredging and pipeline construction activities in the most sensitive section of the marine environment (0 to 20 m water depth).

Following the Analysis of Alternatives, microtunnelling was selected on the grounds that a steep angled open cut method would present significant engineering challenges. This trenchless alternative would also result in fewer environmental impacts.

### 4.5.3 Onshore Routing

The route of the onshore sections of the Offshore Pipeline Project shown in Figure 4.2 was chosen to maximise the use of modified vineyards thereby minimising impacts on natural habitat whilst also considering mandatory exclusions zones for safety purposes. The onshore route is further described in Chapter 5 Project Description.

### 4.5.4 Offshore Route Optimisation

The route selection process progressed with the optimisation of the offshore route across Russian waters in the three main oceanographic units of the Project:

- The continental slope;
- The continental shelf; and
- The abyssal plain.

A corridor centred on a preliminary route alignment was surveyed between 2009 and 2011 to identify engineering and environmental constraints and marine archaeological features. The width of the corridor extended between 1.2 km and 2 km and up to 9 km in technically challenging areas such as the continental slope where the pipelines will be laid in separate canyons. Given the technical complexity associated with the identification of a continental slope crossing, this aspect was assessed first. After selecting a suitable continental slope crossing, the routes from the continental slope to the Anapa landfall (across the continental shelf and the shoreline) and the route across the abyssal plain to the border with the Turkish EEZ, were assessed.

#### 4.5.4.1 Continental Slope Crossing

The continental slope is an unstable region where the depth of the sea rapidly changes and the seabed is generally characterised by unstable sediments, dynamic conditions (e.g. submarine slumps and sediment flows) and irregular morphology.

The continental slope near Anapa is characterised by an extensive network of canyons. The main canyon (known as the Anapa canyon) corresponds with the sediment transport path from the Sea of Azov to the Black Sea and is a relic feature of the estuaries of the Don and Kuban rivers. The Anapa canyon runs parallel to the Russian Black Sea coast. The northern slope of the Anapa canyon is steep and itself incised by smaller canyons. The floor of the canyon is further incised by a trough, which would have required a complex crossing. Throughout these morphological features of the seabed, sediment is unstable: massive sediment failures create turbid flows and submarine slumps, which could compromise the integrity of the pipeline. The rugged morphology associated with exposed rock outcrops and localised pockets of sediment...
also create stability and engineering challenges. For these reasons, extensive surveys were carried out to identify feasible crossing locations. Figure 4.4 shows the potential pipeline route through the Anapa Canyon.

**Figure 4.4 Anapa Canyon Crossing**

![Anapa Canyon Crossing Diagram](image)

Two stable lateral canyons running down the continental slope were identified during the survey programme. On the basis of the width of the canyons, it was established that the best technical option included routing two pipelines in each canyon. Figure 4.5 shows the potential route of the four pipelines through these canyons diverging by up to approximately 4.8 km at the widest part.
Having selected the preferred locations for crossing the continental slope, extensive geophysical and engineering surveys were carried out to identify both the safest routes across the continental slope and to determine if any environmental or cultural constraints were present along the preferred routes.

No significant environmental constraints that could influence the route selection were identified. The route selection process, therefore, progressed on the basis of technical feasibility and non-environmental sensitivities including a thorough review of the canyon's morphology and of the potential for the occurrence of geohazards and cultural heritage objects (CHO).

Three positively-identified CHOs are located on the continental slope. These three objects are not considered archaeological monuments, but are CHO (‘science and technology objects’) in accordance with Federal Law No.73-FZ dated June 25 2012. Furthermore, these objects were not in close proximity of the pipeline route and therefore did not influence the pipeline route selection. Chapter 16 Cultural Heritage provides further detail on these objects, their value and measures required to ensure their protection.
4.5.4.2 Continental Shelf Crossing

Currently known environmental, socio-economic and cultural heritage constraints on the continental shelf include environmental conservation areas in the shallow water environment (less than 20 m depth), military training areas, ammunition dumping grounds and shipping routes (Figure 4.6 and Figure 4.7). These areas were largely avoided during route selection.

Two further factors were considered in the assessment of alternative routes for crossing the Russian continental shelf:

1. The most sensitive marine habitats on the continental shelf are located at depths between 0 and 50 m; and
2. Below 30 m water depth, where conditions are stable, the risks from anchors and ships’ hulls are minimal; and pipelines typically do not need to be buried. Consequently, trenching associated with the burial of pipeline is typically not required below 30 m water depth.

On the basis of the above considerations, the selected corridor runs parallel to the coast at a depth of more than 50 m for most of its length, therefore minimising any potential impacts on marine ecosystems from disturbance of water quality associated with dredging.

Marine habitat surveys were also carried out to validate the suitability of the chosen route (Chapter 12 Marine Ecology). These initial surveys, which have informed the assessment of impacts to the marine ecology, did not reveal any significant ecological sensitivities that warranted alteration of the route to minimise impacts.

4.5.4.3 Abyssal Plain Crossing

Following selection of the continental slope crossing, a preliminary corridor was identified to route the pipelines across the abyssal plain to the border with the Turkish EEZ.

No significant engineering or social constraints were identified on the abyssal plain. In addition, there was very limited information available on the environmental constraints (e.g. marine ecosystems). Therefore, a straight line route was initially adopted.

The final route alignment was subsequently selected on the basis of further geophysical, environmental and cultural heritage surveys. The entire corridor was mapped and the geological, bathymetric and cultural features were recorded for further analysis.

Specifically, a thorough review of the seabed features was carried out to determine the presence of features of biological importance such as microbial mats and CHOs. The findings of this review are included in Appendix 7.1 Abyssal Plain Report.

Whereas no significant features of biological importance were identified, four potential CHOs have been identified on the abyssal plain within 150 m of the pipeline route and seabed intervention works. These potential CHOs were first identified in side-scan sonar images and have been earmarked for visual inspection via submersible ROV to determine their identity and potential cultural significance, prior to construction of the pipeline (Ref. 4.4). A conservative approach has been taken to ensure that the objects are not impacted and route adjustments will therefore be made during the detailed design phase of the Project to maintain the 150 m buffer between the pipelines and the objects, regardless of their designation as CHOs. Chapter 16 Cultural Heritage discusses these objects, their potential value and measures required to ensure their protection in more detail.

4.6 Summary

This chapter summarises the Analysis of Alternatives performed initially by Gazprom during early feasibility studies and then by South Stream Transport as part of the South Stream Offshore Project, Russian Sector. To some extent, the nature and location of the Project was determined by factors beyond the control of South Stream Transport, particularly in respect of the location of the landfall section, which was constrained by the selection and siting of the Russkaya Compressor Station. Nevertheless, the Analysis of Alternatives has adopted a typical narrowing approach, starting with high level alternatives such as means of transporting gas across the Black Sea, honing in on more detailed consideration of alternatives, such as consideration of detailed pipeline routing. The flow diagram below summarises the analysis of alternatives process, including the rationale for discarding certain alternatives.

---

5 Seabed intervention works include all activities involving the disturbance of the seabed with the exception of pipe lay. For example, seabed intervention activities would include activities include rock placement to correct free span areas where the seabed is uneven, dredging, trenching, placement of support structures etc.

**The ‘No Project’ option was dismissed.**  
Refer to Chapter 1 – the Project need. |
| Offshore Pipeline vs LNG (LNG Plant, LNG carriers, regasification) | LNG could be exported to a new regasification facility in Romania, Bulgaria or beyond central and southern Europe, however:  
- Construction of unloading facilities and a regasification plant on the shores of southern or central Europe is undesirable.  
- It is not the Project intent to export beyond central and southern Europe.  
- Transit through the Turkish Straits, for example to Italy, carries higher safety and environmental risks. |
| Landfall – Russia (site selection) | LNG dismissed on the grounds that a pipeline system was considered more safe and reliable avoiding the need for to construct a new regasification plant on the Black Sea coast/ship LNG through the Turkish Straits.  
Driven by the need to have a large new build CS nearby – two sites identified by Gazprom were Anapa (Russkaya CS) and Arkhipo-Osipovka (adjacent to the Blue Stream Beregovaya CS)  
Studies performed by Gazprom concluded that a compressor station at the Anapa site would have less environmental impact. The cumulative impacts at Beregovaya were considered unacceptable. |
| Offshore routing (Macro alignment*) | Beregovaya was discarded due to concern over significant cumulative environmental impacts.  
Option 2 and 3 were discarded because survey work would have resulted in schedule delays.  
Option 4, landing in Romania, was discarded after strategic transit agreements were made with Bulgarian entities.  
**Option 1 was the preferred alternative** selected for detailed route alignment studies after 1, 3 and 4 were discarded. |
| Shore crossing technique (Anapa, Russia) | Open cut is typically less expensive, however open cut on a steep cliff face would be technically difficult and likely to result in environmental damage to a sensitive habitat.  
**Open cut discarded due to technical difficulties and risks to long term pipeline stability.** |

*Macro alignment refers to the general routing of the pipeline along the seabed. Other factors such as the specific routes and alignment details are discussed in the text.*

5 Project Description

5.1 Introduction

This chapter of the Environmental and Social Impact Assessment (ESIA) Report describes the technical components of the Project and forms the basis for the assessment of impacts undertaken in the technical studies found in Chapters 8 to 21 of this ESIA Report. The physical aspects of the Project are set out in terms of the Construction, Pre-Commissioning, Operational, and Decommissioning Phases of the Project.

As described in Section 1.2 of Chapter 1 Introduction, the Project is the Russian Sector of the South Stream Offshore Pipeline, which itself, is the offshore component of the South Stream Pipeline System that will deliver natural gas from Russia to the countries of central and south-eastern Europe.

The Project commences at a pipeline tie-in (where two pipeline ends are welded together) approximately 100 m upstream of the landfall facilities, which connects the Project pipelines to the project known as “Expansion of the United Gas Supply System” that is being developed by Gazprom Invest. The landfall facilities will be connected to the Russkaya Compressor Station (CS) via four 3.2 kilometres (km) long onshore pipelines. The Russkaya CS, and the four connecting pipelines (upstream of the aforementioned tie-in location), are being developed by Gazprom Invest and are not part of the Project. The tie-ins to the “Expansion of the United Gas Supply System” are located approximately 10 km south of the town of Anapa, in the Krasnodar Krai (or region). See Section 5.2.1 for illustrative figures.

From the landfall facilities, the Project pipelines will extend in a generally south-westerly direction for approximately 2.4 km to four microtunnel entry shafts. The pipelines will continue in a south-westerly direction through microtunnels for approximately 1.4 km where they will emerge from the tunnels approximately 400 m offshore. Microtunnelling has been selected for the shore crossing predominantly due to the technical difficulties associated with the crossing of the high cliffs at the shore crossing location. Due to the steepness of the slope and the presence of rock, open-cut installation of the onshore pipeline across the sea cliffs is not feasible. The pipelines will then extend through Russian Territorial Waters and the Russian Exclusive Economic Zone (EEZ) for approximately 225 km in a generally south and south-westerly direction to the EEZ boundary of Russia and Turkey (the downstream boundary of the Project). From here, the South Stream Offshore Pipeline will continue across the Black Sea, via the Turkey and Bulgaria EEZ towards Varna in Bulgaria where it will make landfall.

The proposed route of the Pipeline was selected following an extensive analysis of alternatives as described in Chapter 4 Analysis of Alternatives. Final pipeline route alignments may be further optimised during the detailed design phase; however any such changes are not anticipated to result in changes to the impact assessments presented in technical Chapters 8-21 of this ESIA Report. Should any major changes to the pipeline routing be required, which may affect the results of the ESIA, the management of change process described in Section 5.11 will be followed.
Chapter 5 Project Description

As part of the Project design process, measures to avoid or minimise impacts were identified and incorporated into the design. These are referred to as design controls and include physical design features and management measures. They are based on Good International Industry Practice (GIIP) and are intended to avoid or control unacceptable impacts. Specific design controls are described in this Project Description. Their role in controlling impacts on environmental, social and cultural heritage impacts is further discussed in Chapter 3 Impact Assessment Methodology. Where the outcome of the ESIA indicates that design controls are insufficient to manage an impact to an acceptable level, further measures have been identified. These measures have been termed “mitigation measures” and are described in respective chapters and detailed in Environmental and Social Management Plans.

5.2 Project Components

The permanent Project components comprise of the following main elements:

- Four 32-inch (813 millimetre (mm)) diameter buried onshore steel pipelines approximately 100 metres (m) long from the tie-in to the “Expansion of the United Gas Supply System” to the landfall facilities;
- Four 32-inch (813 mm) diameter buried onshore steel pipelines approximately 2.4 km long from the landfall facilities to the microtunnel entry shafts;
- Four 2.5 m diameter, 1.4 km long microtunnels each housing one 32 inch (813 mm) steel pipeline from the microtunnel entry shafts to the offshore microtunnel exit pits;
- Four 32-inch (813 mm) diameter subsea steel pipelines, approximately 225 km in length, from the microtunnel exit pits to the border of the Russian and Turkish EEZ;
- Fenced landfall facilities (approximately 4.85 hectares (ha) in area), which will primarily consist of:
  - Metrology equipment;
  - Four Pipeline Inspection Gauge (PIG) trap facilities (one per pipeline);
  - Eight Emergency Shutdown (ESD) valves (two per pipeline);
  - Eight block valves (two per pipeline);
  - Other valve systems including ball line valves, and temperature control valves (TCV);
  - A gas heating system;
  - Four 24-inch (610 mm) diameter steel pipelines, each approximately 106 m long;
  - Pre-fabricated containers to provide office and storage space, sanitary facilities and house electrical and instrumentation (E&I) equipment;
  - A 21 m high vent stack and associated piping;
  - Isolations joints;
  - Two 10 kilovolt (kV) buried power cables connecting to the Russkaya CS;
  - Two buried fibre optic communication cables connecting to the Russkaya CS;
  - Rainwater drainage system;
- An area of cut and fill slopes (approximately 4.83 ha in area) surrounding the landfall facilities;
- Access road and car parking;
• Cathodic protection system, including an onshore anode bed;
• A permanent Right of Way (RoW) approximately 95 m wide above the landfall section trenched onshore pipelines;
• Exclusion zones extending to 410 m from the outermost landfall section pipelines and landfall facilities for the protection of public health and infrastructure; and
• A 0.5 km exclusion zone (either side of the centreline of the outermost pipelines - except for a section on the Russian continental slope where the pipelines diverge into two groups of two), extending from the seabed to the surface of the sea, and from the microtunnel exit pits to the Russian and Turkish EEZ boundary.

Further details on the permanent Project components are provided in Sections 5.2.4 and 5.2.5 and information on the Operational Phase safety exclusion zones are provided in Section 5.6.6 and 5.6.7. Information on the temporary facilities required for the construction of the permanent Project components is provided in Section 5.3.4.1.

5.2.1 Project Area

The Project Area (defined in Section 1.2.1 and illustrated in Figure 1.5) is subdivided into the following sections: landfall, nearshore and offshore, primarily in relation to the different construction activities employed in each section. The landfall, nearshore and offshore sections of the Project Area are shown in Figure 5.1 and Figure 5.2 respectively and are described below. Note that the Project Area sections are associated with the construction activities and have no ecological meaning.

5.2.1.1 Landfall Section

The landfall section of the Project Area, including the landfall facilities, is approximately 4 km in length. Within this section the pipelines will be buried for the first 100 m upstream of the landfall facilities and for 2.4 km downstream of the landfall facilities using open-cut construction techniques. For safety reasons the buried landfall section pipelines will have a minimum soil cover of 1.5 m. For the remaining 1.4 km each pipeline will be housed in a microtunnel which will terminate approximately 400 m from the coast in water depth of approximately 23 m. The permanent onshore landfall facilities (approximately 142 m wide) are also included within the landfall section.

The area of the landfall section is primarily defined by the maximum operational safety exclusion zone of 410 m width surrounding the Pipeline and the landfall facilities. While the entirety of this area may not experience physical impacts, there will be restrictions on future land use and development within the exclusion zone. Within this area, a 95 m operational pipeline RoW will be permanently established above the pipelines. Outside of the operational safety exclusion zone, the landfall section of the Project Area also includes a temporary construction access road, a bypass road that will be constructed for permanent use, but only used by the Project during the Construction Phase and potential temporary transfer site (if required by contractor). The temporary road will link the microtunnel construction site to a permanent access road being constructed by Gazprom Invest as part of the “Expansion of the United Gas Supply System”.

URS-EIA-REP-204635 5-3
The bypass road will link the Varvarovka – Gai Kodzor public road to Gazprom Invests’ permanent access road, in order to provide an access road to the landfall facilities construction site. Refer to Section 5.3.3 and Figure 5.8 for further information on the permanent and temporary access roads required to support the Project.

5.2.1.2 Nearshore Section

The nearshore section of the Project Area commences at the exit point of the microtunnels, located approximately 400 m from the coast at a water depth of approximately 23 m and extends approximately 425 m out to a water depth of 30 m where an above water tie-in will be made following the completion of pre-commissioning activities of the landfall and nearshore section pipelines. From the microtunnel exit point the pipelines will be buried in trenches to a depth of approximately 2.5 - 3 m for a distance of approximately 170 m. From here, out to the edge of the nearshore section (30 m water depth), the pipelines will be coated in concrete and laid directly on the seabed. Concrete coating is to provide protection from third party activities and stability from sea currents. The pipelines are pre-coated before delivery to South Stream Transport.

5.2.1.3 Offshore Section

The offshore section of the Project Area extends from the edge of nearshore section at 30 m water depth (where an above water tie-in will be made) to the border of the Russian and Turkish EEZs in the Black Sea, passing through approximately 225 km of Russian waters, of which 50 km lie within Russian territorial waters and 175 km lie in the Russian EEZ. In the offshore section, the pipelines will be laid directly on the seabed. In the offshore section, the pipelines will be coated in concrete out to a water depth of approximately 88 m.

5.2.2 Associated Facilities

As described in Chapter 1 Introduction, the Project will rely on other facilities that are not under the direct control of South Stream Transport and typically located outside of the Project Area. In line with the OECD Common Approaches definition for associated facilities these include "facilities that are not a component of the project but that would not be constructed or expanded if the project did not exist and on whose existence the viability of the project depends; such facilities may be funded, owned, managed, constructed and operated by the buyer and/or project sponsor or separately from the project.” (Ref. 5.1). The Project associated facilities are consistent with this definition and include:

- The Russkaya Compressor Station (CS) located immediately upstream of the Project in Russia being developed and managed by Gazprom Invest; and
- Designated existing quarries for sourcing material / aggregates, where those existing quarries would require significant expansion for the sole purpose of supplying the Project.

---

1 OECD Common Approaches are the primary Environmental and Social Standards applicable to the Project. Further details are provided in Chapter 2 Policy Regulatory and Administrative Framework.

There are existing Ports in Bulgaria that will be upgraded as part of the Project in order that they can be used as Marshalling Yards for the Project. Use of the Marshalling Yards is described further in Section 5.3.2.1.

5.2.3 The Russkaya Compressor Station

As described in Chapter 1 Introduction, the landfall facilities will be connected to the Russkaya CS via four 3.2 km onshore pipelines (Figure 5.1). The four 3.2 km connecting pipelines, and the Russkaya CS are not part of the Project, but will be designed and installed as part of a separate project known as the “Expansion of the United Gas Supply System”, which is being constructed by Gazprom Invest. However, the CS provides the pressure necessary to drive gas through the Project pipelines across the Black Sea, and therefore it is considered to be an associated facility. The main elements of the Russkaya CS and its construction and operation are summarised briefly in this Section. The CS is described in more detail in Appendix 20.1.

According to the Russkaya EIA (Ref. 5.2), the Russkaya CS includes approximately 50 ha of permanent landtake for the CS facilities, and comprises the following main elements:

- Input pipelines and gas inlet unit that will connect the main gas pipeline with the gas treatment unit;
- Gas treatment unit that will treat gas by removing contaminants, such as solids, water and hydrocarbon condensate;
- Compressor works, that will comprise the gas pumping units (GPUs) with individual gas air cooling units;
- Gas flow-rate metering unit that will measure the commercial gas flow-rate and determine the chemical composition of the transported gas;
- Supporting facilities and utilities, such as access roads, a gas processing unit for internal power needs, power stations, a boiler unit for heat supply, water supply and treatment facilities, wastewater drainage and treatment facilities; and
- Materials and equipment depot (MED) to provide for storage of materials and equipment. The MED will include an entry area with changing rooms, heated warehouse, cooled warehouse, open storage area, automatic diesel power station, diesel storage tank and local treatment facilities for rainwater.

5.2.3.1 Inlet Unit

The inlet unit will connect the Russkaya CS to the upstream gas pipeline. A control unit will provide for safe operation of CS inlet unit and pipelines, protecting them from pressure fluctuations.

5.2.3.2 Gas Treatment Unit

The gas treatment unit will remove solids, water and hydrocarbon condensate in order to prevent contamination and erosion of the CS equipment and pipelines. Products of treatment will be transported for recycling / disposal at licensed facilities.
5.2.3.3  Gas Compressor Works

The compressor works will comprise 32 megawatt (MW) unit capacity gas pumping units (GPUs) equipped with full pressure turbo-compressors (Ref. 5.2). During Stage 1, the works will consist of seven GPUs. This will be expanded during Stage 2 to consist 14 GPUs which will increase the maximum total capacity to 448 MW, and the maximum processing capacity to 63 billion m$^3$/year (Ref. 5.3). Gas will be compressed at the CS for 24 hours a day, 7 days a week. The schedule for these two stages is summarised in Section 5.2.3.8.

5.2.3.4  Access Roads

A permanent access road will be constructed by Gazprom Invest to the Russkaya CS site. It is understood that this access road will have a permanent width of approximately 25 m (including shoulders) and will be hard surfaced. The construction corridor width for the road will be approximately 41 m wide. Temporary access roads will be constructed to the construction site and site accommodation, with temporary road surfacing of precast concrete slabs (Ref. 5.2).

5.2.3.5  Power Supply

The main power supply to the Russkaya CS will be a natural gas power plant, consisting of seven 1.5 MW gas turbines (five in duty, one reserve, one repair). An emergency automatic diesel power station will be used as a reserve source of power in case of a power cut (Ref. 5.2).

5.2.3.6  Water Demand and Supply

Construction

During construction, 7 m$^3$ per day of water will be required for production and engineering needs (Ref. 5.2). Water will be delivered from the existing water supply systems of nearby settlements and stored in a tanker.

Pre-Commissioning

The total demand for water for hydrotesting is estimated to be 3,000 m$^3$ (Ref. 5.2). To accumulate this volume, a temporary earthen insulated settling pit will be constructed near the Russkaya CS site. Water will be delivered to the site from existing supply systems in nearby settlements via trucks (Ref. 5.2).

Operation

During operations at the Russkaya CS it is estimated that approximately 152 m$^3$ per day of water will be required for use in the CS plant, household and potable needs, and for watering the area (Ref. 5.2). Water will not be used in the main technical processes at the CS.

5.2.3.7  Landfill and Waste Facilities

According to the Russkaya EIA (Ref. 5.2), contracts will be signed with licensed organisations for waste recycling, disposal, and reprocessing prior to the commencement of construction and operation of the Russkaya CS.
Construction

Construction waste will comprise solid refuse waste, vegetation and mineral soil surplus, stumps and cutting debris, and will be transported to approved sites. The total amount of construction waste generated is predicted to be approximately 502,484.5 tons (Ref. 5.2).

Operation

All industrial and domestic wastes produced during CS operation will be incinerated at the station site or transferred to licensed facilities. The annual amount of waste generated at the site is predicted to be approximately 164.6 tons (Ref. 5.2).

5.2.3.8 Construction Phase

Indicative Construction Schedule

The main construction period for Stage 1 of the Russkaya CS is estimated to be 34 months, from early 2013 until approximately October 2015. Stage 2 of the construction is estimated at 34 months, with completion in 2018 (Ref. 5.2).

Construction Works

Construction Materials

During the preparatory period, quarry soil will be transported to site via trucks and used to install temporary platforms and roads, and to maintain roads used during the construction phase (Ref. 5.2). Industrial equipment, pipes, soil, construction cargo, and labourers will all be transported to site by vehicles.

5.2.3.9 Pre-Commissioning, Commissioning and Operation

The Pre-Commissioning phase will involve testing the pipelines for durability and checking for leaks using the hydraulic method.

Process discharge of gas will be performed during the commissioning stage.

During operation, gas will be transported through the Russkaya CS via the following sequence: supply, treatment, compression, cooling and metering. Operational procedures centre on monitoring and maintenance of the CS facilities.

5.2.4 Pipeline Routing, Spacing and Operational Exclusion Zones

In general the four pipelines shall be laid parallel to each other in such a fashion that minimises the overall pipeline length and extent of the onshore RoW and offshore exclusion zones. However, detailed design engineering may require some final deviations to the design should any changes be required they are anticipated to be minor and are not anticipated to alter the results of this ESIA Report. Should any major changes to the pipeline routing be required, which may affect the results of the ESIA Report, the management of change process described in Section 5.11 will be followed.
In the landfall section of the Project Area, the distance between the pipelines in open-cut trenches is approximately 19 m. However, the spacing between the pipelines housed in the microtunnels increases from 26 m at the entry shafts to approximately 50 m at the exit pits located approximately 400 m from the coast. Throughout the nearshore and offshore sections, the pipeline spacing will range between 50 and 4,300 m (where the pipelines diverge down two canyons on the continental slope) measured from the centreline of the pipelines, although in general they are approximately 100 m apart.

Operational Phase exclusion zones and permanent land take is required to ensure the safety of the landfall section pipelines. The permanent RoW will be approximately 95 m wide (19 m either side of the centreline of the two outside pipelines and 19 m between the centreline of each pipeline). In addition to the permanent RoW there will be three Safety Exclusion Zones for the protection of public health and infrastructure, which go out to a maximum distance of 410 m from the outermost pipelines and landfall facilities. Further information on permanent land use and onshore exclusion zones are provided in Section 5.6.6.

During the Operational Phase of the Project an exclusion zone of 0.5 km either side of the outermost pipelines will be put in place above the offshore and nearshore section pipelines for the entire length of the pipelines within the Russian EEZ (except for a section on the Russian continental slope where the pipelines diverge into two groups of two). This will restrict activities that may damage the pipelines. Further information on the offshore exclusion zones is provided in Section 5.6.7.

### 5.2.5 Permanent Landfall Facilities

The landfall facilities will occupy an area of approximately 4.85 hectares (ha). The areas of cut and fill side slopes surrounding the landfall facilities are approximately 4.83 ha. The location of the landfall facilities is shown in Figure 5.2 and the indicative layout of the equipment is shown in Figure 5.3 and Figure 5.4.

Landfall Facilities

Towards microtunnel (offshore)

Safety Valve Station

Tie-in to United Gas Supply System (Gazprom invest)
Within the landfall facilities there will be pipe and equipment installed both above and below ground as illustrated in Figure 5.5.

The main components of the landfall facilities are the metrology equipment for monitoring the operations at the landfall facilities (gas temperatures, pressures etc.), PIG traps, electrical heating system, a venting system for pipeline depressurisation and customised pre-fabricated containers, that will serve various purposes including providing office space, sanitary facilities and housing E&I equipment to monitor the operating conditions of the pipelines. The final number and dimensions of the containers will be confirmed during the detailed design phase. However, this is not anticipated to affect the result of the impact assessments reported in Chapters 8-21 of this ESIA Report.

The landfall facilities will also include a number of valve systems including ESD valves, block valves, ball line valves, temperature control valves (TCV) and flow control valves (FCV).

Within the landfall facilities, each 32-inch pipeline will pass through a reducer (32-inch x 24-inch) which decreases the pipeline diameter to 24-inch, leading to a 32-inch x 24-inch barred tee (a type of T-shaped pipe fitting) upstream of the PIG traps. The 24-inch pipeline is required in order to connect to the metrology equipment. From the barred tee, the 32-inch pipeline diverges. In one direction the pipeline leads to a PIG trap and in the other direction the pipeline continues downstream through the landfall facilities as can be seen in Figure 5.4. A schematic of this process is shown in Figure 5.3.

The landfall facilities will be provided with power by buried cables which will run from the Russkaya CS to the landfall facilities. A fire and gas detection system will also be installed at the landfall facilities. The landfall facilities will be unmanned, except during maintenance activities, and will be controlled from a Central Control Room (CCR) and a Back Up Control Room (BUCR) located in Amsterdam.

The main elements of the landfall facilities are described in the following sections and permanent access routes to the landfall facilities are described in Section 5.3.3. Further information on permanent land take requirements for the Pipeline is provided in Section 5.6.6.

5.2.5.1 Monitoring Equipment

The E&I equipment required to monitor the operation of the South Stream Offshore Pipeline will be housed in customised pre-fabricated containers located with the landfall facilities. The monitoring equipment will continuously measure the gas composition (including water and hydrocarbon dew point), temperature, flow rate and pressure of the gas being transported. It is anticipated that approximately five containers may be required to house the necessary E&I equipment.

5.2.5.2 Emergency Shutdown Valves

Consistent with GIIP, the landfall facilities in Russia will have local ESD valves installed for each pipeline. An ESD valve is a hydraulic actuated and spring return valve designed to stop the flow of a hazardous substance (i.e. the gas) upon the detection of a potentially dangerous event or non-standard operating conditions. The ESD valves will quickly enable the offshore section pipeline to be isolated from the landfall facilities in case of a rupture or leak. This minimises risk
of possible harm to people, equipment or the environment. The ESD valves will be located in below ground concrete pits and are designed to operate in the event of plant malfunction or fire. The location of the inlet and outlet ESD valves are shown in Figure 5.4.

5.2.5.3 Block Valves

Each pipeline within the landfall facilities will be equipped with block valves. The block valves enable a segment of the pipeline to be isolated for maintenance work. Block valves are not as quickly operated (opened / closed) as the ESD valves described above, which are used in response to an emergency situation.

5.2.5.4 Pipeline Inspection Gauge Trap Facilities

A bidirectional PIG trap will be constructed for each 32-inch pipeline. PIG traps are used for inserting PIGs into a pipeline then launching, receiving, and finally removing them without flow interruption. The PIG trap will be used to send and receive PIGs during pre-commissioning tests and to receive PIGs during maintenance activities in the Operational Phase. PIGs are used for activities such as checking for defects (gauging), cleaning, drying and inspection of the inside of the pipeline.

5.2.5.5 Gas Heating System

A gas heating system will be employed to heat the gas to maintain the temperature of the gas above the minimum design requirements of -10°C. This heating system will not be required on a continuous basis and will only be employed during start-up operations following a planned or emergency shutdown event and at certain gas throughput quantities. It is estimated that the heaters will be required to operate for between one and three days during start-up operations depending on the size of heater used and length of shutdown period.

5.2.5.6 Vent System

The venting system is designed for venting the gaseous inventory of the pipework within the landfall facilities to the atmosphere (to depressurise) via eight 3-inch vent pipes in cases of planned shutdown of the pipelines. Each of the vent pipes will be mounted to a single 21 m high vent stack. For safety purposes, the location of the vent stack structure is chosen such that the prevailing wind blows gas away from the landfall facilities. Consequently the vent stack will be located approximately 70 m from the nearest pipework within the landfall facilities. Flow of gas to the vent stack is controlled by blow down valves (BDV). The BDV is a fail-safe actuated valve with downstream piping leading to a local vent pipe. During normal operations, the vent stack will not emit any gas. Venting will only take place during planned maintenance or shutdown activities that may require gas within certain areas of the landfall facilities to be released to atmosphere. The vent stack will be fitted with appropriately designed silencers to reduce the noise associated with the venting process. There will be no flaring from the vent stack.
5.2.5.7   Auxiliary Facilities

Fire and Gas Detection System

The purpose of the Fire and Gas (F&G) detection system is to protect and alert personnel and assets from the consequences of a fire and/or gas release. The F&G detection system is a safeguarding system which acts completely autonomously from other safety systems. The landfall facilities F&G detection system will include a number of strategically placed gas, flame and smoke detectors. The containers housing the E&I equipment will also be fitted with gas, flame and smoke detection systems as appropriate.

In an emergency case the landfall facilities will be isolated from the offshore pipeline and Russkaya CS in Russia and the Receiving Terminal in Bulgaria. There is no requirement for emergency venting (i.e. venting is not part of the ESD logic). However, provisions exist to enable a manual depressurisation of the landfall facilities, if required.

Provisions for active firefighting activities exposing personnel are not foreseen for fire protection of the equipment within the landfall facilities as water based extinguishing systems are not considered an effective measure to extinguish or even mitigate the effects of gas fires on gas containing equipment. Main piping will be installed underground as much as possible and ESD valves will be installed in pits to minimise exposure to fire and explosion events, and therefore minimise the potential for escalation. The containers housing the E&I equipment will be provided with automated gaseous extinguishing systems in accordance with applicable fire protection codes and standards. As the rooms in the containers will be occasionally occupied by electrical/instrumentation personnel, signs and warning systems shall be in place to ensure personnel do not enter or get trapped in the rooms when the system is activated upon fire detection. The containers Heating Ventilation Air Conditioning (HVAC) system will be provided with fire dampers, to be closed prior to activation of the extinguishing system. This will ensure the effectiveness of the extinguishing system and prevent migration of inert gas to other areas.

During a gas venting event (for example during a process shut down for maintenance) there is a risk that the gas cloud could ignite at the vent stack. If this occurs, the gas supply to the vent stack will be stopped.

Security Systems

The perimeter of the landfall facilities will be secured by chain-link fencing. An intrusion detection system with Closed-Circuit Television (CCTV) and presence detection will also be installed at the landfall facilities. The CCTV and presence detection will be monitored from the CCR. The CCR will also have a constant and secure communication link with operational staff located at the Russkaya CS (operated by Gazprom Invest) who will be alerted to an incident if necessary.

A Security Plan is currently being developed by South Stream Transport as part of the Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS). The Security Plan will define the detailed management and security measures to be employed for the Project. Further information on the management plans that will be produced for the Project is provided in Chapter 22 Environmental and Social Management.
5.2.5.8 Utilities

Electrical Power Supply

During operation, the landfall facilities will be provided with 400 kW of electrical power, provided via two 10 kV buried cables which will run from the Russkaya CS to the landfall facilities. Transformers will be provided within the landfall facilities to adjust the electricity supply as required for the operation of systems and equipment.

In addition, emergency power supply provisions are provided at the landfall facilities to support critical electrical systems following the loss of normal power supplies. It will be supplied by an emergency power generator and batteries (uninterruptible power supply). The emergency power generator is a diesel generator with integrated diesel storage for several days of power supply.

Emergency power is provided so that essential safety systems can still function and maintain safe conditions following the loss of normal power supplies. These systems are primarily those associated with control and monitoring, emergency shutdown, F&G detection systems and communication.

Water

There is no process water demand at the landfall facilities and there will be no service water connection to a mains supply. Potable water for domestic consumption will be provided through a drinking water dispenser or bottled water that will be brought in when required for personnel. Water is not required for firefighting.

Wastewater

No sewerage connection is required for the landfall facilities as chemical toilets will be used. Proprietary service will be contracted for toilet emptying for disposal off-site, and maintenance of chemical toilets. The only water collected during the Operational Phase will be rain water run-off from hardstanding areas.

The run-off will be guided via engineered sloped surfaces and a system of drainage channels which will flow towards the south-eastern corner of the landfall facilities. The collected water will be filtered by sand traps and pass through an oil-water separator before being discharged into the nearby gully, Graphova Gap, which is a tributary of the Sukko River.

Systems and equipment using liquid fuels or chemicals, for example the emergency back-up diesel generator, will be provided with impermeable bunding to contain any leaks/spills as an integral part of the design. Any rainwater drainage from these areas will be directed through an oil-water separator prior to being discharged.

Any waste water arising from operational maintenance activities (e.g. pigging of pipelines) will be collected on site in tanks and transported from site by an appropriately licensed waste hauler to an appropriate waste treatment site in accordance with current waste management regulations.
Waste

No waste will be produced at the landfall facilities during normal operating conditions as the landfall facilities will be unmanned. Low volumes of waste will be generated during maintenance activities (for example during pigging of the pipelines). This will be collected and taken-off site and disposed of at an appropriately licensed waste treatment site in accordance with current waste management regulations. A description of potential waste streams generated during the Operational Phase is provided in Chapter 18 Waste Management.

5.2.5.9 Telecommunication System

The landfall facilities will be equipped with a Telecommunication System (TCS). The TCS will be designed to operate under normal conditions with minimum operator actions required. As the distance between the landfall facilities in Bulgaria and the landfall facilities in Russia is in excess of 900 km, and the location of the CCR and BUCR in Amsterdam is also a significant distance from the landfall facilities, a dedicated South Stream Offshore Pipeline telecommunication network infrastructure (e.g. use of fibre optic cables) is not considered feasible.

It is proposed that a service with high availability in combination with high bandwidth is used. Thus a broadband internet connection (Digital Subscriber Line (DSL)) will be used as the primary transmission technique and data path for the TCS. A satellite connection (Very Small Aperture Terminal (VSAT)) will provide a backup transmission technique. The TCS will automatically switch back and forth between data paths, based on failure and recovery from failure of data paths. The landfall facilities will also be equipped with an Ultra High Frequency (UHF) radio system to enable two-way indoor and outdoor communication at the landfall facilities where no fixed telephone system is available. The mobile network (Global System for Mobile Communications (GSM)) will be used to supplement the telephone network but is not part of the TCS due to limited bandwidth.

Telecommunication links between the Project and the “Expansion of the United Gas Supply System” will be made via two buried fibre optic cables connecting the landfall facilities and Russkaya CS. The connection between the fibre optic cables installed by South Stream Transport and Gazprom Invest will be made at the Telemechanic Valve Station being developed by Gazprom Invest approximately 300 m upstream from the landfall facilities. The fibre optic cables will allow bi-directional information exchange to take place between the landfall facilities and Russkaya CS and wider South Stream Offshore Pipeline facilities such as the CCR in Amsterdam. Information to be exchanged includes safeguarding signals (e.g. if a shutdown is taking place), process control data (e.g. changes in flow rates, valves opening/closing) and security information (e.g. a security alert as a result of a security breach).

5.2.6 Design Philosophy

The South Stream Offshore Pipeline (including the Project) has a design life of 50 years. The overall design philosophy is to ensure that the South Stream Offshore Pipeline is in compliance with internationally recognised standards for the design, material use, fabrication, installation, testing, commissioning, operation and maintenance of pipeline systems. Furthermore, the design aims to minimise impacts to the environment and communities.
5.2.6.1 Pipeline System Design Codes and Standards

The Project will be undertaken in compliance with national and internationally recognised standards for the design, material use, fabrication, installation, testing, commissioning, operation and maintenance of pipeline systems. The Project will comply with Russian Federation national legislation, spatial planning (detailed development plans), investment design, construction permit and other related permits.

The Project will be designed in accordance with recognised and respected pipeline industry standards.

In addition, a Project Specific Design Code (PSDC) will be prepared for the Project, which is intended to reconcile the design with Russian requirements. The PSDC for the Project will be developed during the detailed design stage and will be primarily based on DNV-OS-F101 (2010).

DNV will certify that the offshore gas pipeline is compliant with its internationally-recognised offshore design code Offshore Standard DNV-OS-F101, which is harmonised with ISO 13623:2009 and other relevant ISO standards. This design code has been used for 65% of offshore pipelines worldwide, including Blue Stream, which connects Russia with Turkey across the Black Sea, and Nord Stream, which is the only high pressure offshore pipeline constructed in the Baltic Sea.

5.2.6.2 Pipeline Design Parameters and Gas Properties

System Export Capacity

When fully operational the Project will have a design export capacity of 63 Billion Cubic Meters (BCM) per year. Each of the four pipelines will have an export capacity of 15.75 BCM and a daily flow rate of approximately 47.9 Million Standard Cubic Metres (MMSCM) per day.

The entire South Stream Offshore Pipeline, including the Russian sector, will have a design pressure of 300 bar, although the expected maximum operating pressure is anticipated to be approximately 284 bar. The operating pressure of the South Stream Offshore Pipeline will vary across its length, particularly in relation to friction inside the pipelines and ambient temperature conditions surrounding the pipelines. The operating temperature of the gas will be approximately 50°C at the upstream end of the Project pipelines and will gradually fall as the gas moves further offshore through the pipeline. By the time the gas makes landfall in Bulgaria the arrival operating pressure will have fallen to between 65 and 87 bar (if the South Stream Offshore Pipeline is operating at maximum flow rate).

The operating temperature of the gas on arrival in Bulgaria will normally be approximately -5°C. However, during extreme winter conditions there is potential for the gas temperature to fall to -8°C and as such, the pipelines have been designed to a minimum temperature of -10°C.

The South Stream Offshore Pipeline operating data is summarised in Table 5.1.

Safety protection facilities will be provided so that the pipelines at the landfall facilities in Russia will not be subject to temperatures higher than the maximum design temperature. This is described in more detail in Section 5.6.1.

**Gas Composition and Properties**

The gas to be transported by the South Stream Offshore Pipeline will be treated to a dry condition (i.e. having a water and hydrocarbon dewpoint of -22°C at 65 bar). Dry gas means water, liquefiable hydrocarbons and other impurities have been removed from the gas to make it suitable for sale to gas customers. The gas will consist of approximately 97 mol% \(^2\) of methane and the maximum carbon dioxide (CO\(_2\)) content will be 0.41 mol%. The gas density is anticipated to vary between approximately 60 and 250 kilograms per cubic metre (kg/m\(^3\)).

\(^2\) Mol% describes the percentage of moles (or molecules) within a given mixture.
Table 5.2 provides a summary of the likely composition of the gas. These gas properties apply as design values only and the properties of the processed natural gas provided to the South Stream Offshore Pipeline may vary slightly from those identified in the table. However, any changes will be very small deviations around the design natural gas parameters and will not result in changes to the size and design of the main Project components.

**5.2.6.3 Pipeline Design Data**

**Pipeline Overview**

The pipelines will be constructed of steel line pipes made of 12 m long sections, which will be welded together. The pipe sections will be coated both inside and outside prior to delivery to the marshalling yards. The internal coating will be an epoxy paint which improves internal cleanliness and the operational gas flow rate, whilst the external coating will be made of three-layer-polypropylene (3LPP) to protect the pipelines from corrosion.

Shallow water sections of the subsea pipelines (for water depths of less than approximately 88 m, including buried pipelines) will be additionally coated with reinforced concrete to increase their weight to improve stability against sea currents and provide additional protection from external damage due to third party activities. The concrete coated pipelines will be delivered to the marshalling yards pre-coated ready for installation. In addition, the pipelines will be protected against corrosion by a cathodic protection system consisting of sacrificial anodes for the nearshore and offshore sections and an Impressed Current Cathodic Protection (ICCP) system for the landfall section.
Pipe Dimensional Data

The steel pipe properties and dimensional data of the 32-inch pipes to be used for the South Stream Offshore Pipeline (including the Project) are summarised in Table 5.3 and Table 5.4, respectively.

The pipe used for the landfall, nearshore and offshore sections will have the same dimensions and steel properties, with the exception of a short section within the landfall facilities. Within the landfall facilities, 24-inch (609.6 mm) outside diameter steel pipes will transport the gas from a 32-inch x 24-inch reducer to a 32-inch x 24-inch barred tee as described in Section 5.2.5 and illustrated in Figure 5.5.

5.2.6.4 Buckle Arrestors

Buckle arrestors (pipe reinforcement) are used in the pipeline to avoid buckle propagation in the event of local buckling by placing arrestors at regular intervals and/or in susceptible areas along
the length of the pipeline. The buckle arrestors will be welded into the pipelines in those areas that are susceptible to collapse, local buckling or propagation buckling.

Buckle arrestors are manufactured from the same steel grade as the pipes and basically act as a reinforcing ring placed around the outside of the pipe.

An integral ring buckle arrestor is considered to be the most effective type of arrestor for deep water pipeline projects. As such, an integral ring buckle arrestor approximately 4.1 m long with wall thickness of 74 mm (tapering down to 39 mm) is proposed. Buckle arrestors will be required in water depths in excess of approximately 650 m and it is proposed that a buckle arrestor spacing of 2,000 m is used. As the exact spacing of arrestors will depend on the pipelay installation methodology, the final spacing of the arrestors will be determined in consultation with the appointed installation contractor.

5.2.6.5 Welding

The line pipe sections will be welded together to form the four pipelines. Welding consumables (e.g. electrodes, wires and fluxes) that are similar and compatible to the composition of the line-pipe material will be used. The weld properties will have a minimum steel grade equal to that of the pipe. No other materials will be added during welding.

Each weld will be subject to visual inspection and non-destructive examination (NDE) to ensure the weld meets the required specification. The weld specification will be agreed with the installation contractor prior to construction and supported by an Engineering Critical Assessment. The weld specification will be produced to complement the NDE procedures.

Critical processes such as welding will be inspected by the contractor’s quality assurance crew, and thereafter inspected by representatives of the certification company and South Stream Transport.

Corrosion Protection, Internal and External Coatings Corrosion Protection System

The corrosion protection system of the pipelines is important to ensure pipeline integrity during installation and during its operational life. The principle of cathodic protection is to prevent anodic sites occurring on the structure under protection by allowing the anodic reactions to occur on specially designed and installed anodes.

An indicative schematic diagram of the onshore and offshore corrosion protection system is shown in Figure 5.6.
Cathodic Protection

**Landfall Section Pipelines**

An ICCP system will be installed to provide cathodic protection of the landfall section pipelines. With an ICCP system the current flow is “impressed” or forced by a power supply. The power source will deliver a direct current (DC) through the groundbed to provide the cathodic protection.

**Nearshore and Offshore Section Pipelines**

To ensure the integrity of the nearshore and offshore (subsea) pipelines over their operational life, secondary anticorrosion protection will be provided by sacrificial anodes. The cathodic protection design of the offshore pipeline is performed in accordance with the recommended practice design code DNV-RP-F103.

Applying the recommended practice design code (DNV-RP-F103) for the selected zinc anodes, results in the following anode requirement per pipeline in Russian waters as provided in Table 5.5. This assumes a maximum spacing of up to 300 m between anodes.

**Table 5.5 Estimated Number of Anodes Required per Offshore Pipeline (in Russian Waters)**

</tbody>
</table>
5.2.7 Resource Efficiency

Resource efficiency measures are included in the Construction Management Plans which will form part of South Stream Transport’s Environmental and Social Management Plan (ESMP). Examples of such measures in Russia include:

- Minimisation of plant, equipment and vehicle noise and air emissions;
- Contractor shall ensure that all vehicle engines are turned off when the vehicle is not in use. Where possible, equipment with engines shall not be left running at night;
- Minimisation of the volume of water generated by trench dewatering, the contractor shall minimise the time that trenches and pits are open;
- The contractor shall actively seek and implement opportunities to avoid, minimise, reuse or recycle waste materials;
- Surplus excavated spoil shall be used for landscaping purposes within the construction corridor or will be used for site engineering or restoration purposes at a local landfill site, or as inert backfill at identified quarries;
- Appropriate vessels will be chosen and maintained correctly; and
- Systematic monitoring of the condition and the adjustment of the fuel systems of ship equipment to ensure efficient use of fuel.

5.3 Construction Phase

This section describes the activities that will take place during construction of the Project. Activities are described for each section of the Project: offshore, nearshore and landfall.

5.3.1 Indicative Construction Schedule

The overall South Stream Offshore Pipeline phases and timeline is provided in Chapter 1 Introduction, and the construction schedule for the Project is summarised in Figure 5.7. The schedule presented in Figure 5.7 is the base case estimate that has been used for the planning of the Construction Phase and Pre-Commissioning Phase of the Project. Construction is scheduled to begin in 2014, with first gas from Pipeline #1 scheduled for late 2015, and all four pipelines fully operational by the end of 2017.

As with all large construction projects, there may be some changes made to the schedule during the Construction and Pre-Commissioning Phase as a result of unforeseen delays such as weather conditions, logistics problems, geological conditions/seabed intervention issues or administrative procedures with national Governments. Should there be any major change to the construction schedule, which may affect the results of the ESIA Report the management of change process described in Section 5.11 will be followed.

Each of the pipelines in the landfall section from the landfall facilities to the microtunnel entry shaft will be installed consecutively in a single construction period to minimise the length of disturbance. Restoration of the landfall and nearshore sections will not commence until successful pre-commissioning tests of these sections have been concluded.

</table>
The construction schedule presented in Figure 5.7 assumes the deep water part of the pipeline (water depth greater than 600 m) is laid by J-Lay method. However, S-Lay methods could also be used. Further information on J-Lay and S-Lay pipe-lay methods is provided in Section 5.3.5.5 and 5.3.6.4. The use of J-Lay provides a more conservative approach in terms of scheduling, as the J-Lay pipe-lay rate is typically slower than the S-Lay method.

The construction schedule assumes the installation of two or more of the pipelines in the deep water section (water depth >600 m) will overlap. To achieve this strategy, multiple pipe-lay vessels must be utilised during the course of the installation. Following this phasing concept, pipeline #1 and pipeline #2 are installed using the first pipe-lay vessel. Approximately midway through the pipe-lay of pipeline #2, a second pipe-lay vessel then commences with pipeline #3. Once the first pipe-lay vessel completes pipeline #2, it then commences with the pipe-lay of pipeline #4.

Installation of one pipeline (pipeline #3) is removed from the critical path installation sequence thus reducing the completion time of the offshore pipe-lay process by approximately one year. The use of a second pipe-lay vessel to perform simultaneous work can be introduced at various other points in the schedule to achieve the same results.

5.3.2 Logistics and Material Supply

The Project will require the procurement of materials, equipment and labour from locations in Russia, the EU and outside the EU. Established road, rail and sea transportation routes will be utilised during the Project. Preference will be given to source equipment (such as plant and construction vehicles) and materials which meet the required project specifications from Russia wherever possible. The pipe to be used for the installation of the Project pipelines is anticipated to come from pipe mills located in Europe, Russia, Japan, and/or India.

At the time of preparing this ESIA Report it is anticipated that all of the pipe required to construct the Project will arrive at marshalling yards in Bulgaria via sea.

5.3.2.1 Marshalling Yards in Bulgaria

Large scale pipeline construction work requires considerable support from onshore support facilities, known as marshalling yards, for the delivery, storage and load out of pipe, plant and equipment. The marshalling yards will also provide support facilities, which will provide general storage for supply of consumables to the offshore fleet, and managerial support for South Stream Transport and its contractors.

Marshalling yards for the Project will be located at the ports of Varna East, Varna West and Burgas in Bulgaria. The impacts of the development and use of these marshalling yards are assessed in the Bulgarian ESIA. The Project is committed to using these marshalling yards for construction of pipelines 1 and 2, including construction of the landfall (onshore) components in Russia and in Bulgaria. Once future construction contracts for pipelines 3 and 4 are signed, it will be known if the marshalling yards will remain in Bulgaria, or be moved to Russia. If the latter, then the management of change process, as described in Section 5.11, will be invoked and an impact assessment prepared if required.
5.3.2.2 Ports

Although it is anticipated that there will be no marshalling yards located on the Russian coast, it is likely that the contractor will use the Port of Novorossiysk for some of the activities listed below during the Construction Phase of the Project:

- Temporary storage of pipe;
- Load out of pipe to the landfall section construction spread via road transport;
- Receipt, temporary storage and load out of plant, equipment and supplies to the landfall section construction spread;
- Receipt of wastes from vessels generated during construction of the nearshore and offshore section construction spreads prior to onward transport to suitably licensed waste handling facilities;
- Base for the supply vessels necessary to deliver construction materials;
- Re-fuelling and maintenance of construction vessels and bilge-water disposal; and
- Base for crew-change vessels travelling to the nearshore and offshore construction spread.

Although the use of other Russian ports is possible, only Novorossiysk has been included in the assessment as it was not known at the time this ESIA report was prepared which other ports could be used, or which activities could be involved. If there is a need to examine the impacts of activities taking place at an alternative port, they will be considered by the management of change process described in Section 5.11.

5.3.3 Onshore Access Routes

5.3.3.1 Transport Routes from Novorossiysk Port

Pipe sections and other materials that are required for the installation of the landfall section of the Project will be delivered from the port of Novorossiysk to the landfall section construction sites by road. The proposed road delivery route from Novorossiysk will utilise the M25, as summarised below.

The delivery route from Novorossiysk will utilise the M25 and the Rassvet to Gai Kodzor Road. Construction traffic will then use a temporary road being constructed by Gazprom Invest to bypass Gai Kodzor before joining the Gai Kodzor to Varvarovka road briefly, and then turning off onto a new Varvarovka bypass road being constructed by South Stream Transport for use during the Construction Phase of the Project.

Permanent Access Roads

From the Varvarovka to Sukko Road, a new permanent access road (shown in red in Figure 5.8) will be constructed by Gazprom Invest, to support the development of the “Expansion of the United Gas Supply System”.

This permanent access road will be approximately 2.7 km in length, and only the last spur (of approximately 200 m shown in orange in Figure 5.8) will be constructed by South Stream.
Transport. This road will be utilised throughout the Operational Phase of the Project to provide access to the landfall facilities and pipeline RoWs.

A 2.6 km bypass road (referred to as the Varvarovka bypass road, shown in brown in Figure 5.8) will be constructed by South Stream Transport to bypass the town of Varvarovka and prevent construction traffic from passing through those residential settlements during the Construction Phase of the Project. Although the Project will make only temporary use of it, the road will be a permanent structure as local residents / motorists will continue to use it after construction is complete.

**Temporary Access Roads**

Temporary access roads will also be required during the Construction and Pre-Commissioning Phase of the Project.

**Temporary Bypass Road**

A temporary bypass road (shown by dashed pink lines in Figure 5.8) has been constructed by Gazprom Invest to avoid their construction traffic passing through residential settlements in Gai Kodzor. Although this bypass road is part of the “Expansion of the United Gas Supply System”, South Stream Transport will use the same temporary bypass road for construction of the Project.

**Other Temporary Access Roads**

A 0.8 km temporary access road (shown in purple in Figure 5.8) will be installed by South Stream Transport from the point where the Varvarovka bypass road meets the permanent access road being constructed by Gazprom Invest, and will travel south to the temporary Pipeline String Preparation Area (Site B). A temporary access road will also be established within the construction corridor shown in (Figure 5.8) to allow the movement of heavy equipment and materials. The temporary access roads will be removed following the completion of the Construction Phase. Access along the permanent RoW for inspection and maintenance activities will be via a minor track which will be accessible by 4x4 vehicles only. Further information on the construction of the access road and construction corridor road is provided in Section 5.3.4.2.

**5.3.3.2 Freshwater Supply**

Freshwater is required for the microtunnel construction process (approximately 37,000 m$^3$ in total) and the hydrotesting of the landfall facilities (approximately 500 m$^3$). In addition there will be an average usage of approximate 10 m$^3$ of water per day for general construction activities (domestic usages, dust suppression, wheel washing etc.) at the landfall section construction sites.
Water will be obtained from an existing well located on the northern side of Sukko. The route from the northern edge of Sukko to the landfall section is shown in Figure 5.8. However, water cannot be sourced from here between May and September (inclusive). Therefore, a large volume of water (up to 10,800 m³) may need to be stored within the landfall section construction sites during this period. Further information on water use and storage requirements is provided in Section 5.3.4.1.

5.3.3.3 Landfill, Waste Facility and Quarry Locations

Potential waste facilities, landfill sites and quarries to support the construction of the Project have been identified (see Figure 5.9). However, it should be noted that no agreements with these sites has been put in place and alternative sites may be identified during the detailed design phase of the Project. When suitable sites are confirmed, the potential impacts of traffic travelling between these sites and the landfall section construction site will be managed through the Russian Landfall Construction Management Plan (CMP), which will form part of South Stream Transport’s ESMP. The CMP will contain activity-specific requirements, to be met by both South Stream Transport and the appointed contractors (and sub-contractors). Further information on the Russian Landfall CMP and South Stream Transport’s ESMP are described in Chapter 22 Environmental and Social Management.

Figure 5.9 Locations of Potential Waste Facilities, Landfill Sites and Quarries
5.3.4  **Construction of Landfall Section**

The landfall section is approximately 4 km in length. Within this section, the pipelines will be buried using both open-cut and trenchless construction techniques and will pass through the landfall facilities. The pipelines will be buried using open-cut techniques for approximately 100 m from the connection to the “Expansion of the United Gas Supply System” to the landfall facilities and for approximately 2.4 km from the landfall facilities to the microtunnel entry shafts. Due to the presence of a steep sea cliff at the shore crossing, for the remaining 1.4 km the pipelines will be housed in microtunnels (2.5 m in diameter), which will terminate approximately 400 m from the coast in a water depth of approximately 23 m. The equipment within the landfall facilities is listed in Section 5.2 and illustrated in Figure 5.4.

Prior to construction, the appointed contractor will perform a pre-entry survey, including topographic and photographic records at all construction sites, and will prepare a Record of Condition in agreement with landowners, tenants and South Stream Transport. This record will be used as the standard against which the quality of the restoration work will be judged at any time during the construction works and upon completion of the works. Restoration of the land required for the temporary facilities during the Construction and Pre-Commissioning Phase is estimated to take approximately 17 months.

5.3.4.1  **Temporary Facilities**

A number of onshore temporary facilities will be required throughout the Construction and Pre-Commissioning Phase for the storage of pipe, equipment, materials, spoil storage areas, parking space and mess and welfare facilities for workers. Pipe will be temporarily stacked within the construction sites prior to transport to the construction spread for installation. A summary of the estimated areas of land required for these temporary facilities is shown in Table 5.6 and illustrated in Figure 5.10. It should be noted that these are the maximum extents of land anticipated as being required. During construction, the actual footprint of these areas will be reviewed by the contractors and South Stream Transport to ascertain if the footprints can be reduced to minimise the areas of land clearance required. Further information on the microtunnel construction site is provided in Section 5.3.4.5. The majority of this land will be rehabilitated following completion of construction.

* Continued...
The Microtunnel Construction Site (Site A), Pipeline String Preparation Area (Site B), Landfall Pipeline Construction Site (Site C), the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E), and the optional Transfer Site will have approximately 50% of their surface area to be reinforced with small stones/rock to prepare areas of hardstanding. This land will be re-instated following completion of construction.

A Transfer Site (shown indicatively in Figure 5.10) may be required as a temporary laydown area for equipment and materials required for the Project between the construction sites and the public highway. It may also be used to temporarily store soils excavated for the Project that cannot be re-used on site before they are taken away for disposal. Deliveries of materials and equipment to the temporary facilities will be made via the temporary and permanent access roads described in Section 5.3.3 and shown in Figure 5.8.

The layout of equipment within each construction site will be subject to the preference of the appointed contractor. However, it is anticipated that a number of pre-fabricated cabins and/or containers will be required to provide office space, mess and welfare facilities etc. in the Microtunnel Construction Site (Site A), the Landfall Pipeline Construction Site (Site C) and the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E). Pipe will be temporarily stacked within the Landfall Pipeline Construction Site (Site C), and potentially at the optional Transfer Site, prior to transport to the construction spread for installation. Due to the source of freshwater near Sukko being unavailable for supply during May to September (inclusive), a large volume of water (up to 10,000 m$^3$) may need to be stored in large water tanks. This water is required for the microtunnelling process, but it is assumed that it would be stored in the Pipeline String Preparation Area (Site B), so that it is adjacent to the Microtunnel Construction Site (Site A). Approximately 1,000 m$^3$ may also need to be stored at the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E). This water is required for general construction activities at the various onshore construction sites. The exact location and dimensions of the storage tanks will be finalised during the detailed design and will be agreed between the Contractor, South Stream Transport and the relevant Local Authorities.

It is anticipated that during March and April 2014 seven months’ supply of water (approximately 1,400 m$^3$) will be delivered to site for general construction activities. Between October 2014 and April 2015 (inclusive), approximately 28,500 m$^3$ of water will be delivered to the Pipeline String.

* 21.72 ha of the Permanent RoW is located within the Landfall Section Pipeline Construction Corridor, therefore the temporary landtake requirement outside the RoW is 5.71 ha.
† 4.93 ha of Site A is located within the Landfall Section Pipeline Construction Corridor, therefore the temporary landtake outside the Landfall Section Pipeline Construction Corridor is 3.83 ha.

**Complete.**

---
Preparation Area (Site B) and 2,900 m³ (2,400 m³ for general construction activities and 500 m³ for hydrotesting) to the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E). Between October 2015 and mid-February 2016 (inclusive) a further 8,500 m³ will be delivered to the Pipeline String Preparation Area (Site B) and 900 m³ will be delivered to the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E). It is considered that the amounts of water required at the construction sites after mid-February 2016 will be sufficiently low that associated truck movements will be negligible and do not need to be considered. The only activity after this date is site reinstatement. The estimated truck movements to bring freshwater to the site have been included in Table 5.13 These numbers are also specified in Appendix 9.1 Traffic and Transport Study.

A temporary construction corridor will be required along the length of the landfall section pipelines route from the tie-in location with the project “Expansion of the United Gas Supply System” to the landfall facilities, and from the landfall facilities to the microtunnel entry shaft. It should be noted that some of the permanent facilities described in Section 5.6.6 and shown in Table 5.4 are located within the footprint of the boundary of the temporary facilities shown in Table 5.7. This includes the permanent RoW which is located within the construction corridor. A temporary security fence will be installed around the perimeter of the temporary facilities, and the landfall facilities site during construction to prevent the entry of unauthorised persons. Signs will be erected to raise awareness of the hazards. Fencing may also be provided where necessary to prevent the entry of animals. Further information on requirements for fencing along the construction corridor is provided in Section 5.3.4.5 and fencing in relation to the prevention of injury to animals is provided in Chapter 11 Terrestrial Ecology.

All open-cut pipeline construction activities will be undertaken within a temporary construction corridor. The construction corridor will nominally be 120 m wide. A typical cross-section of the construction corridor is shown in Figure 5.11.

Figure 5.11 Typical Construction Corridor
5.3.4.2 Construction of Permanent and Temporary Access Roads

The Project will require the construction of the following roads, as shown in Figure 5.10 to provide access to all aspects of the Project during construction of the pipelines, microtunnels and landfall facilities:

- Approximately 200 m of permanent access road that will branch off the permanent access road being constructed by Gazprom Invest (shown in red in Figure 5.10) to meet the southern edge of the landfall facilities (shown in orange in Figure 5.10). This road will have a running surface approximately 7 m wide with 1.5 m wide shoulders on either side of the road, and will require an additional 3.5 m either side of the road edge during construction of the road only. This entire road will be contained within the area designated for cut and fill slopes, therefore the road does not add to the total permanent or temporary land take of the Project;

- Approximately 0.8 km of temporary access road from the permanent access road being constructed by Gazprom Invest to the temporary Pipeline String Preparation Area (Site B) (shown in purple in Figure 5.10). This road will have a running surface approximately 7 m wide with 1.5 m wide shoulders on either side of the road, and will require an additional 3.5 m either side of the road edge during construction;

- Approximately 2.6 km of access road (shown in brown in Figure 5.10 from the Gai Kodzor - Varvarovka Road to the permanent access road being constructed by Gazprom Invest. This permanent road is referred to as the Varvarovka bypass road and will be used by the Project during the Construction Phase only. This road will have a running surface approximately 8 m wide and 1 m wide shoulders on either side of the road. Due to the road being constructed on a slope, it is assumed that this road will require construction areas ranging from approximately 5 - 14 m at the road edges in some sections during construction to form safe slopes and the construction of retaining walls where required; and

Approximately 2.5 km of temporary access road (shown in Figure 5.10) within the temporary construction areas and along the construction corridor, which runs from the landfall facilities to the microtunnel construction site. This road will have a running surface approximately 4 - 5 m wide.

Road Construction Techniques

Where possible, a ‘cut-track’ design will be used for the construction of the permanent access road and temporary access roads, in which the topsoil will be stripped to expose a suitable rock or sub-soil horizon on which to build the track. The upper soil horizon will be suitably stored on the site for later reinstatement, as appropriate. Where practicable, a geotextile material such as a geogrid (grid-like mesh formed of plastics which provide ground stabilisation and reduce aggregate requirements) will then be placed to provide separation between the fill material and the founding strata. The road will then be built up on the geogrid by laying and compacting crushed rock. The actual depth will be dependent on ground conditions and topography and confirmed during the detailed design stage.
The temporary Varvarovka Bypass Road will be constructed on a hill slope and will require cuts and fills of soils in various sections of the road to form a suitable road surface. The road will also require a number of engineered slopes and retaining walls to ensure the integrity of the road is protected during its use throughout the Construction Phase.

In areas of very poor soil conditions, (i.e. boggy or wet ground) along the route of the temporary access road within the construction corridor, topsoil stripping may be omitted in favour of the geotextile material being laid directly over the ground. Alternatively, there may be sections which are constructed with timber crane / bog mats which can be easily removed following the completion of the construction process. Timber crane / bog mats provide stable access over boggy and wet ground conditions, reducing permanent damage to existing surfaces by spreading heavy loading, increasing stability and minimising hard surface damage.

As far as possible, the access roads will be constructed of material from locally sourced imported graded stone and geotextiles. The source of this material is yet to be confirmed but a potential suitable quarry source has been identified (see Figure 5.9).

However, it should be noted that no supply agreement with this source has been put in place and alternative sources may be identified during the detailed design phase of the Project. When a suitable source is confirmed, the potential impacts of traffic travelling between the quarry and the landfall section construction site will be managed through the Russian Landfall CMP, which will form part of South Stream Transport’s ESMP. The CMP will contain activity-specific requirements, to be met by both South Stream Transport and the appointed contractors (and sub-contractors). Further information on the Russian Landfall CMP and South Stream Transport's ESMP are described in Chapter 22 Environmental and Social Management.

The materials imported from quarries will be chemically checked to ensure their inertness and to prevent any potential adverse effect on groundwater. The permanent access road leading to the landfall facilities will be finished with an asphalt concrete or tarmac surface approximately 80 mm thick.

For the purposes of the ESIA it has been assumed that the entire length of the temporary access road from the junction with the permanent access road to the temporary Pipeline String Preparation Area (Site B) and the temporary road within the construction corridor will be constructed with rock, although some sections may use timber crane/bog mats.

**Road Drainage**

The general approach to road drainage is described below, along with measures specific to the Varvarovka Bypass Road.

Road edge drains will be led away by ditches into drainage swales (a shaped and sloped depression in the soil surface) via settlement lagoons and small ponds away from the road edges so that runoff is controlled to prevent sediment entering local surface waters. Swales are shallow channels that are used to collect and/or move water and also remove pollution from it (see Chapter 8 Soils, Groundwater and Surface Waters). They can be covered by grass or other vegetation and have shallow side slopes. Swales allow the water to infiltrate into the ground resulting in less water run-off. The road will have adequate cross-fall to allow rainwater to be shed and, where gradients are present, lateral drains will intercept flow along the road. A
drainage ditch may be formed on the upslope side of the road where required to collect runoff from the upper slopes, dependent on detailed drainage design.

Cross pipes will be laid as required to permit good road drainage and introduced where the position of the road may cause ponding to one side. As far as possible, these will coincide with naturally occurring drainage channels. Where the road slopes downhill, ‘waterbars’ will be placed to divert the flow into naturally occurring channels. The key function of a waterbar is to divert running surface water off a sloping road surface to prevent the road surface from being scoured by the water flow and becoming rough and gullied and unsuitable for construction traffic.

Due to the steepness of the slope on which the Varvarovka bypass road will be constructed, this road will include some additional rainwater drainage features to those described above to ensure safe driving conditions during rainfall. The drainage features for this road consists mainly of ditches situated at the bottom of the road embankment (road edge) or at the head of surrounding slopes to collect water coming from the road itself and/or surrounding areas. In addition, in cut sections of the road a concrete lined ditch will be located at each side of the road to collect the water coming from the road surface and surrounding slopes. Where retaining walls are provided, to avoid water (from the surrounding slopes) flowing down the wall into the road, a concrete channel will be formed above the wall to collect the water. To avoid scouring of the concrete lined ditch, due to high flow velocity of water in areas of slopes greater than 5%, the lined concrete ditches will be provided with features to slow down the conveyed water.

**Road Crossings**

The permanent access road to the landfall facilities and temporary access road within the construction corridor will cross the unnamed tributary of the Sukko River which is located in the Graphova Gap (illustrated in Figure 5.10). This unnamed tributary has no or low flow during the summer months and more significant flow during the winter months.

A road crossing of the Graphova Gap within the construction corridor is necessary to allow the movement of construction vehicles and equipment. This crossing will remain in place to allow 4x4 vehicles to access along the permanent RoW during the operational phase of the project to allow for inspections of the pipelines. The design of the crossing will be finalised during the detailed design stage and will ensure that water flow is not impeded.

At the time of preparing this ESIA Report, the actual location of the temporary access road within the construction corridor is unknown and will be subject to the detailed design of the appointed installation contractor and approvals from South Stream Transport and/or the Russian Federation regulatory authorities.

During construction of the landfall section, the movements of construction vehicles will be restricted to the temporary construction yards, the construction corridor and the access roads constructed as part of the Project.

**Landfall Section Construction Plant, Vehicles and Equipment**

Table 5.7 presents a preliminary list of typical construction equipment that may be used during the construction of the landfall facilities and the installation of the open-cut pipelines.

Equipment specific to the construction of the microtunnels is provided in Table 5.9. There will be considerable transportation of labour, heavy equipment and materials on local roads for the delivery of pipe and heavy equipment from the supply port. The delivery route to the landfall section is described in Section 5.3.3.

The estimated total number of vehicle movements associated with the construction of the landfall section on the public road network is presented in Table 5.8.

**Figure 5.12 Average Daily Vehicle 2-Way Trips Movements to/from the Landfall Section during Construction**
The table presents total 2-way vehicle trips. A 2-way trip is defined as both the arrival and departure of vehicles to and from the site and therefore comprises two additional traffic flow movements over a day (inbound and outbound direction). Weekly construction traffic movements are anticipated to peak in the second half of 2014 (Figure 5.12). Existing traffic flows on the local road network are described within Appendix 9.1 Traffic and Transport Study.

It is anticipated that the Project will share this delivery route with construction traffic associated with the construction of the Russkaya CS. The potential cumulative impacts generated by both projects are described in Chapter 20 Cumulative Impact Assessment, including traffic generated impacts.

5.3.4.3  Landfall Facilities Construction

The construction of the landfall facilities is expected to last approximately 19 months (May 2014 to December 2015). The equipment, materials and offices, etc. required for the construction of the landfall facilities will be located in the Landfall Facilities Construction Site and Pre-Commissioning Spread/Commissioning Spread (Site E) shown in Figure 5.10 and Table 5.7 and described in Section 5.3.4.1.

The following works will be undertaken during construction of the landfall facilities:

- Preparatory works, including surveying, site clearance and earthworks;
- Construction of internal roads;
- Preparation of foundations;
- Erection of equipment;
- Piping and mechanical works, including NDE of all welds;
- Laying of cables and electrical works;
- Installation of operational and instrumentation control systems;
- Connection to utilities (electricity); and
- Reinstatement of temporary areas that are not part of the permanent project footprint.

Preparatory works will include preparation of access to the landfall facilities site, site clearing, site levelling (including cut and fill of the site) and erection of perimeter fencing and access gates.

The preparation of the site for the construction of the landfall facilities will require extensive earthworks in order to prepare a level area and to stabilise the slopes surrounding the landfall facilities. It is estimated that approximately 257,000 m$^3$ of material will be cut from the site and 134,000 m$^3$ of fill material will be required to form a level site for the landfall facilities. Due to the structural properties of the soils at the landfall facilities not being suitable for engineering purposes, it is anticipated that all of the cut material will be taken offsite for disposal and the entire quantity of fill materials will be imported to the site.

The levelled platform area will have both upward and downward slopes. Engineered slopes are required to stabilise the platform and ensure that the landfall facilities will not be at risk from
landsides from the surrounding hill slopes during its operational life. The design of the slope stabilisation techniques will be undertaken during detailed design, however the methods that may be considered to provide the necessary stabilisation include:

- Engineered structures;
- Vegetation stabilisation; and
- Soil bio-engineering systems.

In addition to earthwork, civil and structural engineering activities include excavation of foundations, surfacing of internal roads, car parking and paths, pouring of concrete foundations and slabs for pre-fabricated containers, foundations for equipment, vent stack, valve pits, erection of steel structures in the form of pipe bearings, supporting structures etc.

Fitting and connection of all communication equipment will allow the landfall facilities to be controlled locally from the containers containing the E&I equipment, and remotely from the CCR and BUCR in Amsterdam.

5.3.4.4 Pipeline Construction

General Overview

The landfall section of the Project will use a combination of open-cut and trenchless techniques for pipeline construction.

Conventional open-cut trenching techniques will be adopted for the installation of the four pipelines from the tie-in to the “Expansion of the United Gas Supply System” to the landfall facilities and from the landfall facilities to the microtunnel entry shafts. The four pipelines will be constructed one pipe at a time, although all four pipelines will be laid in one continuous construction period over a period of approximately six months to avoid the impacts associated with four separate construction periods. There will be a separation distance of approximately 19 m between the centreline of each pipeline.

Where the pipeline alignment will cross the shore there is a sea cliff with an average slope of approximately 43%, starting at sea level and rising to a height of approximately 150 m. The landward side of the coastal ridge has with an average slope of approximately 20% and drops down to a height of approximately 40 m above sea level at the microtunnel entry shaft location. Due to the steepness of the slope and the presence of rock, open-cut installation of the onshore pipeline across the sea cliffs is not feasible. The trenchless technique of microtunnelling has therefore been selected as the construction technique in this area. Each pipeline will be housed within one of four microtunnels each approximately 1.4 km long, which extend from an onshore entry shaft to approximately 400 m offshore at a microtunnel exit pit located within the nearshore section.

The alignment of the landfall section pipelines crosses one major road and two watercourses. The Varvarovka to Sukko road and the Shingar River are both crossed only by the surface trace of the microtunnels and thus impacts and disruptions are not anticipated during construction. The pipelines will directly intersect an unnamed tributary of the Sukko River that is located in
the Graphova Gap (illustrated in Figure 5.10). This watercourse will be crossed using open-cut techniques as described below.

The landfall section pipelines will also pass through the southern branch of the Marfovsky Fault. The exact location of the fault is subject to further geophysical survey, however the anticipated location based on survey work carried out to date is shown in Figure 5.10. The fault will be crossed using traditional open-cut techniques as described below and further information on the characteristics of the fault are provided in Chapter 7 Physical and Geophysical Environment.

**Open-Cut Pipeline Construction**

The general process for open-cut technique is shown in Figure 5.13 Typical Open-Cut Pipeline Construction Technique and summarised in the following sections.

**Figure 5.13 Typical Open-Cut Pipeline Construction Technique**

**Part 1**

**Part 2**

**Part 3**
Construction Corridor Preparation

The exact route of each pipeline will be surveyed and the centreline will be marked out. The temporary 120 m wide construction corridor will be clearly marked using wooden pegs. The edge of the construction corridor will require temporary fencing to prevent injury to animals, in particular the tortoise (*Testudo graeca nikolskii*), which is listed as critically endangered in both the International United Conservation Network (IUCN) Red Data List (Ref. 5.4) and Russian Federation Red Data Book (Ref. 5.5), and as Vulnerable in the Red Data Book of the Krasnodar Krai region (Ref. 5.6). Further information on methods to mitigate impacts on tortoises is provided in Chapter 11 Terrestrial Ecology. Environmental and archaeological specialists (appointed by the contractor) will accompany the survey crews to clearly mark sensitive environmental and archaeological sites.

Existing infrastructure that intersects the Pipeline route, such as walls, fences and paths, will be disturbed as little as possible. Existing third party services will be located, marked, and either safeguarded or diverted in accordance with owners agreements and relevant permits. It is known that the pipelines will cross beneath an underground communication cable and below a 10 kV overhead power line suspended on poles, approximately 850 m downstream from the landfall facilities.

For buried services, at the time of setting out the works, the contractor shall locate them and record depth, type and size through the use of hand excavation. All services will be adequately protected from damage by the laying of excavator mats, or geotextile membrane and hardcore and by maintaining a minimum separation distance of 1.5 m between the pipeline and existing services. Supporting spans will also be implemented to support the services if necessary. Alternatively, in agreement with the cable owner, it may be decided to cut and reroute the cable. The final decision will be subject to consultation with the cable owner and detailed design studies.

Due to the height the overhead power line is suspended over the access road and construction corridor it is possible that this may restrict certain types of vehicle from accessing the route. In order to overcome this and to maintain a safe working environment, the power will need to be cut (temporarily) and either an alternative power system provided or the power lines rerouted so that the construction equipment can travel safely along the route. A decision on which option will be selected will be based on consultation and agreement with the owners, local authorities and any other effected parties. South Stream Transport will put in place measures to ensure that disruptions to power supply are kept to a minimum.

During any works near the overhead power line, the contractor shall use extreme care to prevent contact between personnel and equipment and the power line. Clear warning signs detailing the working height and nature of the danger will be displayed either side of the overhead power line and the danger will also be explained to workers on site during safety toolbox talks.

In the event that unknown services are encountered, work will stop in this area until the nature of the services and owners have been established. Where diversions are necessary, works will be carried out in consultation with the owners. Clear warning signs will be erected for overhead cables, and temporary crossing points will be clearly marked.
Topsoil Stripping and Vegetation Removal

Prior to topsoil removal, any rare plant species (for example juniper (*Juniperus sp.*), a species listed in the IUCN Red Data List (Ref. 5.4), Red Data Book of the Russian Federation (Ref. 5.5) and Krasnodar Krai region (Ref. 5.6) will be translocated to suitable alternative habitat outside the construction corridor. Other notable species will be gathered in sufficient numbers to be used for the reinstatement work after the pipeline has been laid. In addition, the construction corridor includes areas of protected forests under the Forest Code of the Russian Federation. Tree species which are not to be translocated, and are of commercial value, will be harvested and extracted by conventional methods and standard forestry equipment. Clearance of immature or unmerchantable crops will be by use of scrub cutters or chainsaws with the resulting material being stored on site. South Stream Transport will consult with relevant land owners and the Russian Federation State Forestry Fund on the potential uses for the timber. During the Construction Phase, the requirement to strip the entire construction corridor will be reviewed by the contractor and South Stream Transport to ascertain if the area of topsoil stripping can be reduced. Further information on the habitats along the construction corridor and which species will be translocated is provided in Chapter 11 Terrestrial Ecology.

The topsoil will generally be stripped across the construction corridor and then stored to be used when reinstating the construction corridor. The topsoil stockpile will be typically no higher than 2 m to prevent degradation of the soil, and will be kept free from disturbance to reduce the possibility of physical damage and compaction. The careful storage of the topsoil is essential to protect the natural seed bank contained within the topsoil, which will aid the re-vegetation of the construction corridor during reinstatement works.

Some areas of the construction corridor may also be benched or graded to enable safe working, using typical construction site machinery to eliminate irregularities, large stones, tree stumps and other features.

Trenching

Each pipeline will be installed in separate, parallel trenches to achieve a centre line separation distance of approximately 19 m. The trenches will be excavated using mechanical excavators straddling or running alongside the pipeline trench. It is anticipated that some short sections of the pipeline route may encounter rock at trenching depth. Rock in such areas could be excavated by first fracturing it by mechanical means, typically a rock hammer attachment for an excavator. In the case of a large section of rock being encountered, the use of a chain trencher could be considered. Drilling and blasting of rocky sections of the pipeline route is not expected.

The open-cut pipeline trenches will be dug to a minimum depth of 2.5 m to allow for a minimum reinstated cover of 1.5 m. However, given local topography, the trench depth varies between 2.5 m and 4.5 m in order to minimise the amount of bends in the pipeline. Each trench will have a top of trench width of approximately 7 m, a trench bottom width of approximately 1.5 m and side slope angle of 45 degrees. The material excavated from the trenches (trench spoil) will be stored separately from the topsoil to prevent mixing of subsoil and topsoil that might hamper successful reinstatement.
At times it may be necessary to dewater the open-cut trench as a result of groundwater infiltration to the trench, surface run-off which has entered the trench, or directly from rainfall, although this is considered unlikely. Prior to such an activity commencing, schemes will be developed on an area by area basis. It is likely that if required, a soakaway (i.e. a pit filled with gravel or small stones) will be prepared within the construction corridor and the water will be pumped from the trench to the soakaway where it will slowly soak into the ground.

**Pipe Delivery, Stringing and Bending**

The 12 m pipe sections will be transported to the construction spread from the landfall pipeline construction site where the pipe sections are stored. The pipe sections will be transported along the construction corridor using stringing trucks and tracked vehicles. All pipes will arrive in a pre-coated condition (externally with 3LPP anti-corrosion coating and internally with an epoxy flow coating). Known commonly as ‘stringing’, the pipe sections will be placed end to end alongside the trench in preparation for welding. The pipe sections will be stored at least 100 mm above ground on timbers with padding and wedges.

In cases where there are significant changes in direction or elevation along the pipeline route (for example the crossing of the Graphova Gap), pipe sections with factory-manufactured bends will be installed. Final requirements for bending will be confirmed prior to pipeline installation. Where there are minor changes in elevation or direction along the pipeline route, cold bending of the pipeline will be undertaken by a bending crew. The bending crew will use a hydraulic bending machine to put gradual bends in the pipe. This equipment bends individual pipe sections to the desired angle at locations where there are changes in the natural ground contours, or where the pipeline route changes direction.

**Welding, Testing and Joint Coating**

The landfall section pipe ends will be bevelled in accordance with approved welding procedures using a pipe facing machine system to create a profile for welding, which will produce metal scraps (see Figure 5.14). The pipe sections will then be aligned and welded together using automatic, semi-automatic or manual welding equipment that travels along the length of the pipeline. The process is carried out inside a mobile shelter (see Figure 5.15) that covers the pipe section that is being welded and the people carrying out the work, thereby controlling the environment under which the weld is made. During welding, flux will be added to prevent oxidation of the base and filler materials. Metal scraps from bevelling and weld flux will be collected and stored in containers in the temporary construction sites before being collected by licensed waste hauliers for disposal.

Once welded, the welds will be subject to visual inspection and NDE, and the weld approved before a coating is applied to the welds on site. Any welds not meeting the required specification will be removed by cutting out a cylinder of pipe containing the weld and the pipeline re-welded and subject to full NDE.

After the welds have been checked, tested and approved, the coating crew will clean the exposed steel section at the joint between the pipes, sand-blast the steel, and apply a protective coating to it. The coating will consist of polyethylene HSS around the pipe (Figure 5.16).
Figure 5.14 Pipe Bevelling

Figure 5.15 Pipe Welding Shelter
Pipe Lowering and Backfilling

Following inspection of the weld coatings, the pipeline will be carefully lowered into the trench in a continuous operation with the aid of side booms (Figure 5.17). The pipeline trench will be backfilled in the reverse order to which it was excavated. The backfill will consist of fine grained granular material, mechanically sieved and well graded with a maximum particle size of 6 mm and will contain no sharp edges or deleterious matter.

The backfill material will be obtained, as far as practicable, using the same trench spoil that was taken from the trench originally. In rocky or uneven ground where the potential for pipe coating damage exists, the trench bottom will be given a protective 200 mm bed of soft earth or sand backfill material. Approximately 40,000 tonnes of imported material may be required to backfill the four pipeline trenches.

Backfill will normally be placed over the pipeline immediately after the pipeline has been lowered into the trench in order to protect the pipeline coating and to stabilise the open trench. The backfill is carefully compacted around and over the pipeline up to the top of the trench. Extreme care will be taken with the initial fill to avoid damage to the coating. During the burial process, a brightly coloured plastic warning tape will also be installed above the pipelines, along the entire length of the trench to provide warning in the event of future excavations in the area.

It will not be possible to return all the originally excavated trench spoil due to the volume of space taken up by the installed pipelines and removal of rock and other unsuitable backfill
material, etc. It is estimated that up to 45,000 m\(^3\) of surplus spoil will be left over from the installation of the four pipelines. Therefore, some will need to be either disposed of or incorporated into landscaping initiatives. Any surplus or unsuitable backfilling material (such as inert waste) will be removed from site and disposed of at an approved waste handling facility in accordance with applicable waste management regulations.

**Reinstatement**

After completion of pre-commissioning tests of the landfall and nearshore section pipelines (Section 5.4), the restoration of the construction corridor will begin. All affected areas along the construction corridor will be reinstated and restored as far as reasonably practicable to the original landform and condition. The removed topsoil will be placed back on the construction corridor. The original contours of the land will be restored as closely as possible; the topsoil will be stone picked and cultivated to enhance re-vegetation of the area.

Particular care will be taken to ensure that land drainage infrastructure, access roads and other networks and facilities disturbed / moved during construction, will be reinstated to their former state or replaced by a better quality system. Photographic records will be made of the route, where necessary, before and after the works to document any changes.

**Figure 5.17 Pipe Lowering into Trench**

![Image of Pipe Lowering into Trench](image-url)
The use of the stored topsoil (which preserves the natural seed bank and natural soil materials) will encourage natural processes and natural re-vegetation using only native plant species found on the site, thus conserving genetic biodiversity and composition of the original plant communities. Re-planting will take into account the requirements to protect the pipeline from deep-rooted vegetation.

Translocation of species of conservation concern gathered from the construction corridor before the start of the construction work will be undertaken in suitable locations where appropriate. Translocation will be undertaken in accordance with the requirements of the relevant Russian Federation authority and South Stream Transport environmental specialists. There will also be the opportunity to replant trees along the construction corridor outside the permanent 95 m wide RoW, which must be kept clear of deep rooted vegetation such as trees.

After re-instatement, the area will be monitored and maintained, as required, until normal growth patterns are re-established and confirmed by South Stream Transport’s environmental specialists in accordance with requirements set out in South Stream Transport’s activity-specific Russian Landfall CMP and overarching CMP - Biodiversity Management Plan. Details of the CMPs to be produced are described in Chapter 22 Environmental and Social Management. Further information on habitat reinstatement is provided in Chapter 11 Terrestrial Ecology, including provision for the replanting of areas outside the permanent 95 m wide RoW with trees.

**Pipeline Markers**

After re-instatement, the only visible evidence of the pipeline will be the RoW and pipeline and aerial markers placed along the route of each pipeline for future monitoring and line walking purposes. Each marker will have line of sight to its previous and following marker. A marker will also be installed wherever there is a change of direction.

**Crossing of the Graphova Gap**

Only one watercourse is crossed by the open-cut pipelines, an unnamed tributary of the Sukko River which is located in the Graphova Gap. This unnamed tributary has no or low flow during the summer months and more significant flow during the winter months. The Graphova Gap is approximately 15 m deep with slopes of up to 30 degrees.

If possible, the crossing will be undertaken during periods of low rainfall to minimise the potential for pollution and minimise the need for the installation of flume pipes or channel diversion, which may be required to maintain water flow during periods of heavy rain. Suitable mitigation measures to maintain flow and minimise transport of sediments will be undertaken as required in accordance with the Russian Landfall CMP. The location of the Graphova Gap can be seen in Figure 5.10.

The watercourse will be crossed using open-cut techniques. For each of the four pipelines crossing the gap, a dedicated trench will be excavated perpendicular to the watercourse, such that the top of pipeline will be approximately 1.5 - 2 m below the bed of the watercourse. The bottom of the trench will be approximately 2 - 3 m wide, with side slopes of approximately 45 degrees. Excavation of the pipeline trenches can be performed using standard hydraulic
excavators and the pipeline will be installed conventionally using standard pipe-laying equipment. During installation some pipe sections will undergo cold bending to ensure the pipeline follows the contours of the watercourse crossing.

After installation of the pipeline in the trench, protective measures will be installed to prevent possible flash floods from eroding the bed of the watercourse and exposing the external coating of the pipeline. This protection can be achieved by installing a pre-cast concrete slab (approximately 1.2 m wide and 0.15 m thick) and suitable engineering backfill, i.e. graded material on top of the pipeline with boulders placed above to prevent erosion, prior to general backfilling. An indicative design of the watercourse crossing is shown in Figure 5.18.

A detailed design of the crossing will be prepared by the appointed contractor prior to pipeline installation, for approval by South Stream Transport.

Following backfilling of the trench the crossing will be reinstated. However, due to the steepness of the existing gully slope, the reinstated slope profile will have to undergo some excavation and grading works to ensure the slopes remain stable during the Operational Phase of the Project so as to reduce the risk of damage to the pipelines and also to allow safe access for inspection purposes.

A number of techniques exist that could be used to stabilise the slopes. A possible solution is the use of geotextiles. Geotextiles are installed in layers between layers of fill material. After every layer of fill (about 0.5 to 1.0 m, depending on the quality of the fill material and angle and height of the slope) a geotextile blanket will be added and wrapped around the subsequent layer of fill. In this way, the stability of the slopes is significantly increased. The surface of the slope will be covered with a thin layer of topsoil.

To prevent erosion of the topsoil a special erosion-control geotextile mat will be installed. This geotextile mat, with an open structure, reinforces the upper 1 to 2 cm of the topsoil, and prevents surface erosion on the slope and supports the growth of vegetation such as grass or small bushes.

All temporary works will then be removed in a controlled manner so as to minimise sediment disturbance. A detailed design of the crossing will be prepared by the appointed contractor during the detailed design phase prior to pipeline installation. The design will ensure that the watercourse will be fully functional following reinstatement. Although it is not anticipated that there will be water present in the watercourse during construction, silt fences and/or other suitable measures (i.e. sediment entrapment matting or straw bales) will be located along and adjacent to this watercourse as required.

**Crossing of the Marfovsky Fault**

The landfall section pipelines will pass through the Marfovsky Fault as shown in Figure 5.10. The fault will be crossed using traditional open-cut techniques. However, to minimise the effect of potential displacement from seismic activity, each pipeline will be laid in an enlarged trench approximately 200 m long that will have a bottom trench width approximately 5 m wide.

The depth of the excavated trench shall be at least 3 m below the lowest point of the pipeline and the cover depth above the top of the pipeline will be approximately 1.5 m. The pipelines in
the fault section will be laid on a bed of sand and backfilled with loose sand rather than the previously excavated soils. The combination of the wider trench and backfilling with loose sand allows the pipelines to move in a lateral direction should there be any movement by the fault, thereby lowering the risk of damage to pipeline integrity.

**Crossing of Dirt Roads**

Multiple dirt roads associated with agricultural activities are crossed by the pipelines, for which the open-cut construction methods described above are considered suitable. Landowners will be consulted by South Stream Transport to inform them of temporary road closures. Measures, such as creating detours or phasing road closures, will be implemented to minimise nuisance to agricultural traffic.

**Microtunnel Construction Site Requirements**

The construction of the microtunnels will require a construction site of approximately 8.76 ha as shown Figure 5.10. The microtunnel construction site will contain all the plant and equipment required for construction of the microtunnels and will also include the location of the four microtunnel entry shafts. A typical layout of the microtunnel construction site is shown in Figure 5.19.

It should be noted that the final layout (within the defined area) will be subject to the preference of the appointed microtunnel installation contractor. For the purposes of this ESIA Report, it is anticipated that the microtunnels will be constructed one after the other, with only one tunnel boring machine (TBM) in operation at once. The microtunnel construction site will be in operation for approximately two years (includes from site preparation to completion of reinstatement work). However, the appointed microtunnel installation contractor may choose to start microtunnelling a second tunnel before the first is complete, which would reduce the construction period.

**Microtunnel Construction Method**

Microtunnelling is a trenchless construction method used to excavate underground tunnels. The microtunnelling method involves pushing pre-cast concrete jacking pipes (pipes designed to be driven through the soil to line and stabilise the pipe tunnel) behind a steerable, remotely controlled TBM from an entry shaft to an exit pit. On completion of the microtunnel, the pipelines are installed within the microtunnel by pulling the welded pipeline string through the microtunnel. The total length of each microtunnel is approximately 1.4 km (approximately 1 km is below the land surface and approximately 0.4 km of the microtunnel is below the seabed). The microtunnel will enable the crossing of the Varvarovka to Sukko road and the Shingar River without any damage or interruption.

Each microtunnel will be a circular shape and will have an outer diameter of approximately 2.5 m.

The location of the four microtunnels is shown in Figure 5.20 and a longitudinal profile of the microtunnel for pipeline #1 is illustrated as an example in Figure 5.21. All four pipelines will have similar longitudinal profiles. The construction of the microtunnels will consist of the following main activities:
• Excavation and construction of the entry shaft to launch the TBM followed by the concrete jacking pipes;

• Excavation of the microtunnel, which will be continuously lined by the concrete jacking pipes;

• Excavation of the offshore microtunnel exit pit and recovery of the TBM; and

• Pipeline installation and grouting of the microtunnels.

An illustration of a typical microtunnel being constructed is shown in Figure 5.22 and a list of the equipment necessary to construct the microtunnels is provided in Table 5.9. The construction of the microtunnel will require construction activities to be undertaken in both the landfall and nearshore sections of the Project Area. This section of the chapter provides details on the activities associated with the landfall section although makes reference to activities in the nearshore section in order to clearly set out the microtunnelling construction process. More detailed information on the construction activities within the nearshore section is provided in Section 5.3.4.
NOTES

1. Elevations are in meters, relative to Baltic System of Heights (BS).
2. Minimum cover 1.22 m. from top of precast concrete slab.
3. Length and extend of precast concrete slabs to be determined during detail design.
4. Cover depth of pipeline section in crossing and location of concrete protection slab to be re-evaluated with additional survey data, to be available for detail design.

Entry Shaft Construction

A microtunnel entry shaft is required to ensure that the TBM commences excavation of the microtunnel at the correct angle. It is estimated that the entry shafts will be approximately 10 - 12 m deep and 12 m in diameter. The entry shafts are formed by drilling piles (typically a combination of reinforced and unreinforced bored concrete piles) to the required depth around the shaft location to form a continuous circular secant piled wall (secant pile walls are formed by constructing intersecting reinforced concrete piles) for the shaft. Once the outer frame is in place, the shaft will be excavated out to the required depth and a reinforced concrete slab will be constructed at the base of the shaft. Each shaft will require approximately 1,250 m$^3$ of material to be excavated and approximately 600 m$^3$ of concrete to form the shaft walls.

*Complete.*
**Microtunnel Excavation**

Microtunnelling will be undertaken using a remotely controlled TBM, which is lowered into the entry shaft by a crane. The microtunnelling operation will be undertaken on a 24 hour day, seven day per week basis and the average rate of tunnel excavation will be approximately 10 to 15 m per day. It is anticipated that each microtunnel will take approximately four months to excavate. The construction schedule assumes that each of the four microtunnels will be constructed one after the other; however, it is possible that the contractor (with agreement from South Stream Transport) could choose to construct two tunnels simultaneously.

In addition to the TBM, additional equipment will be used to advance and control the TBM and concrete jacking pipes and manage excavated soils and slurry. Further details on equipment are provided in Table 5.9.

The pipe jacking process which will be used to advance the TBM and concrete jacking pipes is shown in Figure 5.23. Approximately 485 concrete jacking pipes (each approximately 3 m long and 2.5 m in diameter) will be required for each microtunnel. Each jacking pipe section will have a spigot at one end and a socket at the other end. The spigot end of one pipe section is inserted into the socket of another pipe section with a secure seal being made between the two within the socket. It is anticipated that concrete jacking pipes will be delivered to the site pre-fabricated and ready for installation. Alternatively, they could be prepared at site within a temporary shed constructed within the Pipeline String Preparation Area (Site B).

**Figure 5.23 Pipe Jacking Process**

In addition to the main hydraulic pipe jack in the entry shaft, there will be a number of intermediate jacking stations installed approximately every 100 m along the microtunnel. The intermediate jacking stations effectively break the whole microtunnel jacking length into smaller pipe jacking sections and redistribute the total required jacking force.
The TBM will be equipped with an air lock. The air lock is effectively a decompression chamber that is attached to the TBM that allows workers to safely adjust to the atmospheric conditions at the tunnel face under compressed air.

TBMs have a rotating cutting head to excavate the ground material. The cutting head is lubricated with slurry made of water and bentonite (a natural, inert, non-toxic clay) that is pumped through hoses to the cutting head from slurry mixing equipment located in the microtunnelling construction site. The bentonite will be in a dry powder clay form and will be mixed with the fresh water in the microtunnel construction site prior to being pumped to the cutting head. It is estimated that approximately 1,200 tonnes of bentonite will be required for the slurry and lubrication to construct all four microtunnels.

Each microtunnel will require approximately 9,250 m$^3$ of freshwater during construction for lubrication, slurry production and grouting purposes. It is anticipated that the water will be supplied by tankers, which will collect the water from a well located at the northern edge of the village of Sukko as described in Section 5.3.3.2 and shown in Figure 5.8. It is estimated that a maximum quantity 10,000 m$^3$ of water may need to be stored for the construction of the microtunnel due to a five month restriction period (May to September inclusive) when water may not be taken from this source. The water required for slurry (5,000 m$^3$ per microtunnel) will be mixed with soda ash (known chemically as sodium carbonate (Na$_2$CO$_3$)) to achieve an ideal pH of approximately 9.0 before mixing with the bentonite in a standard mixing agitator. It is anticipated that approximately 25 tonnes of soda ash will be required for the construction of the four microtunnels. The additives in the slurry (e.g. bentonite) will be selected from the OSPAR/PLONOR list of substances. The Oslo Paris Commission (OSPAR)$^3$ List of Substances and Preparations Used and Discharged Offshore which are considered to Pose Little or No Risk to the Environment (PLONOR) contains a list of substances whose use and discharge offshore are subject to expert judgment by the competent national authorities or do not need to be strongly regulated.

A residual coating of the slurry mixture on the exterior of the concrete jacking pipes will help reduce the friction between the jacking pipes and the surrounding soil. The TBM is also equipped with a crushing cone to crush larger particles into smaller sizes for transport through the slurry lines, a hydraulic or electric motor to turn the cutting head, a pressurised slurry mixing chamber behind the cutter head to maintain face stability, an articulated steering unit with steering jacks for steering corrections, various control valves, pressure gauges, flow meters, and a data acquisition system. Additionally, the TBM has inline cameras to relay information to the operator and a target system for guidance control.

**Slurry and Waste Management**

Each microtunnel will require approximately 7,000 m$^3$ of material to be excavated. The drill cuttings are removed from the tunnel by means of slurry. Slurry pumps in the tunnel section behind the TBM will transport the slurry through pipes to the microtunnel construction site.

---

$^3$ OSPAR refers to the Oslo and Paris Conventions for the Protection of the marine Environment of the North-East Atlantic (OSPAR Conventions), 1992.
Most of the slurry (consisting of water, bentonite and drill cuttings) will be returned to the surface where a separation plant located within the microtunnel construction site will filter the slurry to remove the drill cuttings and store it in temporary mud storage tanks for re-use.

The separation plant contains various stages of modular units which incorporate physical grating shaker screen filters and hydrocyclone units. Each of the stages shown in Figure 5.24 will separate and remove materials of different sizes from the slurry starting with coarse rock particles from approximately 60 mm down to fine material of size just below 0.1 mm.

The soil separation process is shown in Figure 5.24 which illustrates that after the solids and fines separation, the slurry is returned via the pumped process and will re-circulate to the TBM face via the tunnel piped circuit, thereby completing the cycle. The slurry’s soil-carrying attributes will deplete over time in this process, due mainly to the inclusion of very fine excavated materials. The condition and capability of the slurry is constantly monitored. Either make-up slurry, which is mixed adjacent to the separation plant, or recycled/cleaned slurry, is added via the reservoir feed header tanks and replenishes the slurry circuit as needed.

All of the solid outputs of the slurry separation process will be removed from the temporary storage areas by dump truck to facilities capable of reusing the material (rock, gravel and sand), or to approved waste sites in accordance with national waste regulations if there are no means of recycling the material offsite or if the soil is contaminated.

The separation plant storage area shown in Figure 5.24 will be equipped with its own floor drainage system. Wet slurry draining from the separated material will run-off to local drains within the microtunnel construction site and from there it will be pumped into the recycled slurry process for reuse.

The unused waste slurry liquid that is residual from the centrifuge or filter press is recycled and re-introduced back into slurry preparation. After completion of the microtunnel works, any remaining slurry will be transported from the used slurry storage tank to a licensed waste facility, where it is typically handled as normal soil waste. By undertaking careful calculations of slurry requirements and using efficient slurry recycling systems, the amount of surplus slurry will be kept to a minimum.

**Excavation of the Offshore Microtunnel Exit Pits and Recovery of the TBM**

The recovery of the TBM at the exit of the microtunnel requires the excavation of an offshore exit pit for each pipeline. The exit pits are located approximately 400 m offshore in a water depth of approximately 23 m. Further information on the excavation of the microtunnel exit pits and TBM recovery is presented in Section 5.3.5.4.

Installation of the Pipeline in the Microtunnel

Following completion of each excavated microtunnel exit pit and trench in the nearshore section, the pipeline will be installed within the microtunnels using a pull-in winch. Welding, field joint coating and inspection of the pipeline string will be undertaken onboard a pipe-lay vessel located near the microtunnel exit pits. As the pipeline string is welded together onboard the pipe-lay vessel the completed pipeline is pulled through the transition trench and microtunnel from the stern of the pipe-lay vessel by a cable or rods connected to a linear winch located onshore within the microtunnel construction site.

The pipeline pull-in process will require some reconfiguration of the microtunnel construction site. This is to provide room for the pull-in equipment, including a suitable area for the installation of anchor hard points for the winch system and locating the winch and reel winder that will store the pull-in cable. The winch system will likely be constructed using sheet or tubular piles as anchors. It is anticipated that a multiple winch system will be required to provide the necessary force to pull-in each pipeline. The pipeline string will have the outer surface of the pipe coated with a Glass-Fibre Reinforced Plastic (GFRP) sheath to protect the 3LPP coating against impact or friction wear as it is pulled through the microtunnel. It is anticipated it will take approximately five days to complete the pipeline installation within each of the microtunnels.

Construction activities in the nearshore section associated with the installation of the pipeline in the microtunnels is described in more detail in Section 5.3.5.5.

Following pipeline installation within the microtunnel, a tie-in between the microtunnel pipeline string and the open-cut landfall section pipelines will be made within the entry shaft.

Grouting of Microtunnels

The gap between the outside of the pipeline and the inside wall of the microtunnel will be filled with grout following hydrotesting of the landfall and nearshore sections of the Project pipelines (described in more detail in Section 5.4.2). The purpose of the grout is to secure the pipelines within the tunnels. The grout (a mixture of cement, bentonite and freshwater) will be batched within the microtunnel construction site. Approximately 5,500 m³ of grout will be required per tunnel, and 22,000 m³ for all four tunnels.

Prior to grouting, both ends of the microtunnels will be sealed. At the entry shaft end, a brick wall is built by hand and sealed around the product pipeline and the various grouting fill pipes. The grout shall be pumped into the flooded and sealed microtunnel from the entry shaft end through several injection tubes until the microtunnel is completely filled. This process will displace the seawater through a seaward-end outlet pipe. It is expected that a certain amount of mixing of the grout with the seawater will occur. The expelled water will be monitored at a sea surface outlet pipe where it is expected a mixture including some grout will eventually appear. The amount of mixed material that may be released to the marine environment is estimated to be small.

The mixed material will be tested and if it is deemed to contain too much solid grout material for discharge to sea (as determined by local regulations and international standards), it will be
pumped to a tank upon a vessel at the microtunnel exit pit where separation of the grout from the seawater will be undertaken using on-board filtering equipment. There are three possible filtering methods that could be selected:

- Settlement and dilution with seawater;
- Centrifuges; and
- Flocculation.

The chosen filtering option will be selected by the installation contractor based on the quantity of mixed material, the grade of grout, and water pH and temperature. The grouting process will be monitored until the correct (input) concentration of grout appears on the discharge end. The grouting pipes at both ends of the microtunnel will be plugged and the microtunnel construction will be completed.

### 5.3.4.5 Landfall Section Construction Material Use, Utilities, Waste and Emissions

#### Material Use

During construction of the landfall section pipelines and landfall facilities a number of materials will be required. An estimate of the quantities of the main materials to be consumed for construction of the four landfall section pipelines and landfall facilities are shown in Table 5.10. Quantities shown are approximate and subject to final optimisation during the detailed design process.

<table>
<thead>
<tr>

</table>

*Continued...*
Material | Quantity (all four pipelines)
---|---
**Landfall Facilities**
Steel (piping and equipment) | 6,000 tonnes
Concrete (foundations of piping, equipment and containers) | 10,000 tonnes
Imported fill material for site preparation (stone/rock) | 134,000 tonnes
Field Joint Coating (HSS) | 80 sleeves
Weld Material | 0.5 tonnes
Paving Blocks / Slabs (to form areas of hardstanding) | 6,000 tonnes
Crushed Rock (paving foundations) | 8,000 tonnes
Gravel (surfacing of areas outwith hardstanding) | 6,000 tonnes
**Access Roads and Temporary Facilities**
Rock for access roads | 297,331 m³
Asphalt concrete for access roads | 960 m³
Rock for temporary facilities hardstanding areas | 62,930 m³
*Complete.*

**Fuel Use**

It is anticipated that an average of approximately 4.1 m³ of diesel per day will be consumed by construction vehicles and equipment required for the construction of the landfall section. Diesel required for construction will be delivered to the construction sites by appropriately licenced road fuel tankers.

**Fuel / Chemical Storage and Refuelling**

There will be dedicated plant and vehicle refuelling areas within the construction sites, which will be situated away from surface waters, groundwater and surface water drains. Fuel tanks will be bunded. Secondary containment will be provided by forming an impermeable bund (i.e. a wall) around the refuelling area to provide containment in the event of a spill or rupture. Both storage tank and secondary bunding will be sufficient to contain at least 110% of the volume of fuel being stored. The location of the fuel tank storage areas within the construction sites will be subject to contractor preference.

Strict procedures will be followed when refuelling to minimise the risk of spills to the environment. All refuelling activities will be undertaken in line with requirements set out in the
Russian Landfall CMP, which will be developed as part of South Stream Transport’s ESMP. The requirements of the CMP need to be met by both South Stream Transport and the appointed contractors (and sub-contractors). Other fuels, oils and chemicals will be securely stored in clearly marked containers in a contained area to prevent pollution. It will also be ensured that spill kits, containing clean-up/absorbent materials etc. are stored in close proximity to the refuelling areas and with any mobile fuel bowsers.

Chemicals and materials will be clearly labelled and Material Safety Data Sheets (MSDS) will be displayed at point of storage. Chemical and material storage areas will be well maintained, neat and tidy, with adequate inventory control. Chemical storage will be weather-proofed and on bunded hard standing. The bunds and hardstanding will be impermeable and resistant to the materials being stored. Requirements for the chemical storage will be set out in the Russian Landfall CMP.

Water Consumption

During construction of the landfall section water will be required for domestic purposes (drinking water, mess and welfare facilities) and industrial use (for example wheel washing, dust suppression; and microtunnel construction). Water will be brought in by road tankers. Bottled water will be provided for drinking purposes. The estimated consumption of water is presented in Table 5.11. Water requirements for hydrotesting are described in Section 5.4.

Table 5.11 Estimated Water Consumption during Construction of the Landfall Section

<table>

<td>37,000 m³</td>
</tr>
<tr>
<td>Freshwater</td>
<td>Various use (dust suppression, wheel washing etc.)</td>
<td>5 m³ per day</td>
</tr>
</tbody>
</table>

Utilities

Utilities required during the construction of the landfall section will include:

- **Power** – the power required by plant, machinery and temporary offices etc. within the construction sites and construction corridor will be provided by diesel generators. When required, the generators will be refuelled by mobile bowsers;

- **Water** – potable and non-potable water will be available within the temporary construction sites shown in Figure 5.10. Water for general use within construction sites and construction corridor (including wheel-washing of vehicles going off-site, and dust suppression methods if necessary) will be supplied by bowsers as required. As described in Section 5.3.3.2, water will be sourced from a well near Sukko. Due to seasonal restrictions (May to September inclusive) when water may not be taken from this source it is anticipated that the
Contractor may require to store up to 10,000 m³ of water in large water tanks within the Pipeline String Preparation Area (Site B) for microtunnel construction and up to 800 m³ of water at the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E) for general construction use and hydrotesting of the landfall facilities pipework. The exact storage locations and dimensions of the storage tanks will be finalised during the detailed design and will be agreed between the Contractor, South Stream Transport and the relevant Local Authorities;

- **Sewage** – temporary sanitary facilities (i.e. chemical toilets) will be provided at a number of locations across the construction sites. Sewage will be contained and tankered and then collected by an appropriately licenced waste haulier to take the sewage offsite for appropriate treatment; and

- **Drainage** – to prevent possible pollution of surface waters, sediment and erosion controls, including appropriate drainage systems, will be implemented at construction sites to manage run-off and to limit the loss of soil from the site. The drainage systems will separate out the sediments from the drainage water and will include oil interceptors. Where vehicles carrying concrete and other equipment are required to be washed out on site this will be undertaken in dedicated bunded areas.

### 5.3.4.6 Summary of Waste Generated during Construction of Landfall Section

There are a number of activities during the Construction Phase of the landfall section that have the potential to generate waste. Table 5.12 presents a summary of the waste types anticipated to be generated using the Federal Waste Classification Catalogue (FWCC), in accordance with Ministerial Order 786 “On the adoption of the Federal Classificatory Catalogue of Wastes” (Ref. 5.7) to categorise waste types.

All wastes will be collected, stored and transported off-site in appropriate bins and containers in accordance with applicable Russian Federation waste policy. The locations of potential waste disposal facilities which may be used for the Project are shown in Figure 5.9 However, it should be noted that no decisions as to which of these sites could or may be used have been taken at this time and will be subject to further investigation. Only appropriately licenced companies will be employed for the transportation, recycling and disposal of waste. Further information on waste generation and management, including predicted quantities, is described in **Chapter 18 Waste Management**.

5.3.4.7 Emissions to Atmosphere during Construction of the Landfall Section

Table 5.14 presents the anticipated GHG and non-GHG emissions from the construction and installation (excluding pre-commissioning (Section 5.4)) of the landfall section pipelines and landfall facilities based on the expected plant and equipment required on site outlined in Table 5.7 and Table 5.9.

Further information on emissions to atmosphere is provided in Chapter 9 Air Quality.

5.3.5 Construction of Nearshore Section

5.3.5.1 General Overview

The nearshore section of the Project Area commences at the exit of the microtunnels in a water depth of approximately 23 m and extends out to a water depth of approximately 30 m where an above water tie-in between the nearshore and offshore section pipelines will be made.

The main construction activities in the nearshore section include:
- Surveys of the pipeline route prior to, during and after the pipe-laying process;
Chapter 5 Project Description

- Dredging of each microtunnel exit pit and transition trench and recovery of the TBM on four occasions;
- Installation of the pipelines in the microtunnels;
- Pipe-laying;
- Backfilling of the microtunnel exit pits and transition trench; and
- Tie-in of the nearshore / offshore pipeline sections at the 30 m water depth.

Furthermore, there will be a requirement to temporarily store some of the dredged material from the microtunnel exit pits and transition trenches for the duration of the dredging works associated with each respective pipeline. The stored material will be used for backfilling of the exit pits and trenches following pipeline installation. Temporary storage areas will be located adjacent to the microtunnel exit pits, to the north, as indicated in Figure 5.20.

Marine plant and equipment used for the Project that originates from outside the Black Sea brings a risk of introducing marine invasive alien species. Specific measures will be adopted to reduce this risk. Where relevant and practical, these measures will be based on those identified in the IPIECA (Global Oil and Gas Industry Association for Environmental and Social Issues) document *Alien Invasive Species and the Oil and Gas Industry, Guidance for Prevention and Management* (Ref. 5.8) and the International Maritime Organization (IMO) *Ballast Water Management Convention and Guidelines* (Ref. 5.9). They will be applied to all marine plant and equipment that is used on the Project and which has the potential to be a vector of live organisms, spores, larvae and young and will include ballast water management, use of antifouling coatings, cleaning of equipment prior to deployment and the change of cooling water. Ballast management will be included in the Vessels and Marine Transport CMP. Further information on the Vessels and Marine Transport CMP and South Stream Transport’s ESMP are described in Chapter 22 Environmental and Social Management.

### 5.3.5.2 Nearshore Vessel Spread

Table 5.16 presents a summary of the type and number of vessels that are anticipated to be used during the nearshore pipeline installation works.

Construction activities associated with the installation of the nearshore pipelines will require a number of vessels. The main vessel will be the vessel required for the installation of the pipeline in the microtunnels, which may be a multipurpose vessel equipped with winching gear or a shallow water pipe-lay vessel depending on the installation method selected by the contractor. In addition, other vessels will be involved in construction activities, such as dredging vessels, support vessels (survey, dive support, etc.) and supply vessels (pipes, fuel and provisions). The vessels associated with the marine pre-commissioning spread are presented in Table 5.31.

The actual vessel spread will depend on the contractors preferred method of pipeline installation in the microtunnels and the availability of vessels at the time that the necessary construction permits are granted.

5.3.5.3 Surveying

The design and routing of the microtunnels and nearshore section of the pipelines has been informed by a number of studies as outlined in the baseline data sections of Chapters 7-18 of this ESIA Report. However, a number of further surveys will be required before, during and after installation of the pipeline.

Pre-Construction Surveys

Pre-construction surveys will be carried out along each pipeline route prior to commencement of the dredging and pipe-lay works. The purpose of such surveys is to confirm the previous route surveys and optimise the exact route of the pipeline. The survey will typically include a range of standard geophysical survey techniques, and/or visual surveys using a remotely operated vehicle (ROV).

These surveys will also confirm the need for and guidance of the removal of boulders, rocks or potentially unexploded ordnance (UXO). Potential UXO could constitute a danger for the construction workers, the pipelines and the environment during the installation works and the operational life of the Project.

UXO surveys will be carried out in specific areas along the pipeline route where there is a higher likelihood of UXOs being present in advance of the pre-lay surveys. Identified UXOs will either be avoided through re-routing or cleared. A UXO Clearance Plan will be developed by the Contractor in close conjunction with South Stream Transport and relevant national authorities. However, a final check for the presence of UXOs may be undertaken during pre-lay surveys ahead of the pipe-lay spread.

It is anticipated that some of the vessels working in the nearshore section will use anchors. Therefore, an anchor corridor survey will also be carried out within a corridor on either side of the pipeline routes, the area of which will be calculated by the EPC contractor. Within this corridor, anchors from dredgers, pipe-lay vessel or anchor handling tugs may be laid on the seabed during installation of the pipelines.

The primary purpose of the anchor handling survey is to identify potential risks that will result from anchoring activity, as a result of the presence of potential UXO, anthropogenic debris or geological features and also Cultural Heritage Objects (CHO), which require safeguarding from damage by the anchors, and to avoid or minimise disturbance of sensitive habitats. The surveys will include standard geophysical and visual survey (such as ROV) techniques and the results will be subject to expert evaluation. Where UXO, CHO, sensitive habitats or potentially dangerous debris is detected, anchor exclusion zones will be established where practicable. The appointed pipeline installation contractor will be required to develop anchor patterns and procedures and undertake a risk assessment to ensure that the areas of concern are not impacted by the anchors or the sweep of the anchor cables.

Touch-down Monitoring and As-Laid Surveys

During installation of the pipelines in the nearshore, real-time touch-down monitoring will be conducted to ensure correct installation of the pipeline with regard to its alignment and with
respect to lateral separation between adjacent pipelines. The real-time monitoring will ensure that boulders and, potential UXOs are avoided and that environmentally and culturally sensitive areas are not accidentally encroached by the pipelines. An as-laid survey will be performed once each pipeline has been laid on the seabed. The survey will establish the as-laid position (horizontal and vertical) and condition of the pipeline and would comprise bathymetry and other survey sensors in conjunction with visual inspection by ROV.

**As-Built Survey**

After completion of pipe-laying works, an as-built survey will be conducted to ensure the pipeline has been installed correctly, to document the condition and to ensure the integrity of the installed pipelines. The survey will comprise the integration of as-laid survey results from free-lay installation operations with the post-installation rectification/acceptance surveys for specific construction activities, e.g. crossing supports, post-lay interventions and site rectification.

### 5.3.5.4 Excavation of the Offshore Microtunnel Exit Pits and Recovery of the TBM

The recovery of the TBM at the exit of each microtunnel requires the excavation of an offshore exit pit. The exit pits are located approximately 400 m offshore. At the microtunnels exit locations, the spacing between the centreline of the pipelines will be approximately 50 m, and consequently each microtunnel will require its own exit pit. The microtunnel exit pits will be located in a water depth of approximately 23 m and the topside of the microtunnel will be approximately 3 m below the surface of the seabed.

From the microtunnel exit pit, the pipelines will be laid in a pre-dredged transition trench for a length of approximately 170 m out to a water depth of approximately 26 m. The exit pit and trench will be excavated in a single dredging operation. The transition trench will gradually reduce in depth as it moves away from each microtunnel exit pit (located approximately 5 m below the seabed surface) to provide a shallow gradient transition for the pipeline between each microtunnel exit pit and the seabed surface itself as illustrated in Figure 5.25.

The TBM will be recovered from each exit pit using a barge that will be fitted with a crane to lift the TBM from the water. The TBM will be transferred back to the microtunnel construction site where, following any necessary repairs, it will start work on the next microtunnel, or alternatively, it will be demobilised on completion of all four microtunnels.

When the TBM emerges into each exit pit, there will be a small discharge of slurry into the marine environment. However, this will be carefully controlled by reducing the pressure of slurry supplied to the TBM on nearing emergence to each exit pit and immediate shutdown of the TBM slurry circuit when the TBM emerges into each exit pit. Since bentonite is denser than seawater, the slurry tends to stay on the seabed rather than mix with the surrounding water column. Furthermore, the depth of each exit pit (approximately 5 m) will reduce the exposure of the slurry to seabed currents and will capture the majority of slurry discharged from the tunnel. The slurry mixture can then be collected and disposed of onshore.
It is anticipated that a Cutter Suction Dredger (CSD) or a grab crane will be employed to dredge each microtunnel exit pit and associated transition trench. A trailing suction hopper dredger (TSHD) may be employed, if sediment conditions allow (the TSHD cannot be used for hard sediments/rock), to dredge part of the trench, and to clean out the trench prior to pipeline installation if it has backfilled with sediments.

A CSD is either anchored to the seabed or kept in position by poles (known as spuds) that penetrate into the seabed below the barge. A CSD is equipped with a rotating cutter head, which cuts hard soil into fragments. The cut soil is sucked in by dredge pumps and then transported away from the trenches to a specified location using pumps and a floating pipeline attached to a spreader pontoon. Alternatively, the spoil can be loaded into a split hopper barge moored alongside, which in turn can then transport the dredged spoil to the specified storage area. A schematic of a typical CSD vessel is shown in Figure 5.26.

**Figure 5.26 Schematic of a Cutter Suction Dredger**

Floating grab cranes are mounted on a pontoon (either self-propelled or stationary) and dredge material using a bucket mounted to the crane, the jaws of which are opened and closed like a clamshell to trap sediments. The grab cranes deposit excavated material in independently operated split hopper barges, which transport the dredged material to the desired location. The pontoon is usually anchored by spuds, however in exposed locations or in deeper waters anchors can be used to increase stability.
The TSHD uses a drag head attached to a suction pipe to excavate material from the seabed. The excavated material is then stored in compartments (hoppers) on the vessel itself. The excavated spoil is temporarily stored offshore until it is re-utilised to bury the pipelines. A schematic of a typical TSHD vessel is shown in Figure 5.27.

**Figure 5.27 Schematic of Trailer Suction Hopper Dredger**

Each pipeline will be laid in an individual trench from the microtunnel exit point to a water depth of approximately 26 m depth. Each trench will be approximately 170 m long with side slopes of approximately 1:4 and width of approximately 10 m at the trench bottom. The trench will be excavated to a maximum depth of approximately 5 m at the microtunnel exit point with the excavation depth gradually reducing to the 26 m water depth where the pipeline will start to be laid directly onto the seabed. This will result in an estimated dredged volume of 25,000 m$^3$ per pipeline.

The total estimated volume of material to be dredged for all four pipelines (for the four microtunnel pits and four transition trenches) is approximately 100,000 m$^3$. A summary of the dredging required is shown in Table 5.17.

**Table 5.17 Estimated Volume of Dredged Material in the Nearshore Section**

<td>1:4</td>
<td>10</td>
<td>Gradually decreases from 5 m to 0 m</td>
<td>25,000</td>
<td>100,000</td>
</tr>
</tbody>
</table>
Material removed from the dredged trenches may be deposited either adjacent to the exit pits and trenches or in a temporary storage area located to the north of the microtunnel exit pits and transition trenches as shown in Figure 5.20. The dredged materials may not be able to be stored immediately adjacent to the trenches as there is the potential for sea currents to transport the sediments and refill the trenches prior to pipe installation. Following pipe installation in the trenches, the stored material will be dredged back up (using the same dredging equipment used previously) and used to backfill the microtunnel exit pits and transition trenches. Backfilling of the trenches with the direct placement of the previously excavated sediment over the pipelines will not be undertaken until completion of pre-commissioning tests. It is anticipated the material from each exit pit and trench will be stored for approximately two months, before it is dredged back up and used as backfill.

A detailed Dredging Management Plan will be developed once the dredging contractor has been appointed and the dredging plant identified. This will be developed by the Contractor in collaboration with South Stream Transport and the regulatory authority.

5.3.5.5 Installation of the Pipelines in the Microtunnel and Nearshore Section

Installation of Pipelines within the Microtunnels

As described in Section 5.3.4.5, following completion of the microtunnels, the pipelines will be installed within the microtunnels by welding together the pipeline string on an anchored pipe-lay vessel located near the microtunnel exit pits. The pipeline string is pulled through the transition trench and microtunnel towards the onshore entry shafts with a cable or rod system connected to a winch located within the onshore microtunnel construction site.

Upon completion of the microtunnel pipeline installation, pipe-lay in the nearshore section will be continued by the pipe-lay vessel laying away from the Russian coast towards the tie-in location at 30 m water depth. The construction activities associated with pipe-lay in the nearshore section is described in the following section.

Pipe-lay in the Nearshore Section

Pipe-lay in the nearshore section is accomplished by the sequential alignment, welding and lowering of pipe from a shallow water pipe-laying vessel. Pipe sections are transported to the pipe-lay vessel pre-coated with polypropylene anti-corrosion coating and internally with epoxy flow coating. Furthermore, to ensure the protection of the pipelines in shallow water, concrete coating of the pipelines is undertaken to provide on-bottom pipeline stability and also acts as a safety measure to avoid damage through interaction with respect to third party activities (for example, trawling gear and anchors). The concrete coating protecting the pipelines will be approximately 50 mm thick. It is anticipated that pipelines will be concrete coated out to a water depth of approximately 88 m.

The pipes are carefully stacked on board the pipe-lay vessel using deck cranes. The pipes are then transported using conveyor systems to the pipe bevelling station where the pipes are made ready for welding. Bevelling consists of shaping the edge of the pipe, which is to be welded, so that the weld itself fits within the overall pipe profile. The bevelling process produces
large volumes of scrap metal which require to be stored in containers for collection and disposal onshore. It is estimated that approximately 161 tonnes of bevel waste will be generated by the construction of each pipeline from each microtunnel exit pit to the Russian and Turkish EEZ boundary.

Following bevelling, the pipes are transported to the line-up station, where the pipes are lined up in preparation for welding, using traverse carriage (roller) systems. This is the beginning of what is called the firing line.

Following alignment, the pipe sections are moved along the firing line to the first welding station where the pipe sections are clamped and joined together using automatic welding techniques. Root pass (first, and most critical layer of a multi-layer weld) and hot pass (second weld, which cleans out any remaining slag from root pass) welds are undertaken in the first welding station before the pipe is then moved to subsequent weld stations for the external welds to be completed. When the welding process is completed, the welded pipe section is moved to the inspection station where the weld is subject to visual inspection and NDE to ensure the weld meets the required specification. Any welds not meeting the required specification will be cut and the pipeline re-welded and subject to full NDE.

Following successful weld testing, the pipes move along to the coating stations. The number of coating stations will depend on the pipe-lay vessel used. In the coating stations, field joint coating will be applied to the welds for corrosion protection. For concrete coated pipe sections, infilling of the gap between the concrete ends of the pipe sections will be undertaken with moulded solid polyurethane or polypropylene to ensure a flush outer pipe surface is obtained.

All critical processes onboard the pipe-lay vessel will be inspected by the pipe-lay contractor's quality assurance crew, and thereafter inspected by representatives of the certification company and South Stream Transport.

The newly welded, coated and inspected pipe section is then moved into the water via the stinger, which is buoyancy controlled to maintain a smooth curve profile to the target water depth to minimise stresses on the pipeline during installation. Stingers are a steel structure, which extend from the stern of the vessel to support the pipe as it is moved into the water, as well as control the curvature of the installation.

During the installation of the pipeline in the microtunnel, the pipeline string will be pulled from the pipe-lay vessel by the land based winch. However, during pipe-lay in the remainder of the nearshore section the pipe-lay vessel moves the pipe section into the water by advancing an appropriate distance (dependent on pipeline string length) by pulling on its anchor lines, resulting in the pipeline string exiting the pipe-lay vessel via the stinger. Once the pipeline string has exited the pipe-lay vessel, the pipe-lay vessel will stop forward motion, and work on welding the next pipeline string together commences.

Pipe-lay in the nearshore section will be performed by the S-lay technique. The S-Lay technique requires the load out of single 12 m pipe sections to the pipe-lay vessel. This method involves welding the pipe sections horizontally, and continuously ‘feeding’ the jointed sections over the vessel’s pipe-lay stinger from the stern of the vessel as the vessel moves forward in such a way that the pipeline forms an “S” shape from the vessel’s exit point to the touchdown point on the seafloor. Sufficient tension is required during the S-Lay process to avoid overstressing the
pipeline. This is maintained via tensioning rollers and a controlled forward thrust, that keeps the pipe from buckling. Figure 5.28 presents a schematic drawing of the S-Lay pipe-lay method.

**Figure 5.28 Schematic of S-Lay Pipe-Lay Method**

It is anticipated that it will take approximately one day for the S-Lay pipe-lay vessel to complete pipe-lay in the nearshore section out to 30 m water depth following the installation of the pipeline in the microtunnel, depending on weather conditions.

In order to lay pipe in shallow water, a vessel must be of shallow draft. This shallow draft typically requires a flat bottom vessel with limited or no built-in propulsion systems. Figure 5.29 shows a typical shallow water S-Lay vessel.

Typical shallow water vessels are outfitted with anchor winches, anchor wires and anchors. Typically, an anchored vessel deploys 8 to 12 anchors in a semi-circular pattern in the fore and aft position, generally from its four corners. There are normally two or three anchor wires located at each corner of the vessel. During pipe-lay, an anchor handling tug boat is used to run the anchors out in a pattern that allows the pipe-lay vessel to move itself ahead by hauling in wire on the forward winches while paying out wire on the aft winches. As pipe-lay continues, the tug boat(s) continually re-locate the anchors forward as necessary to allow the vessel to lay pipe without delays. It is estimated that all anchors will be re-positioned for every 1 km of pipeline laid. The position of the anchors could be as far as 1.5 km (0.8 nautical miles (NM)) from the centreline of the vessel, depending on the water depth and pipe-lay vessel used. A typical pipe-lay vessel anchor pattern is shown in Figure 5.30.
Figure 5.29 Typical Shallow Water S-Lay Vessel

Image supplied courtesy of Allseas, Switzerland

Figure 5.30 Typical Pipe-Lay Vessel Anchor Spread
A safety exclusion zone will be enforced around the pipe-lay vessel during pipe-laying. A safety exclusion zone of approximately 3 km (1.6 NM) radius (depending on the extent of the anchor spread) around the pipe-lay vessel will be enforced during pipe-laying to avoid incidents with marine traffic. Agreement with the appropriate marine authorities shall be obtained regarding the exact exclusion distances and safety measures to be adopted during pipe-laying to avoid incidents with marine traffic. Unauthorised vessels including fishing vessels will not be permitted access to the safety exclusion zone. The pipe-lay vessel will be equipped with navigation lights, radar and radio communications. Due to the construction spread advancing along the pipeline route as the pipe is laid, constant (at least daily) consultation will be undertaken by the pipe-lay contractor with the appropriate marine authorities to inform them of the location of the construction spread. The marine authorities will then be responsible for informing marine traffic of the location of the pipe-laying activities and the associated exclusion zones. Further information on safety exclusion zones and marine navigation safety measures will be included in the Vessels and Marine Transport CMP which is outlined in Chapter 22 Environmental and Social Management.

Following completion of the nearshore pipe-laying at the 30 m water depth location, a temporary subsea laydown / test head (capable of launching and receiving PIGs) will be fitted to the end of each pipeline. The pipeline is then lowered to the seabed and left there until pre-commissioning tests of the landfall and nearshore section pipelines are carried out as described in Section 5.4.2.

After the successful pre-commissioning tests of the landfall and nearshore sections, the two ends of the pipeline (nearshore and offshore sections) will need to be joined (tied-in) above water. The above water tie-in will be performed where the water depth is approximately 30 m. The pipelines will be picked up from the seabed by the pipe-lay vessel by means of a davit wire connected by divers to the laydown head on the pipeline and subsequently winched on to the pipe-lay vessel.

The two pipeline ends are lifted above the water to the side of the pipe-lay vessel to enable a dry welded connection to be made. Following cutting of the two pipeline ends to the correct length, the ends are welded together. The weld will be subject to NDE prior to application of the field joint coating and careful lowering of the connected pipeline back to the seabed. This process will be carried out for each of the four pipelines.

A safety exclusion zone of approximately 0.5 km (0.3 NM) radius for tie-in construction vessels will be adopted during construction to avoid incident with marine traffic.

5.3.5.6 Reinstatement of Nearshore Section

Backfilling of the dredged microtunnel exit pits and transition trenches with spoil stored in the temporary storage locations will be undertaken following successful pre-commissioning tests of the nearshore and landfall section pipelines. It is anticipated that it will take approximately four days to backfill and reinstate each microtunnel exit pit and transition trench. Final seabed relief and bathymetry restoration of the microtunnel exit pits, transition trenches and temporary storage areas will be performed using side scan sonar and a survey vessel to perform bathymetric surveys. Both survey vessels and the dredgers used in the works will be equipped with a positioning system that allows them to work with the necessary precision.
5.3.6 Construction of Offshore Section

5.3.6.1 General Overview

The main activities in the offshore section of the Project Area include:

- Surveys of the pipeline route prior to, during and after the pipe-laying process;
- Offshore pipe-laying;
- Seabed intervention works;
- Crossings of existing offshore cables; and
- Tie-in of the nearshore / offshore sections.

5.3.6.2 Offshore Construction Vessel Spread

As with the nearshore section, the contracts for the installation of the Pipeline in the offshore section have not yet been awarded. However Table 5.18 presents a summary of the type and number of vessels that are anticipated to be used during the installation of a single offshore section pipeline. The actual pipe-laying spread will depend on the availability of vessels at the time that the necessary permits are granted.

The main vessel required will be the pipe-lay vessel. In addition, other vessels will be involved in the pipe-laying activities, such as support vessels (survey, dive support, crew change) and supply vessels (pipes, fuel and provisions).

5.3.6.3 Surveying

As described in Section 5.3.5.3, a number of further surveys will be required before, during and after installation of the pipeline. Please refer to that section for a description of these surveys.

5.3.6.4 Offshore Pipe-laying Process

Offshore pipe-laying is accomplished by the sequential alignment, welding and lowering of pipe from the pipe-lay vessel. Pipe sections are transported to the pipe-lay vessel pre-coated with polypropylene anti-corrosion coating and internally with epoxy flow coating. The pipe fabrication process on board the pipe-lay vessel (bevelling, line-up, welding and inspection etc.) will be similar to the process described for the shallow water S-Lay vessel in Section 5.3.5.5.

* This indicative number only accounts for the maximum number of PSVs that may be present within the 'Offshore (30 mbsl - 600 mbsl)' section of the Russian EEZ whilst pipe-laying is undertaken in that section. A PSV will also pass through this section to reach the construction spread when it is pipe-laying in the Nearshore Section in Russia. This additional movement is accounted for in the fuel use (Table 5.24) and emission estimates (Table 5.28).

† This indicative number only accounts for the maximum number of PSVs that may be present within the 'Offshore > 600 mbsl' section of the Russian EEZ whilst pipe-laying is undertaken in that section. PSVs will also pass through this section to reach the construction spread when pipe-laying to the east of the 600 mbsl location. These additional PSV movements are accounted for in the fuel use (Table 5.24) and emissions estimates (Table 5.28).
Offshore pipe-laying may be performed by the S-lay technique, or by a combination of S-lay and J-lay techniques. The method chosen mainly depends on water depth and/or cost/availability of an installation vessel. At the time of preparing this ESIA Report, the technique(s) to be employed for pipe-laying in the offshore section have yet to be confirmed. Therefore, it is assumed that either technique may be used for the Project and both are described in the following sections.

The S-Lay technique requires the load out of single 12 m pipe sections to the pipe-lay vessel, whilst the J-Lay technique requires some prior welding of the pipe sections at the marshalling yards in Bulgaria before load out to the offshore pipe-lay vessel. The average pipe-lay rate for S-Lay technique is expected to be in the order of 3.5 km per day (24 hour period), depending on weather conditions. Please refer to section 5.3.5.5 for further information on the S-Lay method.

For J-Lay, the pipe sections will be welded into strings of four pipes (quad joints), or two pipes (double joints). As described in Section 5.3.2.1, the welding, and field joint coating activities associated with quad jointing can be performed either onshore within a dedicated factory located in one of the marshalling yards in Bulgaria, or onboard a dedicated pipe-lay vessel that moors alongside the marshalling yard quayside and acts as the factory producing welded quads or double joints for load out to the J-Lay vessel offshore.

J-lay pipeline installation was developed for laying pipe in deep waters as it puts less stress on the pipeline by installing the pipeline from an almost vertical position. In the J-Lay method, the pipes are assembled and welded vertically in a tower erected on the centre or side of the pipe-lay vessel. A pipe tensioner or support frame is used to lower the pipeline string (quad or double joint) through the tower. As the pipe-lay vessel moves forward, the jointed pipeline is lowered near vertically in a J-shape from the launching point down to the bottom of the sea. The average pipe-lay rate using J-Lay technique is expected to be in the order of 2.75 km per day (24 hour period), depending on weather conditions. The J-lay method is considered to be suitable from a minimum water depth of 300 m, depending on the pipeline diameter. Figure 5.31 presents a schematic drawing of the J-Lay pipe-laying method.

The installation of the offshore pipeline section may require both intermediate depth and deep water pipe-lay vessels. An intermediate depth pipe-lay vessel is capable of working in a water depth range of approximately 20 m up to approximately 600 m. These vessels install the pipeline by the S-Lay method and may advance by pulling on their anchor lines or utilising dynamic positioning (DP) thrusters. DP is a computer-controlled system that drives the vessels thrusters (directional propellers) to maintain position without the use of anchors. A deep water pipe-lay vessel is capable of laying pipe in water depths from approximately 300 m to any depth required depending on the pipeline dimensions. These vessels are dynamically positioned and may use either the S-Lay or J-Lay methods.
Figure 5.32 shows a typical intermediate water depth S-Lay pipe-lay vessel and Figure 5.33 shows a typical deepwater J-Lay pipe-lay vessel.

For the majority of the offshore section pipe-lay work the pipe-lay vessel will be manoeuvred along the pipeline route using DP. Anchored vessels can potentially be used in water depths of up to 600 m, however for the Project it is anticipated that anchored pipe-lay vessels will only be used up to a maximum water depth of approximately 350 - 380 m. If anchors are used, up to 12 anchors may be deployed from the pipe-lay vessel and the position of the anchor itself could be as far as 1.5 km from the centreline of the pipe-lay vessel, depending on the water depth. As described in Section 5.3.5.3, an anchor corridor survey will be required. A typical anchor spread is illustrated in Figure 5.30.

A safety exclusion zone will be enforced around the pipe-lay vessel during pipe-laying of approximately 2 km (1.1 NM) radius for DP vessels and approximately 3 km (1.6 NM) radius for anchored vessels (depending on the anchor spread). As described in Section 5.3.5.5, agreement with the appropriate marine authorities shall be obtained regarding the exact exclusion distance to be adopted during pipe-laying to avoid incidents with marine traffic.

Figure 5.33 Typical Deep Water J-Lay Vessel

Image supplied courtesy of Saipem
If a combination of S-Lay and J-Lay methods are utilised it is anticipated that the S-Lay method will be employed from the 30 m water depth pipeline tie-in location out to a water depth of approximately 600 m, a distance of approximately 30 km, although the J-lay method could potentially be used from a water depth of approximately 350 - 380 m. At this location, an abandonment and recovery head is welded to the end of the pipeline to prevent sea water entering the pipeline and it is then lowered to the seabed by a davit wire connected to a winch on the S-Lay vessel and left on the seabed. The S-Lay vessel spread is then demobilised. The J-Lay vessel spread is then mobilised to the pipeline abandonment location. The pipeline is recovered by the J-Lay vessel using a recovery winch. The J-Lay vessel then commences pipe-laying towards the EEZ boundary of Russia and Turkey, a distance of approximately 195 km.

Although the EEZ boundary of Russia and Turkey is the downstream boundary of the Project, the J-Lay vessel will maintain pipe-laying through the EEZ of Turkey and Bulgaria to continue construction of the South Stream Offshore Pipeline.

**Pipeline Flood Protection during Installation**

A flood prevention device will be developed by the appointed pipe-lay contractor for installation within the pipeline during construction. The device will sit inside the pipeline close to where the pipeline touches down onto the seabed. As the pipe-lay progresses the device will be moved along the pipeline in the same direction as pipe-laying. The actual means of movement of the flood prevention device will be determined by the pipe-lay contractor during the development of the flood prevention device. However, possible methods are listed below:

- Air pressure from a start-up head;
- Control umbilical connected to the pipe-lay vessel; and
- A battery powered drive unit.

Each device will be designed to be controlled remotely and to allow adequate operation and monitoring control.

In the event that there is a loss of tension or loss of vessel position during pipe-laying causing the pipeline to become overstressed to the point where it ruptures and floods, then the flood prevention device will detect the change in pressure, will activate and seal the pipeline, thus preventing untreated sea water from flooding the pipeline. The damaged section of the pipeline between the flood prevention device and the pipe-lay vessel will then be removed and the undamaged pipeline section (protected by the flood prevention device) will be recovered back to the pipe-lay vessel and pipe-lay will resume.

**Pipeline Repair during Construction**

Emergency pipeline repair, including information on South Stream Transport’s Emergency Pipeline Repair Strategy (EPRS), during both the Construction and Pre-Commissioning Phase and Operational Phase is described in detail in Section 5.6.5.
5.3.6.5 **Seabed Intervention Requirements**

In the offshore section, the pipeline will be laid directly on the seabed. This technique will minimise seabed disturbance over most of the 225 km section. However, although the route of the pipelines has been designed to minimise seabed intervention requirements, some intervention will be required in specific areas, either before or after pipe-laying. This is to limit or remove pipeline free span lengths (for example in areas where the sea bed is rough and uneven), to protect the pipeline from geo-hazards such as rockfall in areas of excessive slopes (for example on the continental slope) and to protect the pipelines and cables at cable crossing locations.

The type and extent of seabed intervention which is currently considered to be necessary is described in the following sections and the locations are shown in Figure 5.34. Full intervention requirements will not be confirmed until detailed design studies have been completed; however, any changes are anticipated to be minor and are not anticipated to alter the results of this ESIA Report. Should any major design changes be required which may affect the results of the ESIA, the management of change process described in Section 5.11 will be followed. There are various intervention methods and within each method a wide range of alternatives exist, which may be applied depending on particular circumstances such as water depth, burial depth or soil conditions.

The seabed intervention methods can be divided in two main categories: pre-installation intervention and post-installation intervention.

Pre-installation methods include dredging, and placing of supports by means of gravel or mattresses in areas where free span pipeline sections are anticipated. For post-installation intervention, a wide variety of methods can be applied. Typical post-installation methods include post-lay trenching, rock dumping, placement of mattresses and the installation of Vortex Induced Vibration (VIV) suppression strakes. The various intervention methods that may be applied along the Project pipelines are described below.

The seabed intervention requirements are summarised in Table 5.19, Table 5.20 and Table 5.21. It should be noted that where supports are listed as being required, these may be installed either before or after pipe-laying. Similarly, there are locations where either pre- or post-installation trenching may be undertaken. The decision on the techniques to be employed will be subject to detailed design and preference of the appointed pipe-lay contractor.

Pre- and post-installation methods associated with cable crossings are described in Section 5.3.6.6.

Pre-Installation Seabed Intervention Requirements

As shown in Table 5.19, some pre-installation seabed intervention work is required in areas where sections of free span pipeline are anticipated due to the uneven seabed profile. Pre-installation seabed intervention methods proposed for the Project include dredging or mass flow excavation to remove shoulder spans, and the placement of pipeline support structures.

**Dredging**

Pre-installation dredging is undertaken to level or flatten out the seabed in areas of predicted pipeline spanning before the pipeline is laid. It is anticipated that approximately 42,500 m³ of seabed sediments will require to be dredged for all four pipelines to correct free span locations. The dredged sediments will be transported to an existing permitted underwater dump site for disposal (Disposal Site Number 923). The dump site is located on the Russian continental slope as illustrated in Figure 5.34. No other dredged sediment is proposed to be taken to this permanent disposal site.

Due to the water depths where pre-dredging is necessary (between approximately 110-150 m water depth) to remove shoulder spans it is unlikely that conventional dredging vessels such as CSDs or TSHDs will be employed due to restrictions in the water depths that they can operate in. There are however, grab crane dredgers (as described in Section 5.3.5.4) that may be able to operate at these depths. Alternatively, dredging at these depths could be undertaken using special ROV dredging tools / vehicles designed to work in deep water and on steep slopes, which are controlled by operators located aboard a support vessel.

One such tool is a grab excavation system that uses an ROV that is mounted on top of the grab for precise manoeuvrability of the grab. By using two lifting points – one forward and one aft - the excavation system is able to transport the excavated material underwater and deposit it where necessary. An alternative method is the use of a dredging vehicle that levels or flattens out the seabed using a combination of water jetting and suction to remove soil from the area.
The dredging head is installed on an extendable arm to cover the operational area. The dredging vehicle moves along the seabed using powered tracks and/or articulated walking legs and is capable of working on steep slopes. Both excavation tools are controlled from a support vessel.

*Mass Flow Excavation*

An alternative option is the use of a mass flow excavation tool. This tool is an ROV that uses subsea jetting equipment to excavate the seabed. The mass flow excavation tool generates a large volume column of water travelling vertically down to the seabed at high velocity. The water column hits the seabed at high speed to produce a powerful excavation force. This type of equipment allows for localised pre- and post-installation span correction in very deep waters in most soils without risk of damage to the pipeline. The excavation tool is controlled from a support vessel.

*Support Structures*

Support structures are strategically placed to provide vertical support to the pipeline at excessive span length locations. The exact details of the support structures are still subject to detailed design, although descriptions of typical methods are described below. Alternatively, it may be decided during detailed design studies to install these supports after pipe-lay or that the pre-installed supports for the VIV spans can be substituted with VIV suppression strakes. Suppression strakes are helical shaped plastic moulded structures which are designed to suppress damaging vibration forces to an acceptable level. If required, the strakes will be fitted to the pipelines on the pipe-lay vessel during pipe-laying.

Pre-installed supports may include concrete mattresses, structural support or rock berm, which need to be stable under earthquake and seabed currents conditions. Mattresses are normally installed from a vessel with a crane or A-frame with ROV support. Mattresses are available in different shapes and types and are generally made of concrete.

Rigid supports such as mud mats can also be installed to support the pipeline. Mud mats, which are made of steel (with self-sustaining cathodic protection system consisting of sacrificial anodes), consist of a base and top plate and a number of perpendicular vertical stiffeners that function as load-bearing beams. Rigid supports are installed with similar equipment as concrete mattresses, i.e. from a vessel with a crane or A-frame with ROV support. An indicative mud mat design is shown in Figure 5.35.
Alternatively, pre-installation rock dumping can be undertaken. Pre-installation rock dumping will involve the placement of rock berms, which are constructed using coarse gravel or small stones to locally reshape the seabed to provide support for the pipelines to ensure their long-term integrity. The rock berm length and spacing will vary with location and will not be confirmed until the detailed design stage. However, it is conservatively estimated at this time that each rock berm will have a footprint of approximately 100 m². The total volume of rock required to complete the works should rock berms be constructed at all pre-installation support locations is conservatively estimated to be approximately 8,600 m³.

Accurate placement of rock will be assured through the use of a dedicated rock-dumping vessel equipped with a fall-pipe, from which the rock is transported from the surface to just above the seafloor using suspended pipe sections. The shape of rock placements will depend on seabed conditions, but will be designed such that rock requirements are minimised. The end of the fall-pipe will be positioned by an ROV which is equipped with a positioning system to aid the accuracy of the rock placement and a post construction survey will be performed to confirm correct placement.

The placement of all rock material will be subject to a licence from the local authorities. The rock material selected will be chemically and mechanically stable for the entire lifetime of the Project. The type of rock selected will have to meet certain strength and durability requirements to ensure it lasts the length of the operational phase of the Project. The average size of the rock material will be 50 mm but may range from 20-100 mm. It will be a condition that the material used will not contain any contaminants, such as heavy metals.
Material for rock placement will be extracted from appropriately licensed onshore quarries or marine aggregate sites. At the time of preparing this ESIA Report, the source of rock material is unknown; rock may come from within Russia or from another country depending on the availability and quality of rock sources. Suitable rock types that could be used include basalt, gabbro and/or granite. The rock material will most likely be transported via a rock dump vessel and taken directly to the rock dump locations. Alternatively, if the rock comes from another country it may be transported by bulk carrier. If this is the case the rock will be transferred to a Russian port (Novorossiysk) and loaded onto a rock dump vessel.

**Post-Installation Seabed Intervention Requirements**

As shown in Table 5.19 some post-installation seabed intervention work is required in areas where sections of free span pipeline are anticipated due to the uneven seabed profile. Post-installation seabed intervention methods proposed for the Project include dredging (trenching) or mass flow excavation to remove shoulder spans and the placement of pipeline support structures. As shown in Table 5.20 post-lay trenching and backfilling of the trench with imported rock / stone may be required on the ridge of the continental slope (in water depths of between approximately 60 - 95 m) to provide the pipeline with additional stabilisation. The actual requirement for this intervention work will be confirmed during the detailed design stage as concrete coating of the pipeline alone may be sufficient to meet stabilisation requirements. As shown in Table 5.21 rock dumping is required over the pipelines in areas where they are at risk from rock fall on the continental slope.

**Mattresses and Grout Bags**

Concrete mattresses or grout bags may be required to rectify a single free span section on pipeline #1 if the as-laid free span length exceeds 110 m length and 1.7 m height. The requirement will be identified during post-lay surveys. If required, concrete mattresses or grout bags will be installed underneath the pipeline to provide vertical support. Concrete mattresses will be installed as per the description in the pre-installation section above.

Empty grout bags would be lowered to the seabed on a deployment frame from a vessel for ease of ROV manipulation and filling. The empty bag is placed under the pipeline and subsequently pumped full of grout material. The weight of the pipeline is taken by the grout bag as it fills. The grout then hardens to create a rigid support point.

**Post-Installation Dredging**

Post-installation dredging (also referred to as post-lay trenching) will be necessary for rectifying free-span sections where shoulder spans have been identified (see Table 5.19) and where additional pipeline stabilisation (at the ridge of the continental slope) may be required as shown in Table 5.20. It will be carried out by lowering the pipeline sections in question below the natural seabed level using post-installation trenching techniques. Post-lay trenching can be done by various means. Some equipment is self-propelled, others pulled by a surface vessel, and some make contact with the pipeline, whereas others avoid direct contact and loads on the pipeline. The method to be applied depends on water depth, soil conditions and burial depth to be achieved. The trenching methods can be grouped into three main categories; jetting, mechanical cutters and ploughs. The final decision on which method to be employed will
depend on the appointed installation contractor and subject to further detailed design. Each option requires a support vessel which will be equipped with special equipment to operate the ROV trenching equipment.

The jetting technique lowers the pipeline below the seabed surface through a combination of lateral excavation and high pressure water jetting to displace the sediment from under the installed pipeline. The pipeline then descends into the excavated space below it. If necessary, the displaced sediment may be pumped over the preceding section of the pipeline to backfill the trench. This method minimises displacement of sediment and associated benthic organisms and requires no temporary or permanent disposal of excavated sediments.

Mechanical cutters cut the soils under the pipeline to gradually lower it under the seabed surface. Mechanical cutters are normally heavy pieces of equipment fitted with crawlers that allow the cutter to crawl along the surface of the pipeline. This tool typically consists of cutter discs and suction pumps at the rear of the tool that push the excavated soil away from the trench. A mechanical cutter requires a support vessel to lower it into the water and position it accurately over the pipeline.

The ploughing technique uses a relatively large structure which is pulled over the seabed, which lifts the pipeline, cuts the soil and deposits it at the side of the trench and finally lowers the pipeline in the created trench. The trench can be left to backfill naturally or the deposited soil can be replaced on top of the pipeline in a successive operation by a backfill plough. A plough requires a support vessel with a large bollard pull and a large lifting A-frame.

At each span correction location to be trenched (shown in Table 5.19) it is anticipated that the pipelines will be lowered to a depth of approximately 1 m below the seabed surface. The width of seabed surface impacted by post-installation trenching will depend on the method employed, however it is anticipated to be approximately 20 m.

**Mass Flow Excavation**

Alternatively, MFE, as described in the Pre-Installation Seabed Intervention Requirements section above, could also be used for post-installation pipeline lowering / burial into the seabed. If MFE is used the management of change process described in Section 5.11 will be followed if it is deemed that this change may affect the results of the ESIA Report.

**Backfilling of Trench with Gravel / Rock**

As shown in Table 5.20, some areas of the pipeline located on the ridge of the continental slope may require post-lay trenching and backfilling of the trench to improve the stability of the pipeline. Backfilling of the trench with imported gravel / rock will be undertaken using a fall-pipe vessel as described in the pre-installation seabed intervention requirements section above. It is conservatively estimated that a total of approximately 64,000 m³ of gravel/rock will be required to backfill the four pipeline trenches.

**Rock Dumping**

Rock dumping is required to cover the pipelines at certain sections of the pipeline route where there is a risk of damage from potential rockfall (see Table 5.21). Rock placement will be
undertaken using a fall-pipe vessel as described in the pre-installation seabed intervention requirements section above. It is conservatively estimated that a total of approximately 27,000 m³ of rock will be required to meet rockfall protection requirements.

The exact extent of these post-lay seabed intervention measures may be adjusted during the detailed design stage, and will be further reviewed after the pipeline has been installed and surveyed. However, any changes are anticipated to be minor and are not anticipated to alter the results of this ESIA Report. Should any major design changes be required which may affect the results of the ESIA, the management of change process described in Section 5.11 will be followed.

A safety exclusion zone of approximately 0.5 km (0.3 NM) radius for rock placement or mattress installation vessels will be adopted during construction to avoid incident with marine traffic.

5.3.6.6 Crossings of Existing Subsea Infrastructure

No existing pipelines will be crossed by the Project offshore pipelines. However, the offshore pipeline route will cross six subsea cables. Three cables have been identified on the continental slope (one in-service and two unknown) and two in-service cables have been identified on the abyssal plain, the final cable was laid on the abyssal plain in 2013. The locations of the first five cables listed have been confirmed by ROV surveys carried out during Front End Engineering Design (FEED). The location of the latest telecommunication cable, laid in 2013, has also been confirmed since completion of FEED. An overview of the six known cables and their operators is provided in Table 5.21 and the crossing locations are shown in Figure 5.34.

The in-service Feodosiya (Ukraine) to Novorossiysk (Russia) cable is thought to be one of the three cables on the continental slope; however, it is unclear which of the three cables it actually is as the other two cables are located in close proximity. The status (in service or out-of-service) of these other two cables (Identified Cable No. 1 and No. 2) is presently unknown, however a number of cable breaks in Identified Cable No.2 were observed during ROV surveys. Therefore, it is assumed that this cable is out-of-service. The two confirmed in-service cables on the abyssal plain are the Black Sea Fibre Optic Cable (BS-FOCS) and Italy-Turkey-Ukraine-Russia (ITUR). The new cable is the Anapa-Dzhubga-Adler telecommunication cable that will be operated by Upravlenie Perspectivnyh Tehnologiy.

In addition, two further new telecommunication cables between Myskhako (City of Novorossiysk) – Cape Utrish and Cape Utrish – Cape Zhelezny Rog are understood to be planned for development in future although no route specific information has been obtained. These two cables are not shown in Table 5.22 and Figure 5.34.

Crossing Agreements

Known owners of active cables were approached with the aim of reaching mutual crossing agreements covering liabilities and procedures for crossing methods. According to the agreements, South Stream Transport will be required to provide crossing designs and installation procedures to the satisfaction of the owners prior to installation of the pipelines.

The crossing agreements used by South Stream Transport with the cable operators will be based on the guidelines prepared by the International Cable Protection Committee (ICPC) (Ref. 5.10), which are used worldwide for telecommunication cables.

Cable Crossing Techniques

For the in-service cables on the Russian Slope (assumed to be Identified Cable No.1 and the Feodosiya - Novorossiysk Cable), the identified cables are in free span at the location where they are crossed by the Project pipelines.

For the out-of-service cable on the Russian slope (assumed to be Identified Cable No.2), 150 m of the cable either side of the crossing location will be cut (after obtaining final permission from cable owner/authority). The cut cable will be removed from the pipeline corridor prior to pipeline construction and recovered and disposed of in an environmentally friendly manner as proposed by the ICPC. To ensure that the cut cable could not return to the pipeline corridor during the design life of the pipeline, the cable ends will be weighted with clump weights.

For the BS-FOCS, ITUR and Anapa-Dzhubga-Adler cables, the cable crossings will be constructed to ensure that the pipelines and cables remain at a safe distance from each other. The support height is selected in order to guarantee the agreed minimum vertical separation between the cable and the pipelines. The vertical separation between the pipelines and existing cables will be a minimum of 0.3 m for the BS-FOCS and Anapa-Dzhubga-Adler cable and 0.5 m for the ITUR cable (as specified by the owner Rostelecom) during the design life of the
pipelines, taking into account settling of the pipeline and support settlement in the seabed as well as further settlement by the cables. The separation distance will also take account of free span vibrations, where this is applicable. This will ensure that the cables are not unduly stressed or loaded by the pipelines passing over them.

The cable crossing is achieved by elevating the pipeline by supporting it with rigid concrete mattresses or mud mat structures either side of the cable. The use of mud mats will be adopted if the soils are deemed too soft for the use of concrete mattresses.

It is anticipated that crossings of the BS-FOCS, ITUR and the Anapa-Dzhubga-Adler cable, which are located on the abyssal plain will be crossed using mud mat structures to provide the vertical support for the pipelines due to the soft sediments present at the cable crossing locations. This crossing method involves installing crossing supports (mud mats) on both sides of the existing cables prior to pipeline installation. It is anticipated that each mud mat will have base dimensions of 10 m x 5 m and an approximate submerged weight of 10 tonnes. The crossing support will be installed parallel to the existing cables with a distance of 10 m from centre of support to the existing cable; however the distance of the cable from the edges of the support should be 2 m as a minimum. The minimum height of the crossing supports will be specified accordingly during the detailed design process.

The final crossing designs will be subject to agreements between South Steam Transport and individual cable owners. However, an indicative illustration of the crossing layout for the BS-FOCS and ITUR cables is shown in Figure 5.36.

**5.3.6.7 Nearshore and Offshore Construction Material Use**

**Use of Resources**

**Materials**

During construction of the nearshore and offshore section pipelines a variety of materials will be required. An estimate of the quantities of the main materials to be consumed is shown in Table 5.23. Quantities are approximate and subject to final optimisation.

**Fuel**

At sea, fuel and refuelling is referred to as bunker and bunkering, respectively. Where practical, vessels deployed in the Project area will use light fuels such as Marine Diesel Oil (MDO) or Marine Gas Oil (MGO). Sulphur content in fuel will be in compliance with requirements of Annex VI – 2008 to the MARPOL 73/78 Convention and any national legislation. Some vessel bunkering may be undertaken at support ports (most likely Novorossiysk) in Russia. The bunkering for some vessels (e.g. PSVs) will be undertaken at the marshalling yards in Bulgaria, as these vessels will be making return trips. However, for vessels located continually at sea (e.g. the pipe-lay vessel), the bunker will be pumped into the ships’ tanks by the bunkering tanker. All bunkering activities will be undertaken in accordance with the Vessels and Marine Transport activity-specific CMP, which will be developed as part of South Stream Transport’s ESMP. The CMP will contain activity-specific requirements, to be met by both South Stream Transport and the appointed contractors (and sub-contractors). Further details on the Vessels and Marine Transport CMP and South Stream Transport’s ESMP are described in Chapter 22 Environmental and Social Management. Estimates of the average daily fuel consumption during the construction phase of the nearshore and offshore sections are provided in Table 5.24.

Chapter 5 Project Description

*Water Consumption*

During construction of the nearshore and offshore section pipelines water will be required for domestic purposes on-board the vessels (this includes drinking water, washing, cooking, laundry and general vessel cleaning) and industrial use (various uses during pipeline fabrication process). Although some of the vessels listed in Table 5.16 and Table 5.18 may possess desalinisation equipment (distillation or reverse osmosis) to produce freshwater, it is assumed for the purposes of the ESIA that freshwater will be supplied by tankers. Bottled water may be provided for drinking purposes. Water requirements associated with the terrestrial construction activities associated with nearshore construction are included in Table 5.11. Water requirements for hydrotreating activities are described in Section 5.4.

5.3.6.8 Summary of Waste Generated during Construction of Nearshore and Offshore Sections

There are a number of activities during the Construction and Pre-Commissioning Phase of the nearshore and offshore sections that have the potential to generate waste. Table 5.26 presents a summary of the waste types anticipated to be generated using FWCC codes to categorise waste types. For each waste type, a likely range is estimated for waste volumes arising from the installation of the nearshore and offshore section pipelines. It also includes wastes (such as Monoethylene Glycol (MEG)) generated during the pre-commissioning activities (excluding hydrotest seawater) for the landfall and nearshore section pipelines described in Section 5.4, as the MEG shall be collected by marine vessels. A more detailed breakdown of the waste generated during construction of the nearshore and offshore section pipelines is presented in Chapter 18 Waste Management.

Should any of the vessels use desalinisation equipment to produce freshwater, the waste brine solution will be discharged to sea. Brine from the distillation and reverse osmosis processes must not contain or come in contact with machinery or industrial equipment, toxic or hazardous materials, or wastes. If brine does become contaminated by such materials, the brine will be transferred to a support vessel and disposed of properly onshore.

All wastes generated will be handled and disposed of in accordance with applicable Russian waste policy and MARPOL requirements. The locations of potential waste disposal facilities for waste generated by the Project at sea that needs taken ashore for disposal are shown in Figure...
5.9. However, it should be noted that no decisions as to which of these sites could or may be used have been taken at this time and will be subject to further investigation. Further information on waste generation and management is described in Chapter 18 Waste Management. Waste water in relation to pre-commissioning tests is described in Section 5.4.

5.3.6.9 Summary of Nearshore and Offshore Emissions to Atmosphere

Table 5.28 presents the greenhouse gas (GHG) (i.e. $\text{CO}_2$) and non-GHG emissions predicted to be generated from the installation of the nearshore and offshore pipeline sections for a single pipeline, based on the expected vessels and number of days of operation outlined in Table 5.16 and Table 5.18. The emission estimates sources include marine equipment supporting microtunnelling activities in the nearshore section but excludes pre-commissioning activities (Section 5.4). Further information on emissions to atmosphere is provided in Chapter 9 Air Quality.

5.4 Pre-Commissioning Phase

5.4.1 Overview

After each pipeline has been installed a number of activities, known as pre-commissioning activities (as illustrated in the construction schedule shown in Figure 5.7), will be undertaken to ensure that the pipelines meet operational requirements. The primary objective of these activities is to verify that the pipeline has been laid without significant defects and that it is in a suitable condition to be filled to transport the gas at the anticipated pressure and to deliver the gas to the required specifications. The equipment required for the pre-commissioning activities will be used for cleaning, gauging, hydrotesting and drying of the installed pipelines.

The pre-commissioning approach for the Project involves hydrotesting of the landfall facilities and landfall and nearshore (to 30 m water depth) sections of the pipelines only. Hydrotesting (a hydrostatic test) involves filling the pipelines with water which is then pressurised to a level in excess of the design pressure of the pipelines to test the strength of the pipeline and confirm that there are no leaks.

The offshore section of the South Stream Offshore Pipeline (from 30 m water depth in Russia to approximately 36 m water depth in Bulgaria) will not be hydrotested. A traditional hydrostatic test pressure may cause lateral buckling all along the South Stream Offshore Pipeline and, as a
result, the risk to the pipeline integrity may not be as low as reasonably practical. Furthermore, waiving of the hydrostatic test for the South Stream Offshore Pipeline presents various environmental and technical benefits, as follows:

- Costly and time consuming effects of pipeline flooding and dewatering operations are eliminated and any adverse environmental effects associated with the discharge of the test water from the full length of the Pipeline will be avoided;
- The construction schedule is shortened thereby reducing the duration of disturbance and temporary land use requirements;
- The potential adverse effects to the environment of lateral buckling (loss of containment) which may be caused by the relatively high hydrostatic test pressure will be eliminated, which will also result in elimination of the risk to the pipelines due to this failure mode; and
- Absence of flooding, dewatering and hydrostatic testing minimises the volumes of water, fuel and chemicals required and associated emissions and discharges to the environment.

Hydrotesting has been thoroughly investigated and intensively discussed with DNV (DNV are contracted by South Stream Transport for the verification of FEED and pre-qualification test of line pipe, buckle arrestors, coating and anodes for the Project) during the FEED design stage in 2012. The hydrotest for the pipelines in more than 345 m water depth is allowed to be waived according to DNV-OS-F101 (2010), Section B204. In addition a Concession Request has been approved by DNV for pipelines in water depth between 30 m and 345 m provided the following additional requirements are fulfilled:

- Safety class “High” shall apply for the installation and tie-in of the pipeline between 30 m and 345 m water depth;
- Subsea leak inspection by ROV shall be performed as soon as practicable following the start of operation of the pipelines;
- The allowable defect sizes for the girth welds shall be more restrictive than that permitted by the Engineering Critical Assessment; and
- The local incidental pressure (level of pressure that occurs incidentally at which safety devices operate) at 30 m water depth on the Bulgarian shelf does not exceed 291 bar.

All pre-commissioning activities will be undertaken in accordance with the requirements of South Stream Transport’s Pre-commissioning CMP. Details of the CMPs are described in Chapter 22 Environmental and Social Management.

5.4.1.1 Hydrotest Sections

Each pipeline will be hydrotested separately between a temporary PIG launcher/receiver fitted to the pipeline just downstream of the landfall facilities fence and the edge of the nearshore section at 30 m water depth where a tie-in between the nearshore and offshore pipelines will be made. During the installation of the nearshore section pipelines, a temporary subsea test head will have been welded to the ends of the pipelines to enable pre-commissioning tests to be undertaken. The temporary subsea test head will be designed to contain and launch flooding, cleaning and gauging PIGs towards the onshore PIG traps and to receive dewatering PIGs sent from the temporary PIG launcher/receiver located at the landfall facilities.
The landfall facilities themselves, upstream of the temporary PIG launcher / receiver location will be cleaned, hydrotested and dried separately from the landfall section pipelines.

The offshore section of the pipeline will not be hydrotested as described above. However, following the completion of pre-commissioning tests of the nearshore and landfall sections in Bulgaria and in Russia, and pipeline tie-ins at the 30 m water depth in Russia and approximately 36 m water depth in Bulgaria, the pipeline will undergo cleaning, gauging and drying between the temporary PIG launcher/receiver at the fence of the landfall facilities in Russia and a temporary PIG launcher/receiver located at the fence of the landfall facilities in Bulgaria.

5.4.2 Landfall and Nearshore Section Pipeline Testing and Pre-commissioning (Hydrotesting)

The pre-commissioning of the landfall and nearshore sections of each pipeline will be undertaken separately. The pre-commissioning of each pipeline will take approximately four weeks to complete (including mobilisation of the pre-commissioning spread). There is a gap of approximately three months between the pre-commissioning of each pipeline.

In order to undertake the pre-commissioning test, a suitable offshore support vessel will be mobilised to the tie-in location at 30 m water depth. The vessel will be equipped with a diving or ROV spread to deploy and connect a down line (hose) between the vessel and the subsea test head. Pre-commissioning tests of the landfall and nearshore section pipelines will use seawater.

A flooding, gauging and hydrostatic testing spread will be installed onboard the support vessel. This pre-commissioning spread will enable water supply, water treatment, flooding and testing of the pipeline. PIGs will also be launched from the subsea test head towards the PIG launcher/receiver located at the fence of the landfall facilities.

The terrestrial pre-commissioning equipment (compressors, water storage tanks etc.) will be located within the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E) (shown in Figure 5.10) and connected to the temporary PIG launcher/receiver via a series of hoses. In order to reduce noise pollution from the equipment, a sound wall comprising temporary noise attenuation panels which will surround the rotating assets, may be used. These panels shall be designed and built with high noise absorption characteristics.

5.4.2.1 Cleaning and Gauging

Typically, cleaning and gauging are performed as a single operation together with flooding. It is expected to take approximately three hours to flood each pipeline. Upon connection of the vessel based spread to the subsea test head, a PIG train(s) is inserted to the pipeline to clean and gauge the pipeline and remove construction debris. The PIG trains are pushed through the pipelines to the onshore PIG launcher / receiver near the landfall facilities by pumped seawater (drawn from the Black Sea), which has been chemically treated and filtered.

Diesel driven water supply pumps with a capacity of 25 cubic metres per minute (m³/minute) will be used to extract water from the sea via two temporary 6-inch hoses whose intakes are supported by buoys and suspended approximately 3-5 m above the seabed in a suitable
offshore location near the tie-in location at 30 m water depth. The suction hoses will be equipped with suitable strainers (2 mm screen mesh) to prevent coarse debris or sea life from entering the suction hose. Water will be collected in a break tank (water tank fitted with filter systems) on board the supply vessel. From the break tank, water will be pumped through a filtration skid to remove all particles larger than 50 microns. The filtered water is then injected with an oxygen scavenger (sodium bisulphite)\(^4\) to prevent internal corrosion of the pipeline prior to dewatering at an injection rate of 250 parts per million (ppm). It is anticipated that approximately 452 litres (l) of oxygen scavenger will be necessary per pipeline.

Diesel driven flooding pumps with a capacity of 25 m\(^3\)/minute and suitably sized downlines will be used to inject the filtered and chemically treated seawater directly into the subsea pipeline to push the cleaning and gauging PIGs.

A valve will be open on the onshore test head during the flooding operation, which will be connected to vents to vent air from the pipeline as it is filled with seawater. During the flooding operation, 100 m\(^3\) of seawater will initially be pumped into the pipeline followed by a cleaning and gauging PIG. A further 1,900 m\(^3\) of seawater will then be pumped into the pipeline. The first 100 m\(^3\) of water and debris (consisting of rust, coating and weld debris) in front and in-between the PIGs, as well as overfill water, will be captured in temporary onshore water storage (break) tanks.

On receipt of the PIG, the valves at both ends of the pipeline will be closed. The collected water will be stored for a sufficient length of time to allow the debris to settle to the bottom. It is expected that approximately 200 kg of debris may be produced per pipeline. The debris will be removed from site and disposed of through an approved waste disposal company. The 100 m\(^3\) of water will be temporarily stored and then pumped back into the pipeline during hydrotesting.

When all the cleaning and gauging PIG train(s) have been received into the temporary PIG receiver and the gauge plate(s) have been inspected for pipeline defects, the cleaning and gauging operation is complete.

The total seawater volume required for flooding, cleaning, gauging and hydrostatic testing will be approximately 2,000 m\(^3\) per nearshore and landfall pipeline section. Seawater intake information for each pipeline is summarised in Table 5.29.

\(^4\) Sodium Bisulphite is listed in OSPAR's PLONOR list.

5.4.2.2 Hydrotesting

Upon confirmation of successful cleaning and gauging of the pipeline, the pipeline will be hydrotically tested. Hydrotesting will be undertaken by pumping the 100 m³ stored treated seawater used to clean and gauge the pipelines back into the pipelines. Further treated seawater will then be pumped into the pipeline, using hydrostatic test pumps located on the support vessel, to raise the pressure in the pipeline to 330.8 bar (at +180 m reference elevation). The test pressure is based on the requirements set out in DNV Offshore Pipeline Standard DNV-OS-F101 requirements. In line with DNV-OS-F101 acceptance criteria, the pipeline pressure test will have a hold period of at least 24 hours.

Once the results of the hydrotest have been validated and accepted, the pipeline will be depressurised to ambient pressure. In the event that the hydrotest fails, the contractor will be required to detect the leak and then propose a repair method to South Stream Transport. The repair method will depend on the nature and location of the leak. Following agreement between South Stream Transport and the contractor of the repair method to be employed, the repair will be undertaken and the hydrotest repeated following the steps described above.
5.4.2.3 Dewatering and Drying

After a successful hydrostatic test, the pipeline will be dewatered and chemically conditioned (dried) using MEG. Dewatering/conditioning (drying) will be undertaken from the temporary PIG launcher/receiver at the landfall facilities towards the temporary subsea PIG receiver at 30 m water depth.

It is anticipated that dewatering will be performed by sending a PIG train consisting of two PIGs, separated by a batch of MEG from the temporary PIG launcher/receiver to the subsea PIG receiver to push out the seawater. The PIG train will be propelled by oil free, dry, compressed air provided by an onshore based compressor spread. In order to accomplish an average dewatering PIG speed of 0.5 metre per second (m/s) the compressor spread will consist of primary air compressors feeding air into an air drying unit. Each compressor will have a total capacity of maximum pressure of 34.5 bar and have a standard flow rate of 59.4 Standard Cubic Metres per Minute (Sm³/minute) at 20°C.

In order to remove and treat residue seawater from the pipeline wall during dewatering, a pre-calculated slug of MEG will be sent through the pipeline. The slug volume is estimated to be a worst case of 30 m³ based on the need to remove a 0.1 mm thick residual water film after pigging, and a required remaining water film mix in the pipelines of at least 97% MEG versus 3% water content after dewatering and conditioning. It is expected that approximately three hours will be required to dewater each pipeline.

During dewatering operations, the rate of discharge of treated seawater into the sea at the subsea PIG receiver will be 12.5 m³/minute, corresponding to a PIG speed of 0.5 m/s. Seawater will be disposed of from the temporary subsea test head (PIG receiver). The subsea test head is equipped with several valves and down line connection points to enable the launch and receipt of PIGs and water separately. The water exit point (located in the approximately the same location as the initial intake) will consist of a four or six-inch diffuser positioned approximately 1 m above the seabed, which is used to reduce the speed of water flow as it exits the pipe in order to reduce turbidity and possible creation of sediment plumes. The diffuser also act as an aerator, improving the oxygen concentration in the water, thereby compensating for the oxygen scavenging effect of the oxygen scavenger added to the hydrotest water.

The conditioning agent (MEG) will form part of the dewatering PIG train. MEG will not be disposed into the sea but will be pumped from the subsea test head to the support vessel via a down line. MEG will be received and stored in suitable secure tanks onboard the vessel and will be shipped to shore to be disposed or recycled by an approved waste handling company. The pipeline will then be depressurised to atmospheric pressure at a controlled rate through silenced vents.

Table 5.30 presents the expected volume and location of discharges associated with cleaning and gauging, hydrotesting and dewatering of the nearshore and landfall section pipelines. It should be noted that the water required for hydrotesting of the first pipeline will not be re-used for hydrotesting of the other pipelines and each pipeline will require separate water intake and discharge activities.

Should the detailed design process and discussions with the appointed contractor result in any changes to the dewatering and drying operations described here, the management of change...
process described in Section 5.11 will be followed if it is deemed that this change may affect
the results of the ESIA Report.

On completion of the drying operations, and prior to the introduction of gas, the pipeline will require purging with nitrogen to a pressure of 0.5 bar to avoid the formation of a potentially explosive gas/air mixture. When the oxygen level in the pipeline, as measured at each pipeline end, is equal to or less than 5% by volume, nitrogen purging is stopped, pre-commissioning of the pipeline is finished and commissioning can commence by introducing gas at the Russian end. Approximately 3,000 m³ (1.5 times the pipeline volume) of nitrogen will be injected to each pipeline from the offshore pre-commissioning spread or the temporary onshore PIG launcher/receiver. The nitrogen will be generated and injected into the pipelines by an electrostatic nitrogen membrane unit in conjunction with the air compressor spread. The membrane unit works by extracting nitrogen from the air and emitting the oxygen and carbon dioxide to the atmosphere. The units will generate nitrogen with a minimum purity of 95%.

The estimated equipment and vessels required for the pre-commissioning tests of the landfall and nearshore section pipelines are presented in Table 5.31.

### 5.4.3 Landfall Facilities Testing and Pre-commissioning (Hydrotesting)

The landfall facilities will undergo pre-commissioning tests separately from the landfall and nearshore section pipelines. The 24-inch and 32-inch pipelines within the landfall facilities may undergo pre-commissioning simultaneously or separately. For the purposes of this ESIA it is assumed that the pre-commissioning of the landfall facilities will be undertaken in two segments. The first segment to be tested is associated with the 32-inch pipelines and
associated pipework upstream of the landfall and nearshore section pipelines previously tested, and the second segment is associated with the 24-inch pipelines and associated pipework. A schematic showing the two segments to be tested is shown in Figure 5.37.

No PIGs are required for cleaning and gauging of the landfall facilities pipework. Checks for defects in the landfall facilities pipework are made during fabrication and construction of the pipework. The internal pipework will be cleaned by the water used for the hydrotesting and collected during the dewatering process. Each pipeline segment will have a temporary test head fitted which will be equipped with valves system to allow the connection of hoses and venting to take place during pre-commissioning activities.

5.4.3.1 Hydrotesting

It is anticipated that it will take up to six days to undertake the hydrotest of the pipework associated with a single 32-inch pipeline (first segment) and the corresponding 24-inch pipeline (second segment). Hydrotesting of each segment of the landfall facilities will be undertaken by pumping freshwater into the pipelines via the temporary test head from one end of the pipeline. It is anticipated that approximately 500 m³ of water will be required in total to hydrotest both 32-inch and 24-inch pipeline segments of the landfall facilities. The freshwater required will be imported by road tankers (lorries). The water will be pumped into the pipeline using a hydrostatic test pump to raise the pressure in the pipelines and associated pipework. It is anticipated that it will take up to two days to completely fill the pipework associated with a single 32-inch pipeline (first segment) and the corresponding 24-inch pipeline (second segment).

A valve will be open on one of the test heads during the flooding operation, which will be connected to a vent to vent air from the pipeline as it is filled with water. Once water is seen discharging from the vent, the vent point on the test head shall be closed. The 32-inch pipeline segment will be filled with water to raise the pressure in the pipelines to a maximum test pressure of 260 bar and the 24-inch segment pipelines will be pressured to a maximum of 450 bar (at +180 m reference elevation). The pipework will be pressure tested for a 24 hour period although the pipework will only be tested to the maximum test pressure for two separate one hour periods.

Once the results of the hydrotest have been validated and accepted, the pipelines will be depressurised to ambient pressure. In the event that the hydrotest fails, the contractor will be required to detect the leak and propose a repair method to South Stream Transport. The repair method will depend on the nature and location of the leak. Following agreement between South Stream Transport and the contractor of the repair method to be employed, the repair will be undertaken and the hydrotest repeated following the steps described above.

5.4.3.2 **Dewatering and Drying**

Following a successful hydrostatic test, the pipeline will be dewatered and dried using oil free, dry compressed air provided by compressors and heatless desiccant air drying units. The compressor will have a total capacity of maximum pressure of 34.5 bar and have a standard flow rate of 59.4 Sm³/minute at 20°C.

The dewatering process will clean the pipelines of any debris. Dewatering and drying will be performed by connecting a primary high pressure compressor and air drying unit to the temporary test head at one end of the testing segment and connecting a mobile tanker (lorry) or break tank to the test head at the other end of the testing segment to collect the hydrotest water. Oil free, dry, compressed air is then pumped into the pipeline to push out the hydrotest water and debris. It is anticipated that approximately 25 kg of debris will be produced by the dewatering process of the pipework associated with each 32-inch pipeline and corresponding 24-inch pipelines. The dewatering of the entire landfall facilities will produce approximately 100 kg of debris. The debris will be collected from the break tank (if used) and disposed of by an approved waste disposal company or alternatively, the mobile tanker (lorry) will collect the debris directly if a break tank is not used. As each pipeline within the landfall facilities will be hydrotested consecutively, it is possible that the filtered hydrotest water from the first pipeline segments (32-inch and 24-inch) will be collected and temporarily stored on site in tanks for hydrotesting the remaining three pipelines (32-inch and 24-inch segments) within the landfall facilities. If this is not possible, the filtered water (containing no particulates or chemicals) will be discharged by a hose into a sump constructed in an appropriate location within one of the temporary construction sites to allow the water to infiltrate into the ground.

Pumping of dry air into the pipeline segment will continue until the outlet dew point is approximately -50°C. On achieving the dryness criteria a 24 hour soak test shall be performed, followed by a further injection of the equivalent of two line volumes of dry air. A soak test is established industry practice of letting the pipeline soak towards the end of drying i.e. suspend the air injection and close-in the pipeline for 24 hours. Any remaining water will then be picked up by the undersaturated air and become visible when the flow of air is resumed. Drying of each pipeline (both segments) is anticipated to take approximately three days.

The hydrotesting, dewatering and drying of each pipeline (both segments) is anticipated to take approximately 23 days following set up of the pre-commissioning spread.

5.4.3.3 **Purging of the Pipelines with Nitrogen**

On completion of the drying operations, and prior to the introduction of gas, the pipeline will require purging with nitrogen to a pressure of 0.5 bar to avoid the formation of a potentially explosive gas/air mixture. Approximately 1,500 m³ of nitrogen will be required for purging the entire landfall facilities pipework. Bottled nitrogen will be brought to the construction site. The nitrogen will be injected into the pipelines in conjunction with the air compressor spread.

When the oxygen level in the pipeline, as measured at each pipeline end, is equal to or less than 5% by volume, nitrogen purging is stopped, and pre-commissioning of the pipeline is
finished. Purging of each pipeline (both segments) is anticipated to take approximately three days.

The estimated equipment required for the pre-commissioning activities at the landfall facilities are presented in Table 5.32.

5.4.4 Cleaning, Gauging and Drying of Whole South Stream Offshore Pipeline

As described in Section 5.4.1, there will be no hydrotesting of the pipelines between 30 m water depth in Russia and 36 m water depth in Bulgaria. Cleaning, gauging and drying of the South Stream Offshore Pipeline will be undertaken between a temporary PIG launcher/receiver at the fence of the landfall facilities in Russia and a temporary PIG launcher/receiver located at the fence of the landfall facilities in Bulgaria. The temporary PIG launcher/receiver used for each pipeline in Russia will likely be the same ones used for the pre-commissioning of the landfall and nearshore section pipelines. This cleaning, gauging and drying will be undertaken following completion of the pre-commissioning tests of the landfall and nearshore sections of the pipelines in both Russia and Bulgaria and completion of the pipeline tie-ins at the 30 m water depth between the nearshore and offshore pipeline sections. It should be noted that all wastes and discharges associated with cleaning, gauging and drying of the pipelines between Russian and Bulgaria will be collected and disposed of in Bulgaria.

The base case design, described here, assumes the cleaning and gauging PIGs will be transported through the pipelines from the temporary PIG launcher/receiver located at the Russian landfall facilities to the temporary PIG launcher/receiver located at the Bulgarian landfall facilities. However, it is possible that the outcome of the detailed design process and discussions with the appointed contractor may result in the PIGs being transported from Bulgaria to Russia. Should the direction that the PIGs are transported through the pipeline change, the management of change process described in Section 5.11 will be followed if it is deemed that this change may affect the results of the ESIA Report.
Cleaning, gauging and drying of the pipelines will be undertaken simultaneously using PIG trains consisting of cleaning and gauging PIGs and batches of MEG to dry the pipelines. The activities and durations are summarised in Table 5.33.

<td>3</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>53</strong></td>
</tr>
</tbody>
</table>

The dry air compressor package will consist of combined compressor and booster units, air drying units (to ensure there is not excessive moisture in the compressed air), metering, associated piping, spools, hoses and instrumentation. Each combined compressor and booster unit (same design ratings as those shown in Table 5.31) will have a total capacity of maximum pressure of 32 bar and have a maximum air delivery flow rate of 58.6 SM$^3$/minute at 20°C. The compressor spread will be located within the Landfall Facilities Construction Site and Pre-Commissioning/Commissioning Spread (Site E).

To meet compression requirements, approximately 80 combined compressor and booster units and 20 air drying units will be required at the PIG launching location to transport the PIG trains required for cleaning, gauging and drying activities of each pipeline.

It is anticipated that approximately 800 m$^3$ of MEG will be required to clean and dry each pipeline. The MEG and debris from the pipelines collected in front and in-between the PIGs, will be captured in temporary onshore tanks located at the temporary PIG launcher/receiver in Bulgaria, to allow the debris to separate from the MEG. The MEG and debris will be disposed of by an approved waste disposal company. It is anticipated that approximately 17-18 tonnes of debris will be collected by the cleaning PIGs for each pipeline.

It is anticipated that 10-20 m$^3$ of water may form within the pipelines during construction and installation as a result of condensation. Drying of the pipeline will be undertaken as part of the single PIG train launched from Russia that will simultaneously clean, gauge and dry the pipeline. As per the cleaning process described above, for the landfall and nearshore section pipelines, the MEG will be collected in secure tanks at the landfall facilities in Bulgaria and collected by an approved waste disposal company for disposal.

As is the case with the landfall and nearshore section pipelines, on completion of the drying operations of the pipeline, and prior to the introduction of gas, the pipeline will require nitrogen purging to avoid the formation of a potentially explosive gas/air mixture. When the oxygen level is sufficiently low, nitrogen purging is stopped, pre-commissioning of the pipeline is finished and
commissioning can commence by introducing gas at the Russian end. Approximately 600,000 m³ (at atmospheric pressure) of nitrogen will be injected into each pipeline at the Russian landfall facilities using two large electrostatic nitrogen membrane units. This results in 400,000 m³ (assumed at 1.5 bar) of nitrogen being contained in each pipeline. Each pipeline will take approximately three to five days to fill with nitrogen.

The cleaning, gauging and drying of each of the four pipelines will be undertaken individually as they are completed. It is anticipated that all pre-commissioning activities of each pipeline between the temporary PIG launcher/receivers at the Russian and Bulgarian landfall facilities will take approximately seven weeks.

On completion of all pre-commissioning tests, the remaining pipeline tie-ins will be undertaken. This includes tie-ins to the “Expansion of the United Gas Supply System” upstream of the landfall facilities in Russia and tie-ins to the Receiving Terminal in Bulgaria being developed by South Stream Bulgaria AD (SSB) as part of the project known as “South Stream Pipeline System on the territory of the Republic of Bulgaria”.

5.5 Commissioning

The Project will be brought into service by the introduction of gas from the “Expansion of the United Gas Supply System”, only after all control and monitoring systems have been commissioned in facilities upstream of the Project in Russia (Gazprom’s Russkaya CS) and downstream of the Project in Bulgaria (SSB’s Receiving Terminal).

Each pipeline will be commissioned separately and come into operation separately in line with the schedule set out in Figure 5.7.

The first injection of hydrocarbon gas can be made behind a PIG, or directly, without the presence of a PIG. The objective of the gas injection step is to sweep out the nitrogen or any non-sale gas (if MEG is not allowed in the export gas, for instance). The presence of MEG will depend on whether or not MEG was used for the drying of the pipelines as described in Section 5.4. The volume of nitrogen gas within each pipeline is 400,000 m³ (assumed at 1.5 bar) and approximately 600,000 m³ to 800,000 m³ when vented to the atmosphere via the vent stack at the Project landfall facilities in Bulgaria.

After pre-commissioning is completed each pipeline will contain nitrogen and traces of water (estimated at 1 m³) and MEG (estimated at 106 m³) which has been used to dry the pipeline. The small volumes of water and MEG will not be vented but will exist as a thin layer of liquid against the walls of the pipeline. This thin MEG/water liquid film will be gradually entrained by the transport gas during the first days / weeks of gas transport operations. It anticipated that the small traces of MEG will be removed slowly from the pipeline at the Receiving Terminal in Bulgaria operated by SSB. These traces of MEG/water are not anticipated to have an impact on the operations of the Receiving Terminal.
5.5.1 Temporary Gas Heating Requirements

During the commissioning process the pressure in the South Stream Offshore Pipeline needs to be gradually raised from 1.5 - 2 bar (the settle out pressure after pre-commissioning) to 65 - 100 bar (the pressure required for the Receiving Terminal in Bulgaria to start exporting gas to the downstream South Stream Pipeline System).

However, it is anticipated that the initial gas supplied from the Russkaya CS for commissioning purposes will not be supplied at 2 bar and a temperature ranging between -5 and +50°C but at pressure ranging between 100 bar (for the pipeline #1, December 2015) and 283.3 bar for subsequent pipelines (pipeline #2, December 2016; pipeline #3, June 2017, and pipeline #4, December 2017).

Therefore, the gas pressure will have to be reduced at the landfall facilities prior to gas injection. However, by reducing the pressure to 1.5 - 2 bar, this will result in the gas in the pipelines cooling substantially, in the range of 40 - 90°C, due to the temperature reduction caused by the Joule Thomson effect as it is transported across the Black Sea. Thus, to avoid the gas arriving at the Bulgarian landfall facilities below the intended operating temperature of -5°C, a temporary commissioning heater is required to heat the gas at the landfall facilities in Russia prior to it being injected into the pipeline. The requirement for gas heating is only necessary as a result of the low pressures necessary during commissioning and start-up.

To achieve a minimum inlet gas temperature of 0°C at a pressure of 100 bar at the landfall facilities, a 4 MW direct fire heater is required to achieve this level of pressurisation. For the case of a second pipeline (assuming the compressors at the Russkaya CS are already running for the operation of pipeline #1) the same heater duty can be used for compressor discharge temperatures above 35°C. Although for the start-up of pipelines #2, #3 and #4, the gas temperature from the Russkaya CS will be >35°C, the pressure differential is larger (>280 bar) than for the pipeline #1 (approximately 98 bar), which is enough to result in temperature at the pipeline inlet to be below 0°C when the valve is open (due to Joule Thomson effect). Hence, to avoid the temperature dropping below 0°C, the heater is required.

The 4 MW direct fire heater will be mobile and deployed to the landfall facilities when required for commissioning of each pipeline. The heater will occupy a footprint of approximately 12 m by 13 m, and it is anticipated it be connected to the FCV bypass line with double block and bleed isolations to removable flange plates. The heater will be gas powered and is anticipated to consume approximately 400 kg / hour. Emissions to atmosphere from the heater will be via 10 m high, 0.5 m diameter chimney. The heater will require to be in operation for approximately six days (allowing a further four days for the compressors to bring the pipeline pressure and flow up to normal operating conditions as described in Section 5.6.1).

A summary of the characteristics of the heater is shown in Table 5.36 and estimated emissions per pipeline are provided in Table 5.37.

5.5.2 Pipeline Gas Injection with a PIG

Injection of gas behind a PIG launched from the Russian landfall facilities will push the nitrogen towards the landfall facilities. Filling of the pipeline with gas is considered complete once the PIG has been recovered from the receiving trap in the landfall facilities.

During the early stages of the commissioning operation, a temporary valve within the Bulgarian landfall facilities is kept open so that the nitrogen is expelled from the pipeline at the receiving PIG trap and vented to the atmosphere via the vent stack as it is pushed through the pipeline by the PIG transported by the gas.

The duration required to sweep out the nitrogen mainly depends on the gas injection rate. Assuming a gas injection rate of 1.9 kilograms per second (kg/s), resulting in an average pigging speed of 3 m/s, it will take approximately five days for the pigging run to sweep out the nitrogen which will be vented from the vent stack within the Bulgarian landfall facilities. This will result in a venting release rate to atmosphere (at normal conditions) of 0.12 to 0.16 Million Cubic Metres per day (MMCM/day) from the vent stack.
5.5.3 Pipeline Gas Injection without a PIG

Alternatively, the gas could be injected directly into the pipeline, if the water dew point and the oxygen content requirements are met. The gas will displace the nitrogen, but a mixture of gases will form at the interface between the gas and nitrogen, forming what is commonly referred to as a mixing zone. The length of the mixing zone is estimated to be approximately three kilometres.

Assuming a gas injection rate of 14 kg/s, resulting in an average gas velocity of 22 m/s, it will take approximately two days to vent the nitrogen from the vent stack. This will result in a venting release rate to atmosphere (at normal conditions) of 0.3 to 0.4 MMCM/day from the vent stack located in the Bulgarian landfall facilities.

5.5.4 Pipeline Pressurisation

When the non-sale gas is swept out of the pipeline and the gas quality meets export conditions, the ESD valve at the Bulgarian landfall facilities end will be closed and pipeline pressurisation can commence. This pressurisation step will fill the pipeline up to an equalisation pressure of 65 bar (summer conditions) or 87 bar (winter conditions), making the South Stream Offshore Pipeline ready to start supplying gas to the Receiving Terminal. It is anticipated that each pipeline will take approximately ten days to fill with gas and commissioning activities will take approximately two weeks to complete.

During pipeline pressurisation quality control measurements will be carried out at the landfall facilities. Checks will be performed on all equipment used for detecting and sealing any gas leaks. In order to detect any leakage during start-up, there will be continuous metering of the pipelines for which the internal pipeline pressure exceeds the external pressure. Once the gas composition meter confirms that the gas at the landfall facilities meets the export gas specification, the South Stream Offshore Pipeline is ready to commence normal operation and gas transportation.

The entire filling and pressurisation operation will be documented in detailed work procedures prior to commencement of this activity. These procedures will be developed during the detailed design phase and will include all activities necessary to complete commissioning and achieve start-up status.

5.6 Operational Phase

5.6.1 South Stream Offshore Pipeline Operating Philosophy

The pipelines will have a maximum operating pressure of approximately 284 bar at the inlet to the landfall facilities. However, when the gas makes landfall in Bulgaria the operating pressure of the pipeline will have fallen to between 65 and 87 bar and the temperature of the gas will be approximately -5°C. The maximum daily capacity of each pipeline under normal conditions will be 47.9 MMSCM/day and a maximum of 63 BCM of gas will be transported by all four pipelines each year. The pipelines will be operated seven days a week, 24 hours per day.
The operating philosophy of the South Stream Offshore Pipeline is based on the principle of having a constant gas inventory (i.e. there is always gas stored in the pipelines) within the pipeline system. During normal operations, the gas inventory in each South Stream Offshore Pipeline is evaluated to range between 104 and 111 MMSCM with a pipeline throughput of 47.9 MMSCM/day.

The principle of a constant gas inventory relies on the proper, and synchronised, operation with the Russkaya CS in Russia and the Receiving Terminal in Bulgaria. The Russkaya CS and the Receiving Terminal in Bulgaria will determine the flow, pressure and temperature of the gas in the South Stream Offshore Pipeline during normal operation. The four individual pipelines will effectively be operated as a single pipeline and there will be no control system specific to each pipeline at the Russkaya CS or at the Bulgarian Receiving Terminal.

The South Stream Offshore Pipeline must operate within the pipeline inventory limits to maintain a safe and reliable system. A constant gas inventory guarantees that daily contractual gas transportation volumes (known as nominations) can be met when accurate flow measurement and reliable valve control are combined. The constant gas inventory also ensures that the time required to alter the gas supply rate in response to a decrease or increase in demand for gas can be met in the shortest time possible. This can be achieved by decreasing or increasing the pressure in the pipelines. The gas inventory of each South Stream Offshore Pipeline for various flow rates is summarised in Table 5.38. If for example, the flow rate was reduced to 60% of the maximum flow rate, it would take approximately three to five days for the flow rate to be ramped back up to 100%.

All four offshore pipelines will be operating at the same daily nomination, provided the discharge pressure of each offshore pipeline is the same. However, if necessary (for example due to a fall in demand for gas) it is possible to reduce the number of pipelines in operation as an alternative to reducing the flow of gas across all four pipelines.

The main process valves at the landfall facilities will be open during normal operations, and the landfall facilities will effectively only transport the gas from inlet to outlet. The landfall facilities
will include customised containers with monitoring metrology equipment, which will effectively act as the local control room. During normal operation there will be no workers based at the landfall facilities, however some workers will be required during pigging activities, start-up (following a shutdown), and maintenance activities.

5.6.1.1 South Stream Offshore Pipeline Parameter Monitoring

Pressure, temperature, flow, and gas composition (including water and hydrocarbon dew point) will be monitored by equipment at the landfall facilities and remotely in the CCR and BUCR by continuous real time monitoring of process conditions via the Supervisory Control and Data Acquisition (SCADA) system. The aforementioned parameters will be monitored by the SCADA system to estimate the gas inventory in each of the four pipelines (or however many are in operation) on a real time basis through the Pipeline Performance System (online simulator). There is no control system at the landfall facilities or, more generally, within the South Stream Offshore Pipeline to manage gas flows, pressures etc. Control of gas flows will be carried out at the upstream Russkaya CS and the downstream Receiving Terminal in Bulgaria.

However, as the South Stream Offshore Pipeline (including landfall facilities) is operated by a different organisation from the Russkaya CS (Gazprom Invest) and Bulgarian Receiving Terminal (SSB), it is necessary that certain process isolation, vent and blow down features are included in the landfall facilities. This is to ensure that South Stream Transport has independent means to stop gas from entering / leaving the pipeline, or to vent gas, as and when required (for example in the case of an emergency situation such as a pipeline leak). The vent system also allows for the pipelines to be depressurised for maintenance activities to take place if necessary.

To ensure that the gas inventory requirements do not deviate from the low and high band volumes (for example 104 and 111 MMSCM at maximum throughput), low and high alarms will be installed at the landfall facilities. Should there be an irregularity (or deviation), this information will be transmitted to the CCR, the Russkaya CS, and the Receiving Terminal in Bulgaria where the operators can carry out balancing operations (i.e. increasing or decreasing the gas inventory), which, in turn, may lead to an operational decision to shut down the gas supply to the Pipeline. Alarms will also be installed to detect changes in the gas pressures and temperatures.

Further to the alarm systems, trip systems will be installed at the landfall facilities. The trip systems will be designed to automatically shut down the South Stream Offshore Pipeline if minimum or maximum design standards (for gas pressure, temperatures or flows) are detected by the SCADA system. The automatic (emergency) shut down will ensure that the South Stream Offshore Pipeline is protected from damage.

The safeguarding features to be installed at the landfall facilities for normal operating conditions are shown in Table 5.39. In general, alarms will initially inform the operator of a problem to allow them to take the necessary operational activities to address the issue; the alarm would not however initiate a shutdown of the pipelines. If the problem persists, and a calculated trip setting is reached, the pipelines will be shut down automatically via the SCADA system.

---

**Leak Detection**

The South Stream Offshore Pipeline will be monitored by a Leak Detection System that operates on the basis of flow, pressure and temperature monitoring, thereby detecting gas losses on an automatic basis. These parameters are measured in continuous real time via the SCADA system. If the system detects a potential leak by detecting changes in the aforementioned parameters it will automatically alert the operators at the CCR and BUCR, however, it will not necessarily initiate an automatic shutdown.

It will be possible to detect leaks down to approximately 1-2% of gas throughput. Very small leaks offshore might not be detected by the system when they are smaller than the accuracy of the measurement and calculations. Both will be fine-tuned constantly during operation so the accuracy will increase with time and operating experience.

Information on emergency shut downs as a result of a confirmed leak is provided in Section 5.6.2. The location of a leak may be calculated to within an accuracy of approximately 100 m using the measured flow, pressure and temperature data recorded at the landfall facilities.

*Complete.*
5.6.2 Pipeline Shut Down and Restart Process

5.6.2.1 Pipeline Shut Down

During the operation of the South Stream Offshore Pipeline there may be a requirement to shut down the pipelines from time to time. Different types of pipeline shut down exist. These are:

- Process Shut Down (PSD), which corresponds to a stop of flow (closure of external ESD valves); and
- Emergency Shut Down (ESD), which applies to a F&G detection scenario (closure of external and internal ESD valves).

The shut down philosophy is based on the following principles:

- A constant gas inventory is to be maintained as much as possible so as to meet contractual requirements and also to allow a fast restart of the gas transport operations;
- Shut downs are to be performed in such a way so as to minimise the need for manned intervention for a restart;
- Best efforts will be used to minimise the need for shut downs for maintenance or modifications; and
- Gas will be vented only when a release is an absolute necessity.

The process safeguarding elements are used to shut down the South Stream Offshore Pipeline and, possibly, isolate the landfall facilities when there is an absolute necessity to do so. Some or all of the ESD/FCV valves which are not normally in use and are in the open position (or bypassed for the FCV) will close when a shut down occurs.

Process Shut Down

A PSD of the pipelines may be necessary during the lifetime of the South Stream Offshore Pipeline to carry out scheduled repairs or inspections. This is a planned event and will be undertaken under controlled conditions. The PSD will be carried out by operations at the Russkaya CS and at the Bulgarian Receiving Terminal. Normal shut down and ramp-down of gas flow is done by reducing the flow progressively to the required flow rate or by completely shutting down the flow in and out of the South Stream Offshore Pipeline at the Russkaya CS and Bulgarian Receiving Terminal.

Emergency Shutoffs

The landfall facilities will have local ESD and safety systems. Should there be an incident (unplanned event) such as those described in Table 5.39, the ESD system will be triggered and the pipelines will isolate themselves. The gas volume in the pipelines will then be automatically isolated from the landfall facilities, by closing the landfall facilities inlet and outlet ESD valves, thereby maintaining a constant gas inventory within the offshore pipeline.

During an ESD, the inlet ESD valve connected to the incoming 32-inch pipelines from the "Expansion of the United Gas Supply System" (within the landfall facilities), as well as the outlet ESD valves installed in the outgoing 32-inch pipelines are closed. The landfall facilities are kept...
pressurised during an F&G event to prevent further gas being potentially supplied to the location of the fire through venting.

The underlying principle is to stop the supply of gas to a fire (should there be one), and at the same time maintain a constant gas inventory within the pipeline. The inlet ESD valves in the incoming pipelines from “Expansion of the United Gas Supply System” as well as the outlet ESD valves in the outgoing pipelines from the landfall facilities will be closed.

Information on emergency pipeline repairs is provided in Section 5.6.5.

5.6.2.2 Restart Procedure

The restart procedure after a PSD or an ESD will depend on the pressure levels within the isolated systems. Pressure equalisation across the systems is planned to be achieved using bypass systems installed within the landfall facilities. The bypass systems consist of cast line heater (electric, in line circulation heaters that are designed to quickly and safely heat liquids and gases) to balance the temperature drop in the gas caused by choking, and a TCV that regulates the flow rate passing through the bypass line.

The restart can proceed if the following conditions are met:

- The cause of the ESD has been detected;
- The remedial actions have been completed (including eventual repairs and acceptance testing); and
- All safety related conditions have been met or exceeded.

After an ESD, the offshore pipelines settling out pressure is significantly lower than the pressure at the Russian landfall facilities and/or at the upstream Russkaya CS and is significantly higher than the pressure at the Bulgarian landfall facilities and/or at the downstream Bulgarian Receiving Terminal.

Before the gas transportation can be restarted by the upstream Russkaya CS in Russia and the downstream Receiving Terminal in Bulgaria, the ESD valves at the landfall facilities in Russia and Bulgaria will need to be reopened. The pressure equalising provisions (bypass system) are installed across each of the ESD valves (three per pipeline) for a quick restart. It is considered that it will take three days for pressure equalisation and ESD valve reopening at the landfall facilities in Russia and Bulgaria to be completed.

The general steps to be followed for a restart of the South Stream Offshore Pipeline for each shut down type are summarised in Figure 5.38. The restart procedure of the South Stream Offshore Pipeline will be completed when the pressure throughout the pipeline has equalised and when the ESD valves at the landfall facilities (both in Russia and Bulgaria) have been reopened.

Normal ramp-up of gas flow rate will be achieved by increasing the flow gradually until the targeted supply rate is reached. Such operation will be initiated and/or performed at the Russkaya CS and the Bulgarian Receiving Terminal simultaneously in order to maintain a constant gas inventory in the offshore pipelines. Such ramp-up will be driven by daily contractual supply requirements at the time.
5.6.3 Maintenance

5.6.3.1 External Pipeline Surveillance

Landfall Section Pipelines

Onshore cathodic protection monitoring will be undertaken manually with the monitoring undertaken at test posts distributed along the route of each pipeline at approximately 500-600 m intervals. The test stations will be on the centre line of each buried pipeline. At these test stations, a trained technician using a high impedance meter and copper sulphate half-cell will measure the cathodic protection potential. There will also be current measurement spans on each pipeline to measure current flow and direction for system balancing. At the transformer rectifier locations information on voltage and current may be collected manually or they may be connected to the Remote Terminal Unit (RTU) and SCADA.

Figure 5.38 Pipeline Restart Procedure

Nearshore and Offshore Pipeline Sections

The external condition of the subsea pipeline, including the condition of the cathodic protection system, will be monitored on a regular basis as set out in Table 5.40 using ROV or Autonomous...
Underwater Vehicles (AUV) and inspection technologies including sonar scans to visual (camera) inspections.

In accordance with the requirements of the concession granted by DNV to waive the need for hydrotesting the South Stream Offshore Pipeline in water depth deeper than 30 m, an initial ROV subsea leak inspection survey will be carried out along the pipelines as soon as practicable once the pipelines become operational and sufficient gas flow rates are achieved.

Critical sections of the pipeline route will be surveyed at more frequent intervals, initially on an annual basis and subsequently more or less frequently, depending on actual findings (e.g. growth of free span). Critical sections of the pipeline route may include:

- Steep slopes;
- Continental shelf break;
- Buried or trenched sections of the pipelines; and
- Any areas where free spans or other seabed anomalies may occur (based upon earlier inspections).

It is anticipated that the offshore surveys would involve vessels of characteristics such as the GSP Prince. Details of this vessel are shown in Table 5.18
5.6.3.2 Internal Pipeline Surveillance

Following the completion of pipeline gauging during pre-commissioning tests, further internal inspections of the pipelines using PIGs are not expected to be required until approximately five years after initial start-up and operation. The frequency of testing can be increased or decreased depending on the results of previous inspection runs, survey information and regulatory requirements. The proposed frequency of internal pipeline inspections is shown in Table 5.41.

</tbody>
</table>

Internal pipeline cleaning is not anticipated to be required due to the composition of the dry gas that will be transported through the pipelines. However, any cleaning that may be required will be undertaken using cleaning PIGs transported using gas. Gas flow rates in the pipeline will be reduced to approximately 60% of the maximum flow rate during pigging activities. Furthermore, a Pipeline Integrity Management System (PIMS) will be developed to control ongoing monitoring / maintenance during system operation, with a specific focus on corrosion control.

5.6.4 Landfall Facilities

Maintenance for the landfall facilities is equipment / vendor specific and therefore will not be confirmed until the detailed design phase is complete and contracts have been awarded for the provision of equipment. However, examples of the typical maintenance and frequency of maintenance and inspections is provided in Table 5.42.

5.6.5 Emergency Pipeline Repair

Although the probability of failure of a properly designed and installed deepwater pipeline is negligible, South Stream Transport will employ an Emergency Pipeline Repair Strategy (EPRS) for the South Stream Offshore Pipeline to be utilised in the event of damage to any of the pipelines. A repair philosophy has been prepared by South Stream Transport, which has led to the planned development of the EPRS by the pipe-lay contractor. The pipe-lay contractor will make available procedures and undertake emergency pipeline repair (permanent and temporary works) during the execution of the Construction and Pre-Commissioning Phase and into the first two years of the Operational Phase (up to a maximum of three years in the event of a repair) warranty period. From the end of the warranty period the EPRS will be controlled by South Stream Transport. This will either be done using the same EPRS or a different one that South Stream Transport may choose to adopt.

A key objective of the EPRS is to have a Repair Plan in place which reinstates the pipeline integrity and ensures the earliest possible and safe commencement of gas throughput. The Repair Plan has been prepared to provide a high level overview into recommended repair procedures and the relevant hardware and tools.

Repairs

For different types of damage, different types of repair and re-commissioning methods are applicable. Preparation of a pipeline for repair will be aimed at minimising or avoiding any impact on pipeline integrity, therefore avoiding water ingress. If water ingress is inevitable, or has already occurred, then dewatering/replacing salt or contaminated water with chemically treated water will be essential to stabilise the pipeline condition and to minimise corrosion whilst a case specific Repair Plan is developed and executed. The preferred approach will be to isolate the defected area (using plugs if pigging is feasible) and create a safe work environment for repair. Prior to re-commissioning a repaired pipeline, the pipeline must be cleaned, dewatered and/or conditioned to ensure the pipeline is clean, without defect and free of water. After a repair is made, whether it is offshore or onshore, the pipeline will be commissioned.
through pigging and drying and then gas can be re-introduced into the pipeline, thereafter 
resuming normal operating conditions.

The unplanned events and potential associated damage, which may occur to the pipelines is 
described in more detail in Chapter 19 Unplanned Events.

5.6.6 Land Use during the Operational Phase

Land will be acquired for Project infrastructure and to allow for operations, maintenance and 
emergency access during the operational life of the Project. The land take is summarised in 
Table 5.43.

Table 5.43 Permanent Land Use during the Operational Phase

<table>
<thead>
<tr>

<td>0.05</td>
</tr>
</tbody>
</table>

* 1.3 ha of the engineered cut and fill slopes area is located within the Pipeline RoW, therefore the area of engineered 
cut and fill slope that adds to the total permanent landtake is 3.53 ha.

The permanent RoW will be approximately 95 m wide (19 m either side of the centreline of the 
outermost pipelines) and 2.5 km long (0.1 km upstream and 2.4 km downstream of the landfall 
facilities) and will result in a permanent land take of approximately 23.75 ha, of which 1.3 ha is 
also part of the engineered cut and fill slopes required for construction of the Landfall Facilities. 
The permanent RoW is illustrated in Figure 5.39 and shown in Figure 5.40.

The pipeline permanent RoW will be indicated by land and aerial markers. Warning signs to 
indicate the presence of the pipelines will also be erected at specific locations along the pipeline 
route. Deep rooting trees or permanent crops will not be allowed to grow, however bushes and 
other shallow rooted vegetation will be allowed to grow naturally or will be planted. A track 
suitable for 4x4 vehicles only, will be present within the RoW for inspection purposes of the 
pipelines.

5.6.6.1 Onshore Safety Exclusion Zones

In addition to the permanent RoW there will be three Safety Exclusion Zones for the protection 
of public health and infrastructure from the centreline of the outermost pipelines in line with the 
requirements of Gazprom Standard STO 2-2.1-249 – 2008 for Main Gas Pipelines and in
accordance with the regulatory requirements set out for the Proekt (see Chapter 2 Policy, Regulatory and Administrative Framework). The proposed exclusion zones are as follows:

- Between 19 and 260 m from centreline of outermost pipeline: C- and E-class: no isolated buildings (1-2 levels), dachas, agricultural farms;
- Between 260 and 345 m from centreline of outermost pipeline: B-class: no cities, settlements, apartments of three levels or more, no developments / buildings with less than 100 people; and
- Between 345 and 410 m from centreline of outermost pipeline: A-class: no airports, railways station, no developments/buildings with population of more than 100 persons.

Operational environment and safety issues will be managed and monitored as part of the overall South Stream Offshore Pipeline Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS). Further information on the HSSE-IMS is provided in Chapter 22 Environmental and Social Management.

5.6.7 Offshore Exclusion Zones

To ensure that the subsea pipelines are not damaged by third party activities (e.g. dragged anchors, fishing gear, etc.) during the Operational Phase, exclusion zones will be put in place along the pipeline route to restrict activities that may damage the pipelines. These exclusion zones will reduce the potential impact on that part of the seabed, thereby they are a type of avoidance measure.

The proposed offshore exclusion zones will be agreed in consultation with the appropriate authorities. It is anticipated that the exclusion zone will extend to 0.5 km (0.3 NM) either side of the outermost pipelines from the microtunnel exit pit until the Russian / Turkish EEZ boundary (except for a section on the Russian continental slope where the pipelines diverge into two groups of two) as illustrated in Figure 5.41.

5.7 Pipeline Design Safety and Risk Assessment

An integrated HSSE-IMS has been developed in accordance with GIIP and in line with the requirements of ISO 14001:2004 (environmental management system) and OHSAS 18001:2007 (health and safety management system), as well as the Environmental and Social Management System requirements of the Project standards (principally the Equator Principles and the IFC Performance Standards). The main objective of the HSSE-IMS is to provide a robust framework for meeting the Project’s HSSE objectives during the entire Project lifecycle. The following section describes the approach to safety issues, a key component of the HSSE-IMS relating to the installation and operation of the South Stream Offshore Pipeline.

5.7.1 Construction, Installation and Operational Safety

Safety is a key priority for the Project during construction, installation and operation. Accordingly, a Health and Safety Plan will be prepared in order to reduce all risks to “as low as reasonably practicable” (ALARP).

Design hazards have been identified and assessed using internationally recognised tools throughout the FEED process. These tools include:

- Hazard Identification (HAZID);
- Environmental Issues Identification (ENVIID);
- Quantified Risk Assessment (QRA);
- Hazard and Operability (HAZOP);
- Hazard Construction (HAZCON); and
- Bowtie Analysis.

HAZID is a tool for safety hazard analysis used at an early stage of the Project to inform the FEED study. Risk workshops and HAZID studies have been held covering different aspects of the Project. The risks that have been identified have been addressed through design measures aimed at reducing either the likelihood or the consequences (or both) of the risks. Such measures have been developed during FEED and will be further developed during the detailed design phase of the Project. The HAZID is updated as the design evolves and develops, and when key design decisions are made and/or technology is selected. The risks identified as a result of the workshops and studies have been assessed qualitatively and this assessment will be followed by an overall risk assessment that will cover design, construction, installation, operations and simultaneous operations (SIMOPS), as required.

ENVIID is a tool for environmental issues identification and analysis used at an early stage of the Project to inform the FEED study. The ENVIID process aids the FEED study in identifying any significant impacts of the Project and the associated controls and mitigation measures to be implemented into the design to remove or reduce the impact.

QRA is a tool for calculating the individual and societal/group risks from major accidents or adverse events. QRA is used to establish the potential consequences of catastrophic events,
such as fires, explosions and gas releases, and the dimensions of exclusion zones and/or restricted areas where construction/building and occupation of land needs to be controlled.

HAZOP is a tool for the identification of process hazards in the design and operation of a facility or infrastructure. The HAZOP process comprises the systematic application of combinations of parameters (e.g. flow, pressure, temperature) and guide words (e.g. no, more, less) to produce deviations (no flow, less pressure) from the design intent or intended operational mode of the installation. Credible causes of these deviations are identified for each process section (node) and consequences of the deviations are assessed. The assessment consists of an examination of the pipeline design to determine whether the safety measures included in the design are sufficient to ensure that the pipelines are safe to operate, even under extreme or unusual conditions.

HAZCON is a safety study to identify and assess hazards before start of construction works. HAZCON 1 is generally carried out early in the project, prior to construction, to identify major hazards to client and contractor personnel, site visitors or the general public. HAZCON 2 is carried out to provide a detailed assessment of construction hazards, based on a significant completion of engineering design, engineering drawings, details of the RoW, construction implementation plan, landfall layout drawings and details of the marine/diving spread.

Bowtie analysis is part of the identification and management of key risks, and is used to identify risk controls, their effectiveness and corrective actions required. Before defining where to focus effort within the analysis, key risk areas are identified via other risk assessments and risk registers. The understanding of key risks highlights areas for which Bowtie analysis will be developed.

During the FEED process, design approaches and methods that minimise risk to personnel (construction, installation and operations personnel) as well as to the local community have been developed based on the results of the various risk assessment studies.

A FEED/Technical Risk Register is used to record all significant design HSSE risks, as well as technical risks related to construction and operations identified by the FEED study. The FEED/Technical Risk Register is established, managed and maintained by South Stream Transport, utilising inputs related to FEED risks from the FEED Contractor, and forms part of the overall Project Risk Register.

Major accident hazards (MAHs) during construction, installation and operation of the Project, in relation to the local community are addressed in Chapter 14 Socio-Economics. Plans for dealing with the effects on the community of construction, installation and operation of the Project such as increased traffic, transportation of hazardous substances, waste water discharge; solid waste disposal etc. will be managed by South Stream Transport and the respective contractors through a number of CMPs. Further information on the various Project CMPs to be implemented can be seen in Chapter 22 Environmental and Social Management of this ESIA Report.

5.7.1.1 Security of the Operational Facilities

As the landfall facilities are unmanned during the Operational Phase, security of the landfall facilities is primarily provided by perimeter security fencing, intruder alarms and the surveillance
of the real time CCTV by staff based in the CCR. The CCR will also have a constant and secure communication link with operational staff located at the Russkaya CS to be operated by Gazprom who may be alerted to an incident if necessary.

A Security Plan is currently being developed by South Stream Transport and a specialist company will be employed to advise South Stream Transport on a corporate level on security matters. South Stream Transport will appoint a security coordinator within the South Stream Transport Operations Team. The Security Plan will define the management and security measures to be employed for the Project. Further information on the management plans to be employed for the Project is provided in Chapter 22 Environmental and Social Management.

5.8 Labour and Procurement

5.8.1 Construction Phase

At the time of preparing this ESIA Report it was not possible to estimate the exact numbers of workers that will be employed during the construction of the Project. This information will become available when the detailed design of the Project has been completed. However, the maximum numbers of workers anticipated (at this present time) to be working on the Project during the peak of construction activity is presented in Table 5.44.

Table 5.44 Estimated Employment Levels during the Construction Phase

<table>
<thead>

<td>Landfall</td>
<td>330</td>
</tr>
<tr>
<td>Nearshore</td>
<td>544</td>
</tr>
<tr>
<td>Offshore</td>
<td>1,211</td>
</tr>
</tbody>
</table>

5.8.1.1 Hours of Working

In the landfall section it is anticipated that the standard working hours will be 0700 – 1900 Monday to Friday and 0700 – 1400 on Saturdays. However, for certain activities (for example pre-commissioning, commissioning and microtunnelling) there will be periodic requirements to work outside of these hours. Careful consideration will be given to the impacts of noise and vibration for any activities planned outside the normal working hours and no work will proceed without the necessary permits.

For construction and installation of the nearshore and offshore sections of the pipeline it is anticipated that work will be carried out 24 hours per day, seven days per week.

The majority of the construction work force required will be highly skilled and is anticipated to come from outside the local area. They will be lodged in the nearby towns and villages or on
the vessels that they work. Further information on the proposed workforce is provided in Chapter 14 Socio-Economics.

Workers will be transported to the landfall section construction sites by mini buses if required to reduce traffic movements and routes will be coordinated with local authorities. A number of cars and vans are also anticipated to be utilised to transport workers. These traffic movements are included in Table 5.8. The transport routes and potential impacts of traffic travelling to the landfall construction site will be managed through the Russian Landfall CMP, which will form part of South Stream Transport’s ESMP.

5.8.1.2 Worker Health and Safety

Occupational Health and Safety (OHS) for procurement, construction, installation and operations will be managed by South Stream Transport and their respective contractors. Internationally recognised procedures to assure the OHS of the workforce will be adopted along with the necessary equipment and training to make these effective.

The health risks to which workers are exposed are determined by a Health Risk Assessment (HRA). The HRA is the Hazards and Effects Management Process (HEMP) for health hazards, and identifies the health hazards and risks (physical, chemical, biological, ergonomic and psychological) in the workplace, and facilitates an occupational health needs analysis. The HRA determines if medical health surveillance is required for a job position that includes exposure to potentially harmful conditions or risks.

OHS procedures to be adopted by the Project include:

- Fitness-to-work Assessment;
- Management procedures; and
- First aid and medical emergency response.

Further information on OHS of the workforce is provided in Appendix 15.1 Occupational Health and Safety.

5.8.2 Operational Phase

There will be no full time workers employed for the Project during the Operational Phase of the Project, other than a workforce stationed permanently at the CCR and BUCR to operate the South Stream Offshore Pipeline. There will also be occasional periods when workers will be onsite during pigging operations and maintenance. Pigging operations will be undertaken by specialist contractors, whilst more general maintenance of electrical and monitoring systems is anticipated to be undertaken by employees based at the Russkaya CS being developed by Gazprom as part of the “Expansion of the UGS to provide gas to South Stream pipeline”. The operational performance of the South Stream Offshore Pipeline (including the Project pipelines and landfall facilities) will be monitored in real-time using SCADA from the CCR and BUCR in Amsterdam as described in Section 5.6.1.1.
5.9 **Decommissioning**

The expected service lifetime of the South Stream Offshore Pipeline is 50 years. The decommissioning program will be developed during the Operational Phase of the Project. It is likely that the technological options and preferred methods for decommissioning of such gas transportation systems as the South Stream Offshore Pipeline will be different in 50 years’ time. The decommissioning program will be developed during the Operational Phase of the Project. The status of the South Stream Offshore Pipeline at the time of decommissioning will also impact on the chosen decommissioning methods.

Under all circumstances, decommissioning activities will be undertaken in accordance with the international and national legislation and regulations prevailing at that time, and in liaison with the relevant regulatory authorities.

A review, and relevant studies if necessary, will be undertaken during the Operational Phase to confirm that the planned decommissioning activities utilise GIIP and are the most appropriate to the prevailing circumstances and future land use. The review will outline management controls and demonstrate that the decommissioning activities will not cause unacceptable environmental and social impacts. The decommissioning activities will also require all relevant approvals and authorisations from the Russian Government departments responsible at the time.

5.9.1 **Decommissioning of the Landfall Section of the Project**

During the Decommissioning Phase, activities on site associated with the removal of infrastructure will increase in intensity relative to those occurring during the Operational Phase of the Project. Of particular note are the potential environmental and social impacts associated with the following activities:

- The demolition of facilities and infrastructure;
- Equipment and vehicle movements; and
- Earthworks.

An environmental assessment will be conducted before decommissioning commences in order to confirm that the planned activities are the most appropriate to the prevailing circumstances. This assessment would aim to demonstrate that the decommissioning activities would not cause unacceptable environmental and social impacts and would lead to the development of specific management controls. Potential impacts associated with decommissioning activities may include the following:

- Erosion and sedimentation;
- Dust generation;
- Increased pressure on waste disposal facilities;
- Spills of hazardous substances;
- Disturbance to habitats; and
- Noise disturbance.
To what extent the following activities are undertaken will depend upon the agreed final use of the landfall section development areas, which will be defined in consultation with the relevant national and local authorities:

- Landfall facilities shall be removed;
- Access roads may be left in place depending upon the subsequent use of the land;
- Shallow foundations for infrastructure may be excavated, demolished and disposed of;
- Where piled foundations exist, these may be excavated to a depth of 1 m below the existing ground level and removed;
- Excavations resulting from the removal of foundations will be backfilled;
- Landfall section pipeline sections may be cleaned and re-used in connection with the offshore pipeline sections;
- For the pipelines within the microtunnels; if re-use is not feasible then they will most likely be cleaned, filled with inhibited sea water (seawater that has been treated with additives to inhibit its corrosiveness), sealed and left in place; and
- If re-use of the landfall section pipelines is not feasible then they will most likely be recovered and the steel recycled and the trenches backfilled and reinstated.

Prior to undertaking decommissioning activities, South Stream Transport will undertake a review of historical monitoring data and incidents on site that might have caused contamination.

Depending on the final land use agreed with the authorities for the landfall section area, all or part of the site may need to be rehabilitated. In such circumstances, South Stream Transport will also develop a monitoring program for completion criteria to verify that the sites are being returned to the agreed representative state. Completion criteria will be included for vegetation community composition, extent of weed infestation, erosion control and visual amenity of the site. These completion criteria will be determined in consultation with the local and national authorities.

In the event that the landfall section areas require to be returned to their original state (i.e. before the Project was constructed), stable landforms will be established and the site will be rehabilitated to an agreed level of representation of the pre-project plant communities based on agreement between South Stream Transport and the relevant authorities on these levels.

**5.9.2 Decommissioning of the Nearshore and Offshore Sections of the Project**

Current practices for the decommissioning of subsea pipelines involve either removing the pipeline or leaving the pipeline on the seabed after cleaning and filling it with water in combination with a program of planned monitoring to ensure safety for other users of the sea. The prevailing opinion is that leaving the pipeline in place results in the least environmental impact as over time the pipelines will become integrated within the seabed environment and their removal would disturb the habitats that have generated in the vicinity of the pipelines. A summary of the activities involved with the two options are described below.
Leaving the pipelines on the seabed will typically involve the following types of activities:

• Filling the pipeline with water;
• Pipeline cleaning by flushing with water and associated water displacement, collection and disposal;
• Sealing of the pipeline ends; and
• Monitoring surveys following decommissioning.

Removal of the pipelines from the seabed will typically involve the following types of activities:

• Vessel operations similar in nature to those required for construction of the pipeline;
• Seabed intervention works;
• Pipeline removal, recycling and disposal;
• Disturbance of the seabed and aquatic environment as the pipeline is recovered; and
• Logistics support offshore and onshore.

Factors to be considered when taking the decision on decommissioning methods for the Project include:

• The potential for re-use of the pipeline in connection with further developments will be considered before decommissioning, together with other existing projects (such as hydrocarbon storage, water outfall). If re-use is considered viable, suitable and sufficient maintenance of the pipeline will be investigated and ensured;
• All feasible decommissioning options shall be considered and a comparative assessment made;
• Any removal or partial removal of a pipeline shall be performed in such a way as to minimise the potential for any significant adverse effects on the marine environment;
• Any decision that a pipeline may be left in place should have regard to the likely deterioration of the material involved and its present and possible future effect on the marine environment; and
• Account shall be taken of other users of the sea.

Where it is proposed that a pipeline should be decommissioned by leaving it on the seabed for natural degradation (referred to as in situ decommissioning), either wholly or in part, the decommissioning program will be supported by a suitable study that addresses the degree of past and likely future burial/exposure of the pipeline and any potential effect on the marine environment and other users of the sea. The study will include the survey history of the pipeline, using appropriate data to confirm the current status of the pipeline, including the extent and depth of burial, trenching, spanning and exposure.

Determination of any potential effect on the marine environment at the time of decommissioning will be based upon scientific evidence. The factors to be taken into account will include the effect on water quality and geological and hydrographical characteristics, the presence of endangered or threatened species, existing habitat types, local fishery resources
and the potential for pollution or contamination by residual products from, or deterioration of, the pipeline.

The above serves as an example of general principles that should be applied during the decommissioning options decision-making process. It is foreseen that more directly applicable international or national guidelines are likely to be developed before the end of the lifetime of the Project (approximately 50 years) and that these will specify additional options that may need to be considered. The applicable regulations at the time of decommissioning will be adhered to.

5.9.3 Decommissioning Planning

It is envisaged that the process of developing detailed decommissioning management plans may be staged, initially outlining potential options and studies required for discussion with the regulatory authorities, and finally leading to agreed plans prior to the commencement of decommissioning. The content of the final plans will be dependent on the anticipated future land use. The plans will include methods and activities associated with the decommissioning of the offshore, nearshore and landfall sections infrastructure, including the transportation and final disposal or re-use strategy for Project components and wastes. Completion criteria will be detailed in the management plans. These completion criteria will be determined in consultation with the respective national and local authorities.

Documentation or processes addressing the issues outlined below will be developed to further support the implementation of detailed decommissioning management documentation:

- Incident reporting, recording and investigation;
- Chemical and hazardous substance management;
- Waste management;
- Dust management;
- Traffic management;
- Soils management;
- Health, safety and environmental site induction; and
- Spill contingency.

5.10 Summary of Total GHG Emissions to Atmosphere

Table 5.45 provides the total GHG emissions for the Project, the Turkish Sector of the South Stream Offshore Pipeline and the Bulgarian Sector. The total GHG emissions for the entire South Stream Offshore Pipeline are also shown. The methodology used to estimate these GHG emissions is contained within Appendix 9.4 of Chapter 9 Air Quality.

### 5.11 Management of Change Process

During the detailed design, Construction and Pre-Commissioning, and Operational Phases of the Project, there may be a requirement to amend design elements or processes which results in a deviation from that presented in this Project Description. The Project has a management of change process to manage and track any such amendments, and to:

- Assess their potential consequences with respect to environmental and social impact; and
- In cases where a significant impact is likely to arise as a consequence of the amendment or change, to inform and consult with relevant parties on the nature of the impact and on proposed mitigation measures, where practical and appropriate.

All design changes will be added to a register of changes, which will summarise the change, the assessment, and the justification for South Stream Transport’s actions.

The management of change process will be incorporated into the HSSE Management of Change Procedure, which is an integral part of the HSSE-IMS described in more detail in [Chapter 22 Environmental and Social Management](#).

6 Stakeholder Engagement

6.1 Introduction

This chapter describes the South Stream Transport approach to stakeholder engagement, its purpose and the regulatory context in which it occurs. It provides information about engagement activities undertaken to date for the ESIA and those that are planned for the future. This chapter also summarises the comments that have been made by stakeholders to date and how these comments are addressed within the relevant chapters of this ESIA Report.

In this chapter, the Environmental Impact Assessment (EIA) engagement process will also be referred to as this sets important context at the Russian national level and in doing this, shows how South Stream Transport has not only complied with national legislation, but also with Good International Industry Practice (GIIP). Although the national EIA and the ESIA process have been run separately in parallel, engagement activities for both processes are described in this chapter, as South Stream Transport will consider comments from stakeholders from both processes while completing the ESIA process.

This chapter is structured as follows:

- **Section 6.2** describes the national and international framework upon which the stakeholder engagement programme has been developed;
- **Section 6.3** describes the foundation of the stakeholder engagement programme, as well as the supporting documents and processes;
- **Section 6.4** outlines the stakeholder engagement activities for each phase of the Project lifecycle; and
- **Section 6.5** summarises comments, questions and recommendations received to date.

Stakeholder engagement (including dialogue, consultation and the disclosure of information) is a key element of project planning, development and implementation. Effective stakeholder engagement assists good design, builds relationships with local communities, and reduces the potential for delays through the early identification of risks and issues. South Stream Transport is committed to a transparent and respectful dialogue with stakeholders throughout the life of the Project.

The engagement approach for the Project includes a range of activities designed to consult stakeholders, using methods which take into account the varied interests that stakeholders may have in the Project as well as their location, language, culture, their access to information and the different opportunities to participate (e.g. through statutory consultation processes as well as through the ESIA process). The Project’s approach to stakeholder engagement includes making best efforts to ensure stakeholders are provided with adequate, timely and culturally appropriate information about the Project, the ESIA and consultation process. It also provides opportunities for stakeholders to ask questions, make comments and suggestions and raise any concerns that they may have. The Project’s approach to stakeholder engagement has been developed to align with the national legislative requirements and international standards.
Stakeholder engagement is an important element of the ESIA process in that it enables the ESIA Report to be informed by the interests and concerns of stakeholders, and provides opportunities for stakeholders to have those interests and concerns considered in decisions that may affect them. Effective engagement also helps to establish a relationship between stakeholders and the Project Proponent, South Stream Transport, which is based on trust and respect.

South Stream Transport has taken these principles into account in the planning and implementation of stakeholder engagement activities for the Project (Section 6.3).

### Terms to Know

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Consultation</strong></td>
<td>The process of sharing information, ideas and concerns in a two-way dialogue between project proponents and stakeholders, allowing stakeholders to express their views and for these to be considered in the decisions about project planning and implementation.</td>
</tr>
<tr>
<td><strong>Disclosure</strong></td>
<td>The process of making information available to stakeholders. Includes the publication of reports or documentation (in digital and/or paper formats), and announcements related to the disclosure process.</td>
</tr>
<tr>
<td><strong>Grievance</strong></td>
<td>Formal complaint by individuals, groups or organisations who feel they have been adversely affected by Project-related activities.</td>
</tr>
<tr>
<td><strong>Grievance Procedure</strong></td>
<td>Process of recording and addressing grievances so that they can be tracked through to a resolution.</td>
</tr>
<tr>
<td><strong>Mitigation</strong></td>
<td>Measures developed through the ESIA process to prevent, avoid, reduce or offset adverse impacts. Can also include measures to enhance beneficial impacts.</td>
</tr>
<tr>
<td><strong>Stakeholder</strong></td>
<td>Any individual, group or organisation potentially affected by a project, interested in, or with influence over, a project.</td>
</tr>
<tr>
<td><strong>Stakeholder Engagement Plan</strong></td>
<td>A Stakeholder Engagement Plan (SEP) forms part of the ESIA documentation and provides a plan and implementation strategy to guide stakeholder engagement throughout the Project lifecycle.</td>
</tr>
</tbody>
</table>

### 6.2 Regulatory Context

This section describes the regulatory framework that applies to the Project. The Project’s approach to stakeholder engagement considers both regulatory requirements and principles of Good International Industry Practice (GIIP), and seeks to:
Meet the legal requirements of the Russian Federation for public consultation and disclosure during the EIA process (described in Section 6.2.1);

Align with international standards and guidelines for financing (and GIIP), as related to ESIA, that provide a framework for public consultation and disclosure during the ESIA process (described in Section 6.2.2); and

Align with international conventions and protocols relevant to stakeholder engagement for the Project (described in Section 6.2.3).

The national EIA and international ESIA processes are illustrated in Figure 6.1. Consultation and disclosure requirements for the Russian EIA process have several features in common with stakeholder engagement processes for international ESIA. Both are based on the principle that those who may be affected by a project should be consulted.

South Stream Transport seeks to align the two processes, avoid duplication and ensure that where possible and permissible, the processes inform each other. The regulatory framework is further summarised in Chapter 2 Policy, Regulatory and Administrative Framework and the aspects of it that relate to stakeholder consultation are described in further detail in Section 6.2.

### 6.2.1 National Requirements

Consultation and disclosure requirements for the Russian national EIA process are outlined in Russia’s Federal laws and regulations. The relevant EIA regulation includes:

- Federal Law on Environmental Protection (2002, No.7-FZ);
- Regulation on Impact Assessment of Planned Economic or Other Activity on Environment in Russia Federation (adopted 2000, by Order No.372)\(^1\); and

\(^1\) The requirements of Order No. 372 are often read in association with the City Planning Code (2004, No.190-FZ) and with Government Enhancement ‘On the structure of design documentation sections and requirements to their contents’ (2008, No. 87).
In Russia, there are no regional or local laws relating to EIA procedure. Russian Federation law requires that an EIA be prepared as part of a package of technical and other information known as the “Proekt”, or project design. The project proponent then submits the Proekt to authorities for their review and approval. Public consultation is a mandatory part of the EIA process and involves the following main elements:
• **Terms of Reference (ToR) for the EIA** – preparation of the Terms of Reference for the Russian EIA, which is then disclosed for public review and comment (minimum 30 days);

• **Draft EIA** – publication of the draft EIA Report for public review and comment. The draft EIA Report is also the subject of one or more Public Hearings, at least 30 days after the initial publication of the report;

• **Public Hearings** – information about the proposed project and draft EIA is presented to the public. Legislation also states the draft EIA should be available for comments for at least 30 days after completion of Public Hearings; and

• **Final EIA** – the minutes of the Public Hearing are incorporated into the Proekt documentation for State Review, along with all comments, submissions and feedback on the draft EIA considered during finalisation of the EIA.

### 6.2.2 Standards and Guidelines for Financing

In addition to the EIA requirements described above and in line with international standards and guidelines for financing, the Project is being developed in accordance with financing requirements and GIIP. In relation to ESIA and more specifically, stakeholder engagement, the applicable standards are:

• The Organisation for Economic Cooperation and Development’s (OECD) Common Approaches to Environmental and Social Due Diligence (Ref. 6.1);

• The Equator Principles III (Ref 6.2; Ref 6.3);

• Japan Bank for International Cooperation (Ref 6.4); and

• The International Finance Corporation (IFC) Performance Standards (PS) (Ref 6.5).

All the standards and guidelines listed above require compliance with applicable national legislation, including laws implementing national obligations under international law.

Details of these international standards and guidelines as they apply to stakeholder engagement are provided below in sections 6.2.2.1 to 6.2.2.4.

#### 6.2.2.1 OECD Common Approaches

As detailed in Chapter 2, the Common Approaches for Officially Supported Export Credits and Environmental and Social Due Diligence (the ‘Common Approaches’) of the OECD (Ref. 6.1) provide guidance for considering environmental and social risks in decisions to offer official support for export credits.

In relation to stakeholder engagement, the Common Approaches recommend that:

• ESIA reports and related information should be made available to affected communities in language accessible to them for at least 30 days; and

• OECD member countries should encourage protection and respect for human rights and foster transparency, predictability and responsibility in decision-making by encouraging disclosure of ESIA information.
6.2.2.2 **Equator Principles III**

The second generation of the Equator Principles (EPII) provided guidance for stakeholder engagement in Principle 5: Stakeholder Engagement. For certain projects, the latest update to the Equator Principles (EPIII) provide further requirements for structured and culturally appropriate consultation undertaken with stakeholders (including affected communities; Ref. 6.2 and 6.3). By complying with the EPIII, a Project can ensure the informed participation of its stakeholders and be able to demonstrate how the concerns of affected communities have been considered in project decision-making.

The EP III states that a grievance mechanism should be developed to receive and facilitate resolution of concerns and grievances about the Project’s environmental and social performance. The Project must inform the affected communities about the mechanism during the stakeholder engagement process.

6.2.2.3 **Japan Bank for International Cooperation**

The focus of the Japan Bank for International Cooperation (JBIC) (Ref. 6.4) Environmental and Social Considerations Required for Funded Projects (*Chapter 2 Policy, Regulatory and Administrative Framework*) is generally aligned with that of the IFC Performance Standards. The purpose, according to the guideline, is to demonstrate that project proponents are undertaking appropriate environmental and social considerations, through various measures, so as to prevent or minimize the impact on the environment and local communities which may be caused by the projects for which JBIC provides funding, and not to bring about unacceptable effects.

Specific to Stakeholder Engagement, and in line with IFC standards described below, JBIC requires that projects must be adequately coordinated so that they are accepted in a manner that is socially appropriate to the country and locality in which the project is planned. For projects with a potentially large environmental impact, sufficient consultations with stakeholders, such as local residents, must be conducted via disclosure of information from an early stage where alternative proposals for the project plans may be examined. The outcome of such consultations must be incorporated into the contents of the project plan; and appropriate consideration must be given to vulnerable social groups, such as women, children, the elderly, the poor, and ethnic minorities, all of whom are susceptible to environmental and social impact and who may have little access to the decision-making process within society.

6.2.2.4 **IFC Performance Standards**

The IFC Performance Standards apply to private sector projects seeking financing from international financial institutions (Ref. 6.5), and also underpin many other financing guidelines

---

2 Category A and, as appropriate, Category B projects located in non-OECD countries, and those located in OECD countries not designated as High-Income, as defined by the World Bank Development Indicators Database. Category A projects are defined as those that have potential significant adverse environmental or social risks and/or impacts that are diverse, irreversible or unprecedented. Category B projects are defined as having limited adverse risks. The Project is considered a Category A Project.
(including the Equator Principles and the OECD Common Approaches). IFC PS 1 – Assessment and Management of Environmental and Social Risks and Impacts – sets out guidance for stakeholder engagement as part of project development.

IFC PS 1 states that project sponsors should promote and provide means for adequate engagement with communities affected by a Project, on issues that could potentially affect them. It also states that relevant information about environmental and social issues should be disclosed and disseminated and that communications (including questions, comments, suggestions and grievances) from affected individuals, groups, communities and other stakeholders should be responded to and appropriately managed.

IFC PS 1 also calls for the development and implementation of an Environmental and Social Assessment and Management System (ESMS) and a Stakeholder Engagement Plan (SEP). It focuses on the need to tailor engagement according to the expected scale and type of impacts and to make it appropriate to communities that may be affected by a project, as well as other stakeholders. This includes allowing disadvantaged and vulnerable groups to participate effectively.

In relation to information disclosure, PS1 requires project proponents to provide affected communities with access to relevant and understandable information about the project and the ESIA process and to provide them with opportunities to express their views on project risks, impacts and mitigation measures, and for the project proponent to consider and respond to these.

The requirement for a Grievance Procedure is also detailed in IFC PS1. A Grievance Procedure should be designed to receive and facilitate resolution of community grievances arising from project activities. IFC PS 1 also calls for periodic reports to be made to affected communities about issues of concern, including those identified through the consultation process or Grievance Procedure.

6.2.3 International Conventions

6.2.3.1 Aarhus Convention

The Convention on Access to Information, to Public Participation in the Decision Making Process and the Administration of Justice concerning Environmental Matters (the Aarhus Convention, adopted in 1998, Ref. 6.6) also includes provisions that relate to stakeholder engagement. It establishes public rights of access to environmental information and aims to promote public participation in decision making about environmental matters. Of the three host countries of the South Stream Offshore Pipeline, Bulgaria is the only one that has ratified the Aarhus Convention.

6.2.3.2 Espoo Convention

The United Nations Convention on EIA in a Transboundary Context (Ref. 6.7), sets out the obligations of signatory countries to assess the environmental impact of certain activities at an early stage of planning and lays down their general obligation to notify and consult each other
on all major projects under consideration that are likely to have a significant adverse environmental impact across boundaries.

The Convention entered into force on 10 September 1997. Of the three host countries for the Project, only Bulgaria has ratified the Convention. Therefore, for the South Stream Offshore Pipeline, Bulgaria is the Party of Origin for any transboundary consultation process with neighbouring countries that may be required. Consultation related to Espoo is described in the ESIA report for the South Stream Offshore Pipeline – Bulgarian Sector.

### 6.3 Approach to Stakeholder Engagement

South Stream Transport’s approach to stakeholder engagement is designed to comply with Russian legislation and to be aligned with the international standards and guidelines as described in Section 6.2. Accordingly, it provides a mechanism for stakeholders to be engaged during all phases of the Project. Within each phase of the Project, a range of engagement activities will be undertaken to address the needs of different stakeholders and stakeholder groups.

The main elements of the approach to stakeholder engagement are described in this section. Section 6.3.1 describes the Stakeholder Engagement Plan (SEP), which provides a framework for past, current, and future engagement activities. The SEP is the mechanism by which the principles and processes for stakeholder engagement, outlined in this Chapter, are implemented. Section 6.3.2 describes the process by which various stakeholders have been (and continue to be) identified. Section 6.3.3 discusses the ways in which stakeholders can provide feedback to South Stream Transport about the Project, and Section 6.3.4 presents the Stakeholder and Consultation Database (SCD), which is South Stream Transport’s central mechanism for managing and coordinating feedback received throughout the stakeholder engagement process. Finally, Section 6.3.5 introduces the Grievance Procedure for the Project.

#### 6.3.1 Stakeholder Engagement Plan

South Stream Transport’s SEP for Russia provides a stakeholder engagement framework for all phases of the Project, including Construction and Pre-commissioning, Operation and Decommissioning. The SEP is a ‘living’ document and is progressively updated as the Project moves through the various phases of planning and implementation. Further updates will be issued around key Project milestones, such as the disclosure of the ESIA Report, and the start of construction activities.

The SEP describes the way in which South Stream Transport:

- Identifies stakeholders;
- Develops and maintains positive relationships with stakeholders;
- Provides culturally appropriate, adequate and timely information about the Project and the EIA/ESIA process to stakeholders;
- Provides suitable opportunities for stakeholders to express their opinions and concerns in relation to the EIA/ESIA and Project development;
Enables compliance with Russian Federation regulations and alignment with international standards and guidelines for financing;

Ensures that Project decisions consider stakeholder priorities, views and concerns and that these are reflected in the EIA/ESIA and Project management decisions where appropriate; and

Will engage with stakeholders to establish and maintain dialogue.

The SEP provides an overview of the consultation and disclosure activities planned for the Project, including their purpose, timing, and the objectives of the activities. It provides information about consultation and disclosure activities that have already been conducted, as well as a roadmap for planned consultation and disclosure. It is regularly updated as the Project progresses and new information becomes available.

The SEP is published in English and Russian on the South Stream Transport website. The next update to the SEP will include more detailed information on the planned ESIA disclosure and consultation activities. The latest version of the SEP is always available on the South Stream Transport website at www.south-stream-offshore.com.

6.3.2 Stakeholder Identification

It is important to identify the Project’s stakeholders and understand how they may be affected, or perceive that they may be affected, so that engagement can be tailored to inform and appropriately address their views and concerns.

Stakeholders with an interest in the Project have been identified in several ways. These include:

- Drawing on the local knowledge of in-country environmental and social consultants;
- Feedback from consultations with stakeholders held to date;
- Desktop research including reviews of previous ESIA for relevant (by type or location) previous projects; and
- Scoping of anticipated impacts and receptors.

In addition, stakeholder engagement activities also help to identify and engage additional stakeholders and stakeholder groups.

When planning engagement activities, it can be helpful to group stakeholders based on common interests and characteristics. As such, South Stream Transport uses a number of “stakeholder categories” to help structure engagement activities for stakeholders of the Project. Stakeholder categories in the Russian Sector include:

- Landowners;
- Land users;
- Businesses and business associations;
- Fisheries and other marine area users;
- Government authorities (national, regional and local);
• Inter-governmental organisations;
• Community service and infrastructure organisations;
• Non-governmental organisations (NGOs);
• General public (including residents of Local Communities, and visitors to these communities);
• Academic and research organisations; and
• Media.

These stakeholder categories are described in Table 6.1 including a summary of the anticipated interests of these groups with respect to the Project (e.g. potential impacts, benefits, concerns) and how they have been engaged to date. Further detail on stakeholder engagement activities and stakeholder issues and concerns is provided in Section 6.4 and Section 6.5 below, while Appendix B of the SEP provides a full list of all identified stakeholders in Russia.
### Table 6.1 Stakeholder Categories and Identification

<td>Local diving clubs and businesses, and recreational marine users.</td>
<td>Diving and recreational boat clubs were notified of the publication of the Scoping Report and invited (by letter and phone) to a roundtable meeting for marine area users and local businesses.</td>
</tr>
<tr>
<td>Shipping, telecommunications and offshore oil-and-gas exploration companies also have an interest in accessing and using the marine area, although potential impacts on these companies were considered but have been ruled out (as described in Chapter 14 Socio-Economics).</td>
<td>Oil and gas exploration companies, including Rosneft, Exxon Mobil, and RN-Exploration. Shipping terminals/ports, including Temryuk Port and Novorossiyk Port.</td>
<td>Meetings and exchanges of information and data took place regarding the proposed Pipeline route and coordination of activities between the Project and oil and gas exploration and shipping/port companies.</td>
</tr>
</tbody>
</table>

**Government Authorities**

National authorities have specific interests in topic areas such as cultural heritage, tourism, transport, shipping and navigation, fisheries, and gasification and community development. Russian national government e.g. MoNRE, MoFA and various associated ministries and departments. National government authorities have been informed and consulted as part of the ESIA process, although formal engagement with the authorities is undertaken through the national EIA process. Engagement with various government departments responsible for topics such as environment, culture, tourism, transportation, safety, fisheries, archaeology and natural resources has been on-going throughout the EIA, ESIA and permitting processes.

</thead>
<tbody>
<tr>
<td>Russia media at national, regional and local levels.</td>
<td>Engagement with the media has occurred through press releases and announcements during key disclosure events, such as the publication of EIA and ESIA documentation. Three media roundtable meetings were also held, in Moscow and Krasnodar in November 2012 for the Scoping Report, and in Krasnodar in May 2013 for the Draft EIA Report, to enable members of the press to ask specific questions regarding the Project.</td>
</tr>
</tbody>
</table>

---

The stakeholders listed in Table 6.1 are examples of the groups and types of stakeholders engaged. However, a full list of all stakeholders engaged with the Project to date can be found in Appendix B of the SEP.  
** This applies to all stakeholders in Table 6.1.
Local Communities

As detailed in Section 6.2.2 (Standards and Guidelines for Financing), international standards and guidelines state that appropriate consultation should be undertaken with affected communities.

For the purposes of this Report and the SEP, certain communities are referred to as ‘Local Communities’, which have been identified either because they are the closest communities to the Project Area or, in the case of Rassvet and the town of Anapa, because they have the potential to experience impacts associated with construction and accommodation of the Project workforce.

In the Russian Sector of the Project, the Local Communities have been identified as:

- Town of Anapa;
- Gai Kodzor;
- Rassvet;
- Sukko;
- Supsekh; and
- Varvarovka.

The town of Anapa is the largest Local Community and is also the nearest large urban settlement, approximately 10 km to the north of the landfall section of the Project. With the exception of Anapa, the surrounding area is largely rural and includes a number of small- to medium-sized communities near the landfall section of the Project. Of the remaining Local Communities, Varvarovka is the closest to the landfall section; it is located approximately 2 km northwest of the Project Area. All of the Local Communities are situated within the ART municipal district.

Further information on the Local Communities is in Chapter 14 Socio-Economics.

Vulnerable Groups

Stakeholder identification and engagement also seeks to identify any potentially vulnerable or disadvantaged individuals and groups in local communities. Vulnerable groups are those who may be differently or disproportionately affected by the Project, or whose situation may mean that special care is needed to engage them in consultation and disclosure activities (e.g. in terms of language, literacy, technology, etc.).

Using guidance provided in IFC PS 1 and in consultation with two social protection bodies in Supsekh and Gai Kodzor, and the Anapa Resort Town (ART) Municipal District administration, the following potentially disadvantaged or vulnerable groups have been identified in the Local Communities:

- Children;
- Elderly;
• Disabled or chronically ill;
• Low-income households (with incomes below the subsistence level);
• Migrants workers; and
• Commercial sex workers.

Where relevant, differential impacts on these groups have been considered in the relevant impact assessment chapters of this ESIA Report (e.g. Chapter 9 Air Quality; Chapter 14 Socio-Economics; Chapter 15 Community Health, Safety and Security).

South Stream Transport has considered the needs of all potentially interested stakeholders, including those for whom special care in consultation may be needed, throughout the stakeholder engagement process. Efforts have been made to disclose information in a variety of ways so as to be accessible to all groups, regardless of socio-economic or other status. For example, printed copies of reports have been provided in central community locations, in addition to on the internet; announcements have been made in local and national newspapers, and through posters in local shops, offices, bus stops, and other community locations; information has been hand-delivered to schools and pensioner groups; and open meetings have been held in the Local Communities. All documents have been provided in Russian.

6.3.3 Receiving Feedback from Stakeholders

South Stream Transport is committed to maintaining an open and respectful dialogue with all stakeholders, supported by the activities and principles of the SEP. Throughout the life of the Project, stakeholders have access to various means and opportunities to submit feedback to South Stream Transport. Feedback may include:

• Questions;
• Comments;
• Concerns;
• Requests;
• Complaints or grievances; and
• Suggestions and recommendations.

Stakeholder engagement activities comprise both ‘active’ and ‘receptive’ consultation. Active engagement includes meetings, public hearings and structured comment periods to support report disclosure where South Stream Transport is actively soliciting feedback about the Project. Complementary to these active periods of disclosure and consultation, South Stream Transport is always receptive to feedback, whereby stakeholders may contact the Project at any time (e.g. by email, post, telephone, or in person) to provide their views and ask questions. Feedback may be submitted by any individual or group (e.g. companies, organisations, societies, collectives), either verbally or in writing.

All input received from stakeholders is managed through the Stakeholder and Consultation Database (SCD; Section 6.3.4); through this platform, South Stream Transport centrally stores, analyses and manages comments from stakeholders. If a grievance is communicated to South
Stream Transport, through any means, the communication is documented in the SCD, and the Grievance Procedure (Section 6.3.5) is initiated.

### 6.3.4 Stakeholder and Consultation Database

South Stream Transport’s Stakeholder and Consultation Database (SCD) has been developed to ensure that stakeholder communications are documented, feedback is recorded and resulting actions are tracked and addressed. The SCD also provides a history of engagement with a particular stakeholder, thus helping South Stream Transport build meaningful relationships with stakeholders by understanding their concerns and past involvement with the Project.

The SCD is used to record and analyse feedback received from stakeholders and, in turn, this analysis informs the development of Project design, the identification and management of impacts and the development of the Environmental and Social Management System (Chapter 22 Environmental and Social Management). Throughout the life of the Project, the SCD will be a valuable tool to coordinate information about stakeholders and stakeholder concerns in relation to the Project.

### 6.3.5 Grievance Procedure

A grievance is a complaint (i.e. an expression of dissatisfaction) stemming from an incident or impact (real or perceived) related to South Stream Transport’s business activities. Complaints may stem from commonly occurring and relatively minor problems, or more serious one-off events, or entrenched or repeated problems that may lead to resentment, discontent or unrest.

A Grievance Procedure is the process by which a grievance is received, recorded and managed so that it can be tracked from its original submission through to a resolution. An effective Grievance Procedure is an important aspect of stakeholder engagement, and is a core component of the approach to stakeholder engagement outlined in the standards and guidelines for financing (Section 6.2). The process must be fair, accessible, transparent and properly documented.

The Grievance Procedure for the Project will guide the management of grievances throughout the Project lifecycle, from before the start of construction, throughout the operational life, and into decommissioning. The Grievance Procedure describes the process by which a grievance is documented, investigated, and resolved in coordination with the affected stakeholders.

It will be implemented by South Stream Transport in partnership with its contractors and will ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way.

As the South Stream Offshore Pipeline is part of the overall South Stream Pipeline System it must also interface with the upstream and downstream components of the System. The HSSE Integrated Management System (HSSE-IMS) contains a dedicated Interface Procedure to manage the HSSE interface with Gazprom Invest (GPI) and South Stream Bulgaria AD (SSB). This includes coordination, cooperation and agreement on stakeholder engagement and the grievance procedure.
The Grievance Procedure interfaces with the SCD and the general receipt and management of feedback from stakeholders. All communications with stakeholders will be respectfully considered by South Stream Transport, and responses will be provided where appropriate. Where a potential grievance is identified, the Grievance Procedure will be implemented in addition to standard stakeholder engagement procedures, although the two processes will be closely integrated.

Further information regarding the implementation of the Grievance Procedure is provided in the SEP.

6.4 Stakeholder Engagement by Project Phase

Stakeholder engagement activities are an integral part of the Project lifecycle: from the initial notification when the Project is proposed, to the scoping of potential impacts, the EIA and ESIA studies, and throughout the Construction and Pre-commissioning, Operational and Decommissioning Phases of the Project.

The different phases of the Project each require stakeholder engagement that is tailored in terms of its objectives and intensity, as well as the forms of engagement used. In Russia, stakeholder engagement for the Project commenced in the Feasibility Phase (Phase 1) in 2010 with the official Project Notification and preliminary EIA. The Project is currently in the Development Phase, which includes the EIA and ESIA studies. Details of completed and planned engagement activities for the Project are provided in Figure 6.2.

Although the guidelines for stakeholder engagement under the EIA and ESIA processes differ the Project has aligned these processes were possible. As such, the activities for both processes are described in this section.

A discussion of stakeholder feedback obtained through these activities—including a short summary of the comments, suggestions and concerns raised by stakeholders to date, and how they have been addressed as part of the ESIA process—is provided in Section 6.5.

  • Continued implementation of the Grievance Procedure | |
| Decommissioning       | Decommissioning Activities  
  • Inform stakeholders about planned decommissioning activities and schedule  
  • Continued implementation of the Grievance Procedure | |
6.4.1 Phase 1: Feasibility Phase

With respect to stakeholder engagement, the Feasibility Phase included the official announcement and notification of the Project to the regulators and other stakeholders as part of the national EIA process. In April 2010, prior to establishment of South Stream Transport, Gazprom, the original proponent of the Project, submitted the Declaration of Intent for the Project to the Krasnodar Krai Administration.

Feasibility studies were undertaken, including the Preliminary EIA\(^3\) for the Project, which provided a description of the Project and an initial identification of potential impacts. Announcements were placed in national\(^4\), regional\(^5\) and local\(^6\) press inviting interested parties to participate in discussions on the Preliminary EIA.

Two public meetings were held – in Gelendzhik on 17 May 2010 and in Anapa on 18 May 2010 – as part of the consultation process. The Preliminary EIA was submitted for State Review, and approved\(^7\) on 24 September 2010. Further public discussions were held in January 2011 in Anapa and Gelendzhik to discuss the Terms of Reference (ToR) for the Environmental Impact Study (EIS) and proposed business and other activities in the Gelendzhik Resort Town Municipal District, which were subject to environmental evaluation. These four meetings were attended by Commission Members, Gazprom, representatives from the administrations, public organisations, businesses, environmental organisations and the General Public (including residents from Local Communities and tourists).

South Stream Transport was established in October 2011 and became the proponent of the South Stream Offshore Pipeline\(^8\). South Stream Transport met with the Krasnodar Krai Administration, ART Municipal District Administration, Gai Kodzor Rural District Administration and Supsekh Rural District Administration in June and August 2012 to present further information about the Project and discuss how these authorities wished to engage with the Project and with the EIA and ESIA processes. Feedback received at these meetings is described in Section 6.5: Stakeholder Comments and Suggestions.

\(^7\) During their review, SEER took into account the findings of the Federal Fisheries Agency No. 4272-VB/U02 dated 19 July 2010 on approval of "Feasibility Study for the Offshore Section of Gas Pipeline 'South Stream', and a letter of ART Municipal District Administration No.103/206-156 dated 27 May 2010.
\(^8\) South Stream Transport A.G. (SSTTAG) was established in Switzerland in October 2011, and was the project proponent prior to the establishment of South Stream Transport B.V. in the Netherlands in November 2012.
6.4.2 Phase 2: Development Phase

6.4.2.1 Overview

At the time of writing, the Project is currently in the Development Phase, which includes both the development of engineering and design, as well as the ESIA and related studies. The Development Phase is an important period of stakeholder engagement as it provides an initial introduction with many stakeholders, and can provide valuable feedback to inform Project design, baseline studies, impact assessment, and mitigation and management planning. Stakeholder engagement during this Phase aims to:

- Source and validate relevant environmental, socio-economic and cultural heritage data;
- Further understand the views and concerns of stakeholders about the Project, its impacts and possible mitigation, management and monitoring measures; and
- Discuss the outcomes of the EIA and ESIA processes, including anticipated impacts and their significance, and mitigation and management measures.

In terms of stakeholder engagement, the Development Phase includes three main activities:

- The Scoping process included separate periods of disclosure and consultation related to the Terms of Reference (as the basis for the national EIA Report) and the Scoping Report (as the basis for the ESIA Report). These activities are described in Section 6.4.2.2. Other meetings held as part of the ESIA consultation meetings are presented in Section 6.4.2.3 and engagement with the media is summarised in Section 6.4.2.4;
- The EIA Report process included disclosure and consultation related to the draft EIA Report. These activities are described in Section 6.4.2.5; and
- The ESIA Report process includes disclosure and consultation related to this Report, in accordance with the standards and guidelines for financing. Planned activities are described in Section 6.4.2.6.

Additional stakeholder engagement activities related to the baseline data collection are described in Section 6.4.2.3.

6.4.2.2 Completed Activities – Scoping Process

During the scoping process, South Stream Transport sought to provide stakeholders with clear information about the Project and its potential impacts and to allow them to provide feedback on the scope of, and approach to, the EIA and ESIA, including the key issues to be addressed as part of both processes. Stakeholders also had an opportunity to give their views about plans for future engagement activities, including any preferences for methods, materials and schedule. The engagement process during the Development Phase also served to source and validate relevant environmental, socio-economic and cultural heritage data and to understand the views and concerns of stakeholders about the Project, its impacts and possible mitigation, management and monitoring measures. Feedback from these activities informed the EIA and ESIA process and Project design.
Consultation on the Terms of Reference for the EIA Report

Based on the outcomes of the Preliminary EIA (completed by Gazprom as the previous proponent), South Stream Transport prepared a Draft ToR for the national Proekt EIA; this document outlined the proposed scope and content of the forthcoming EIA Report. An announcement marking the start of the disclosure and consultation period was published in national, regional and local newspapers on 31 July 2012. This 30-day consultation period ran from 1 to 31 August 2012, during which time stakeholders had the opportunity to read and comment on the Draft ToR document.

Printed and bound copies of the Draft ToR document, along with brochures describing the Project and the ESIA process, were made available in the following locations:

- Community Centre in Varvarovka;
- Community Centre in Gai Kodzor; and
- Department of Architecture and Town Planning in Anapa.

Comment forms and comment boxes were provided for stakeholders to submit their comments; comment boxes were securely locked so that only South Stream Transport staff could access the comments. Stakeholders were also able to access the Draft ToR on the South Stream Transport website and submit comments by post, email, or by telephone.

Comments received during this consultation period were considered in the development of the EIA Report, and where relevant also informed the development of the ESIA process (including Scoping Report and ESIA Report).

Disclosure of the Scoping Report for the ESIA

The Scoping Report, including a Non-Technical Summary (NTS), was disclosed on 22 November 2013 and the consultation period ran until 28 January 2013. To ensure the Scoping Report was accessible to all stakeholder groups, efforts were made to disclose information in a variety of ways. All stakeholders had the opportunity to submit comments on the Scoping Report and to attend meetings to discuss the Project and the Scoping Report. Disclosure of the Scoping Report included:

- Publication of the Scoping Report and NTS on the South Stream Transport website on 22 November 2013 along with a Press Release explaining the Project and Report disclosure;

---

5 In newspaper Rossiiskaya Gazeta, 31st July 2012.
6 In newspaper Kubanskie Novosti, 31st July 2012.
7 In newspaper Anapskoye Chernomorye, 31st July 2012.
8 South Stream Transport B.V. was established on 14 November 2012 and became the new proponent of the South Stream Offshore Pipeline.
• Direct distribution of printed and bound copies of Scoping Report and NTS to identified stakeholders by hand, post and email (See Table 6.2);

• Installation of ‘comment boxes’ in Community Centre in Varvarovka (Figure 6.3); the Community Centre in Gai Kodzor; and the Department of Architecture and Town Planning in Anapa on 20 November 2012 until 28 January 2013 where the public were invited to review a printed copy of the Scoping Report and NTS and submit comments by using the secure box;

• Publication of a Public Announcement in local newspaper Anapskoe Chernomorye on 8 December 2012 including details of the Project, the Scoping Report and planned community meetings (Figure 6.4), as well as the locations of the comment boxes and printed copies of the Scoping Report and NTS; and

• Posters announcing the three open-house style community meetings in the Local Communities and were displayed in public spaces including local shops, offices, bus stops, on information boards and in other community locations from 29 November 2012 until the meetings were concluded.

Information was also hand-delivered to school representatives, representatives of health care facilities, local NGOs, entrepreneurs, shop owners, cafes/restaurants, representatives of religious institutions and representatives of community centres.

**Figure 6.3 Comment Box in Varvarovka**
The Scoping Report was made publicly available for review and comment for a period of almost two months, which included the normal 30 day disclosure period and an additional month, as some stakeholders were expected to be on holiday over the Christmas and New Year holiday period. Stakeholders submitted comments by post or email, or in person. All comments received (listed in Appendix 6.1 and summarised in Section 6.5) were documented and taken into consideration in this ESIA Report.

Figure 6.4 Scoping Report Public Announcement in Anapskoe
Chapter 6 Stakeholder Engagement

The disclosure activities related to the Scoping Report are summarised in Table 6.2 below. All documents were disclosed in Russian, and the website included both Russian and English versions.

† Engagement with the media at the time of the disclosure of the Scoping Report is covered in Section 6.4.2.3.

*Copies of the Scoping Report made available in the Varvarovka Community Centre, the Gai Kodzor Community Centre and the Department of Architecture and Town Planning, town of Anapa.

Scoping Consultation Meetings

In association with the disclosure of the Scoping Report and consultation with the competent authorities (described above), additional scoping consultation meetings were held in December 2012. Meetings included roundtable meetings with specific stakeholder groups, and open-house community meetings in Varvarovka, Gai Kodzor, and Supsekh for anyone interested in the Project. These meetings are summarised in Table 6.3 and the locations of the scoping consultation meetings are shown in Figure 6.5.

The open-house style community meetings were held in the communities that are closest to the Project Area, where interest in the Project was also highest. Initial plans included two community meetings: in Varvarovka (including representatives from Supsekh and Sukko, which are part of the same rural district) and in Gai Kodzor, which is part of a different rural district. However, after discussion with local representatives it was decided that holding a separate meeting in Supsekh would be more appropriate for Supsekh residents; as such, South Stream Transport arranged for a third community meeting, in Supsekh. In order to ensure the open-house community meetings were accessible and locally relevant, these events were held in community centres in Varvarovka and Gai Kodzor, and at a school in Supsekh. The roundtable meetings were held in centrally located hotel conference rooms in Moscow and Anapa.

</tr>
</tbody>
</table>

Invitation letters were sent to stakeholders in advance of the meetings, accompanied by the Scoping Report and NTS, by email, post and by hand. The community meetings were also advertised in the local press in early December 2012. In addition, posters advertising each of the three community meetings were displayed in the Local Communities between 29 November and 10 December 2012.

More than 100 people attended the three meetings that were held in the Local Communities. The community meetings were open to all members of the public and were held in the early evening (after the end of the working day) so as to maximise the opportunities for both working and non-working people to participate. For the roundtable meetings, local, regional and national NGOs were invited to meetings to discuss the Project and the Scoping Report. Local and regional NGOs were invited to a meeting in the town of Anapa, while national NGOs were invited to a meeting in Moscow. All organisations invited were given the opportunity to present their views in writing if they preferred. A meeting was also planned in Anapa with marine space users and local businesses. Six organisations that are marine space users and four local

---

14 In newspaper Anapskoye Chernomorye on 8 December 2012.
15 Written feedback was received from a number of Russian NGOs in February 2013.
businesses confirmed their interest in these meetings but no representatives of these groups attended.

The community and roundtable meetings, which took place approximately three weeks after the Scoping Report was disclosed, were organised to facilitate the exchange of information and opinions. At the meetings, representatives of South Stream Transport presented information about the Project, the Scoping Report and the ESIA process. As shown in Figure 6.6, meeting participants were invited to provide comments and suggestions, both in the meeting itself and afterwards; written comments could be submitted at the meeting, or by post or email. Participants also had the opportunity to speak individually with representatives of South Stream Transport after the question and answer sessions were finished.

Visual and printed materials were made available to support the presentations and discussion, including additional copies of the Scoping Report and the NTS, as well as leaflets describing the Project and the ESIA process. Figure 6.6 illustrates the general presentation format of the meetings for both the community and roundtable meetings. The meetings were conducted in Russian, with translation between Russian and English as necessary.

Details of all discussions were documented by South Stream Transport so that they could inform the ESIA and on-going Project planning and design. The issues raised in these discussions are described in Section 6.5.2.2 and Table A6.1.2 shows how they have been considered as part of the ESIA process.

Figure 6.5
Since the disclosure of the Scoping Report, Rassvet has also been defined as a Local Community (section 6.3.2) due to confirmation of the construction traffic access route which will pass through Rassvet (see Chapter 15 Community Health, Safety and Security). Although specific engagement was not undertaken in the community of Rassvet for the Scoping Report disclosure and consultation meetings, it will occur for consultation activities associated with the disclosure of the ESIA Report (refer to Section 6.4.2.4 for planned activities).

6.4.2.3 Completed Activities – Other Meetings

In addition to the scoping consultation meetings, meetings have also been held with other stakeholders to engage them with the Project in relation to their activities, provide updates on the Project, discuss technical issues and gather baseline data and information to input into the EIA and ESIA reports. These meetings, which generated comments and feedback of relevance to this ESIA Report, included:

1. Meetings with Krasnodar Krai Regional Administration, ART Municipal District Administration, Supsekh Rural District Administration and Gai Kodzor Rural District Administration, in 2012 and 2013;

2. Meetings with fishing organisations in April and October 2013, and with the development company Fond Yug, the Kavkaz Winery and the Shingari Holiday Complex in October 2013. Meetings were also held with a horse riding company in Varvarovka and an environmental specialist in Anapa; and

3. Meetings with ART Municipal District Administration, Supsekh Rural District Administration and Gai Kodzor Rural District Administration, and Rassvet School, in February 2014.

The purpose of the meetings with the regional and district administrations was primarily to engage and discuss with them the Project and their involvement in the EIA and ESIA processes, and gather information and data where necessary. Representatives of the administrations in the Anapa area were also invited to comment on key EIA and ESIA documents (i.e. ToR, SR and EIA) and given the opportunity to meet with representatives of South Stream Transport to discuss these documents, as well as to attend the community meetings. Comments raised during these meetings are included in Section 6.5.2.1 and Table A6.1.2 in Appendix 6.2.
The purpose of the meetings with the other stakeholders was to discuss the Project and how it relates to their activities, and to gather socio-economic data and information for the EIA and ESIA reports. Comments raised during these meetings are included in Section 6.5.2.3 and Table A6.1.2 of Appendix 6.2.

6.4.2.4 Engagement with Media

The Russian media have been engaged with the Project at key milestones in the ESIA stakeholder engagement process including:

- Distribution of press releases around major milestones including, but not limited to, the disclosure of reports;
- Newspaper advertisements used to communicate with stakeholders disclosure of reports and information about ESIA stakeholder meetings;
- Press events organised around the disclosure of the Scoping and Draft EIA Reports to provide information to journalists and media stakeholders to give them an opportunity to engage with representatives from South Stream Transport and ask questions; and
- Attendance at the EIA Public Hearing.

6.4.2.5 Completed Activities – National EIA Report

Under the national EIA process, the Draft EIA Report was disclosed for comment on 29 April 2013. An announcement marking the start of the Draft EIA disclosure and consultation period was published in national, regional and local newspapers in April 2013.

Printed and bound copies of the Draft EIA Report were made available in the same locations as for the Scoping Report:

- Community Centre in Varvarovka;
- Community Centre in Gai Kodzor; and
- Department of Architecture and Town Planning in the town of Anapa.

Comment stations (including comment forms and secure comment boxes) were provided where stakeholders could review the report and submit their comments. Stakeholders were also able to submit comments by post, by email or by telephone.

A Public Hearing was held on 31 May 2013, in the town of Anapa; the details were announced in the local media. At the hearing, representatives of South Stream Transport presented information about the Project, the Draft EIA Report and the EIA process. Participants were invited to provide comments and suggestions. Participants also had the opportunity to speak individually with representatives of South Stream Transport after the question and answer

18 In newspaper Anapskoye Chernomorye, 27th April 2013.
sessions were finished. Visual materials were made available to support the presentations and discussion. The hearing was conducted in Russian, with translation between Russian and English as necessary.

An official record of the hearing was prepared by the ART Municipal District and signed by the presenting team and the ART administration representatives. This record included the comments received via the secure comment boxes. The main issues raised are included in the comment summary in Section 6.5.2.2 and Table A6.1.2 in Appendix 6.2.

**6.4.2.6 Planned Activities – ESIA Disclosure and Consultation**

The consultation programme for this draft ESIA Report has considered the combined outcomes of both EIA and ESIA engagement activities to date. The objectives of the draft ESIA Report engagement programme are presented below, whilst the SEP contains more detailed information on the engagement programme. The SEP is available on the South Stream website, and copies will also be made available during the ESIA disclosure period.

The focus of further engagement activities during the ESIA process is to ensure that Local Communities and other key stakeholders are provided with the opportunity to:

- Access clear and appropriate (i.e. non-technical, local language) information on the Project and its potential impacts;
- Provide feedback on the content of the ESIA including the assessment of impacts, and the proposed mitigation, management and monitoring measures; and
- Provide input regarding plans for future engagement activities, including preferences for methods, materials and schedule.

Whereas the legal provisions for public consultation and disclosure for the national EIA process end with Public Hearings on the Draft EIA, for the international ESIA process, engagement goes beyond ESIA disclosure and consultation and continues during the Construction and Pre-Commissioning, Operational and Decommissioning phases of the Project. This reflects the recognition that relationships with stakeholders are on-going throughout the life of a project and on-going engagement will ensure that stakeholders are consulted about activities that may affect them at any stage of a project.

This draft ESIA Report has been publicly disclosed along with a non-technical summary of the Report. These documents are available online at [http://www.south-stream-offshore.com](http://www.south-stream-offshore.com), along with information about upcoming stakeholder engagement activities and the ways in which stakeholders can provide comments on the Project and the ESIA. Announcements have been made through local and national media. Documents and announcements have also been provided directly to the key stakeholders identified to date and are available in the office of the Project Community Liaison Officer.

Alternatively, interested stakeholders can contact South Stream Transport (Table 6.5), either via the Project’s Information Centre in Krasnodar or via the Amsterdam Head Office, to request a copy of the ESIA Report, non-technical summary, or other information. Stakeholders can also provide questions and comments via these communication channels.

Stakeholders have the opportunity to comment in writing and to attend community meetings to discuss the Project, the draft ESIA Report and related documentation. The community meetings will allow stakeholders to express their views and ideas about the Project and the ESIA to representatives of South Stream Transport and the ESIA consultants, as well as to provide additional information or suggestions to assist the ESIA process and Project planning. Roundtable meetings with groups of related stakeholders are also planned; additional meetings with specific stakeholders may also be organised, as appropriate.

Comments received on the draft ESIA Report will be taken into consideration in the preparation of the final ESIA Report. The final ESIA Report will be disclosed on the South Stream Transport website and will inform later phases of the Project.

### 6.4.3 Construction and Pre-Commissioning, Operational, and Decommissioning Phases

Stakeholder engagement will continue over the life of the Project throughout the Construction and Pre-commissioning, Operational and Decommissioning Phases. With an operational life of 50 years, South Stream Transport is committed to maintaining relationships and communications with stakeholders over this time.

During the Construction and Pre-Commissioning Phase, and in subsequent phases, the emphasis of engagement shifts to focus on consultation and disclosure about activities that are on-going or about to take place, and receiving feedback from stakeholders about on-going activities.

Engagement activities will include published announcements and updates about the progress of the Project. The Grievance Procedure will also be a key element of the Construction and Pre-Commissioning Phase and later phases of the Project. Plans for on-going stakeholder engagement are described in more detail in the SEP, which will be updated as the Project progresses. Engagement activities will be adjusted to reflect evolving stakeholder preferences and concerns over the life of the Project.
6.5 Stakeholder Comments and Suggestions

6.5.1 Overview

This section summarises the general comments and suggestions received from stakeholders during the EIA and ESIA consultation processes to date, how these comments have been considered and responded to in this ESIA Report and, in some instances, how the response from the Project has been communicated to stakeholders in advance of the ESIA Report disclosure process. The feedback received has been divided into that from:

1. National, regional and local authorities i.e. Russian national, regional and local government, primarily gathered during meetings related to the EIA process (summarised in Section 6.5.2); and

2. The public and other non-governmental stakeholders (e.g. residents of Local Communities, fisheries and marine area users, NGOs, Inter-governmental organisations, fisheries unions and cooperatives, academic and scientific organisations) engaged primarily through the ESIA process (summarised in Section 6.5.3).

The following sections present summaries of how stakeholder feedback has been considered and responded to by the Project, through the EIA and ESIA processes. As the EIA and ESIA processes have run in parallel, the disclosure of the EIA documentation, and the EIA public hearing, has served to detail the Project response to some of the issues raised by stakeholders during the scoping consultations. Similarly the feedback from stakeholders on the EIA documentation has further informed the ESIA. A full list of the comments received is provided in Appendix 6.1 of this chapter. A list of all stakeholder engagement activities to date is provided in Appendix 6.2.

6.5.2 National, Regional and Local Authorities

During the Development Phase and since June 2012, a number of meetings were held with the regional, municipal and rural district authorities across the Local Communities of the Town of Anapa, Supsekh, Varvarovka, Sukko, Gai Kodzor and Rassvet, to discuss the Project and gather feedback and information from the Local Communities, for data collection and to discuss key issues and potential impacts of the Project.

Table 6.5 summarises the main comments and issues raised by authorities and related stakeholders during the Project’s Scoping Stage engagement activities, and provides a description of how South Stream Transport has considered and responded to these comments through the EIA and ESIA processes.

---

19 Only meetings of relevance to the ESIA process included in this chapter.

20 Note that the responses provided are intended to be technically correct at the time of writing. Due to the evolution of Project planning, design and schedule, this may not be the same as the response that was provided at the time the question or concern was raised.
### Table 6.5 Comments Received from National, Regional and Local Authorities

<table>

<tbody>
<tr>
<td><strong>Traffic</strong></td>
<td>A bypass road was constructed to the east and south of Gai Kodzor in early 2013 by Gazprom Invest for vehicles traveling to the site of the Russkaya Compressor Station from the M25. To avoid damage to the main road and impacts on the community in Gai Kodzor, construction traffic related to the Project will also be diverted around Gai Kodzor using this bypass road. Existing damage to the road through Gai Kodzor was repaired in early 2013. Subsequent engagement with the Gai Kodzor local administration (early 2014) has confirmed that the traffic and road quality issues in Gai Kodzor were resolved with the construction of the bypass road and the completion of the repairs. The town of Rassvet has subsequently also been identified as one that will be impacted by Project construction traffic. Site visits and specific consultation with the local authority were undertaken in relation to this issue in early 2014 and mitigation measures proposed (see Chapter 15 Community Health, Safety and Security and Appendix 20.1 Environmental and Social Impacts of Associated Facilities: Russkaya Compressor Station). In addition, the Project has committed to the construction of a bypass road to divert traffic from the centre of Varvarovka thereby avoiding the main traffic related impacts during construction.</td>
</tr>
<tr>
<td>Will local communities benefit from the new Project gas supply?</td>
<td>South Stream Transport is a gas transport rather than a gas delivery company and is not involved in the provision of gas to the local population. At the Scoping meetings where this issue was raised, the representatives of South Stream Transport stated that although the supply of gas to local communities is outside the scope of the Project, the questions from the community would be passed to Gazprom. South Stream Transport met with representatives of Gazprom in May 2013 and discussed the issue of gas supply. Gazprom stated that a co-operation agreement was approved by the Governor of the Krasnodar Region and the Chairman of the Management Committee of Gazprom that covered gas supply and gasification of the south-western area of the Krasnodar Krai, including the Anapa region.</td>

<tbody>
<tr>
<td>Will the Project be making any financial contributions to development in the rural districts?</td>
<td>South Stream Transport has a Community Investment Programme. This will guide the company’s activities in the Local Communities beyond the direct scope of the Project, and may include support for local development initiatives. Through the Community Investment Programme, South Stream Transport will work with local stakeholders to identify suitable community investment opportunities.</td>
</tr>
</tbody>
</table>

### Noise and Vibration

| Questions related to Project-generated noise and how it will be managed. | South Stream Transport conducted a noise impact assessment for the construction and operation of the Project. Due to design changes (the construction of a bypass road to divert construction traffic from the centre of the community of Varvarovka) and the use of the compressors during the pre-commissioning activities, the noise assessment was revised in early 2014 and found that there will be moderate level, short term and temporary noise impacts in some areas of Varvarovka during construction. The mitigation, management and monitoring of noise impacts is detailed in Chapter 10 Noise and Vibration and in Chapter 15 Community Health, Safety and Security. |

### Health and Safety

| Questions related to safety, particularly in the event of a gas explosion. | The Project has developed specific design criteria which comply with Russian legislation and European and international pipeline industry standards to minimise the risk associated with gas leakages (and subsequent fires and explosions) and therefore protect members of the public in surrounding areas, the operational workforce and the environment. Information on the Project design and safety issues was contained in the draft EIA Report disclosed for public comment in the second quarter of 2013.

The risk of a gas leak or explosion is very small. In any event, the Project will include the preparation of emergency response plans to ensure that emergency response procedures are implemented and understood. Further information can be found in Chapter 19 Unplanned Events and Chapter 22 Environmental and Social Management. |

6.5.3 Public and Other Non-Governmental Stakeholders

This section summarises the feedback received from the public and other stakeholders (including NGOs, local business, administrations, marine area users, etc.) during the:

1. EIA Terms of Reference disclosure and consultation period;
2. Scoping Report disclosure and consultation period, including community meetings and roundtable meetings;
3. EIA Report disclosure and consultation period, including the EIA Public Hearing; and
4. Meetings and other communications with stakeholders outside of official consultation periods, including data collection meetings.

Feedback from the public and other stakeholders during the Scoping Report disclosure and consultation period was received through a series of scoping consultation meetings (including roundtable and community meetings) and in writing. Feedback received during the EIA Report disclosure and consultation period has also been considered by South Stream Transport in this ESIA Report.

Stakeholders had the opportunity to provide comments and suggestions outside of these formal periods, including at meetings with South Stream Transport, or by contacting South Stream Transport or its consultants by telephone, email or post or in person. The Project organised various meetings with stakeholders (referred to in Section 6.4.2.2) to ensure they were engaged with the Project and to gather baseline data and information, to input into the EIA and ESIA reports.

The most common topics raised included the following:

- Questions regarding Gazprom and gas supply to the Local Communities;
- Potential impact of the Project on the terrestrial environment (including the coastline and onshore valuable habitat areas) and the marine environment (including marine ecology and any restrictions to fishing and shipping activities) and questions raised regarding mitigation measures implemented by the Project to manage impacts;
- Questions about safety of the Project, including potential emergency situations and emergency response measures;
- Questions about how the Local Communities will benefit from the Project and how the Project will manage potential impacts on the coastline and the tourism industry;
- Questions about how the Project is engaging with its stakeholders to ensure public opinion is considered;
- Potential impact of increased project-related traffic on the existing road network and Local Communities in relation to noise and vibration;
- Questions about the routing of the Pipeline and whether alternative options were considered; and
- Questions about the EIA and ESIA processes.
This stakeholder feedback is summarised in Table 6.6, which contains a summary of the main comments, issues and questions raised by stakeholders and how these have been considered and responded to by the Project.

**Table 6.6 Summary of Public and Other Stakeholder Comments**

<tr>
<td><strong>Gazprom, Gas Supply and Russkaya Compressor Station</strong></td>
<td></td>
</tr>
<tr>
<td>Gas supply for local communities such as Varvarovka and Sukko.</td>
<td>South Stream Transport is a gas transport rather than a gas delivery company and is not involved in the provision of gas to the local population. At the Scoping meetings where this issue was raised, the representatives of South Stream Transport stated that although the supply of gas to local communities is outside the scope of the Project, the questions from the community would be passed to Gazprom. South Stream Transport met with representatives of Gazprom in May 2013 and discussed the issue of gas supply. Gazprom stated that a co-operation agreement was approved by the Governor of the Krasnodar Region and the Chairman of the Management Committee of Gazprom that covered gas supply and gasification of the south-western area of the Krasnodar Krai, including the Anapa region.</td>
</tr>
<tr>
<td>Issues related to the construction of the Russkaya compressor station, including: protection of the environment and restoration of the landscape to its original state following Project activities, and concerns about noise, traffic and road quality.</td>
<td>The Russkaya Compressor Station is not part of the Project, and will be designed and installed as part of a separate project known as “Expansion of the UGS (United Gas Supply System) to provide gas to South Stream Pipeline” which is being constructed by Gazprom Invest. However, the potential for cumulative effects of the Project with the Russkaya Compressor Station has been assessed in Chapter 20 Cumulative Impact Assessment and details of the impacts of the Russkaya CS as outlined in the EIA for the development can be found in Appendix 20.1 Environmental Impacts of Associated Facilities: Russkaya Compressor Station. South Stream Transport is engaging with Gazprom Invest with the aim of aligning Gazprom Invest’s ecological mitigation strategy and mitigation measures as related to the Russkaya CS development with those of the Project. Of particular importance is the avoidance of impacts through the sensitive timings of works (including the herpetiles hibernation period), implementation of herpetile fencing and a programme of translocation, and adherence to good industry practice as well as to develop measures that would enhance biodiversity management within the wider area. In addition, South Stream Transport is liaising with Gazprom Invest with the aim of developing aligned and coordinated traffic management plans. Discussions are on-going at the time of writing.</td>
</tr>

</table>

*Continued...*
Environmental Protection (Onshore)

Potential adverse impacts on the natural environment, including the marine environment, the coastline, onshore valuable habitat areas (e.g. the mountain area of the Kilberov Canyon, Sukko Beach), juniper trees and local wildlife.

Potential impacts on habitats and ecology have been assessed in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology. These chapters have considered potential impacts on a range of ecology receptors, including designated sites, natural habitats and protected species of plants and animals. The key impacts relate to habitat loss and fragmentation, severance, habitat degradation, direct mortality and injury to species. These chapters also describe the mitigation, management and monitoring measures that will be implemented in order to avoid and/or minimise these impacts.

The landfall section of the Project contains a short section that runs through some areas that serve as a habitat for the protected Nikolski’s Tortoise and for protected Juniper along with some other protected species of flora and fauna. The Project will implement special mitigation measures to protect these species during construction of the Project, including the relocation of these species from the construction site to alternative areas.

The relocation of Juniperus trees took place in April 2014 with trees being relocated from Varvarovka to Anapa. The relocation process was supervised by Rosprirodnadzor from the Ministry of Natural Resources and Environment to ensure the process complied with the legal permit conditions. In addition, the Project has committed to further reinstate parts of the sea cliff near Varvarovka that were impacted by geotechnical surveys during the Feasibility Phase, including replanting of juniper trees (see Chapter 11 Terrestrial Ecology and Appendix 11.2 Outline Cliff Reinstatement Plan of this ESIA Report).

Before the start of construction activities, South Stream Transport will safely move the tortoises to suitable areas nearby, in accordance with the relevant legislation and when the tortoises are not hibernating. The construction area will also be fenced and tunnels will be installed, to avoid entry of the tortoises into the construction site.
<table>
<thead>
<tr>
<th>Comments</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Project should follow the relevant environmental protection laws and propose appropriate mitigation measures.</td>
<td>In addition to the relevant Russian laws and regulations, the Project is following the standards and guidelines of financing organisations (see Chapter 2 Policy, Regulatory and Administrative Framework). The relevant national laws and regulations in relation to the environment were addressed in the EIA for the Project which was disclosed in the second quarter of 2013 (see Section 6.4.2.4). Members of the public were able to attend the open public hearing on the EIA held in the town of Anapa and to ask questions and make comments on the EIA process and content, including proposed mitigation measures. The EIA was approved by the Russian authorities in late 2013 and early 2014. A newspaper announcement was published in the local press in May 2014 in order to inform stakeholders that the regulatory process had been followed and completed in relation to the EIA. In addition, for each topic in the ESIA, where impacts have been identified, mitigation measures have been proposed and these are detailed under each topic chapter of this ESIA Report which will be publicly disclosed in mid-2014. Some of the proposed mitigation measures have been discussed directly with relevant stakeholders (for example the Utrish Nature Reserve and the Moscow Academy of Sciences), such as the relocation of protected species.</td>
</tr>
<tr>
<td>Controls should be put in place to minimise harmful impacts e.g. minimising Project generated waste and other discharges to the environment.</td>
<td>An assessment of waste-related impacts and management measures is provided in Chapter 18 Waste Management. Project staff have visited potential waste disposal facilities and discussed the issue of waste management with the local Anapa administration during 2013, in advance of agreeing the final facilities with the construction contractor. An Environmental and Social Management Plan will include measures to minimise waste production and encourage re-use and recycling of materials where possible. The Project will use only existing licensed facilities for waste disposal and all vessel discharges and waste will be compliant with Marine Pollution (MARPOL) Convention, Bucharest Convention and national regulations.</td>
</tr>
<tr>
<td>The Project should not impact on ecosystems or disturb the ecological balance.</td>
<td>An assessment of the Project’s impact on ecosystems has been undertaken to identify likely impacts and measures to reduce the impact or mitigate against any adverse impacts. Potential ecological impacts and management measures are described in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology. Additionally, potential impacts (and mitigation) related to potential impacts on the value, function and services of ecosystems on which local communities and/or the Project depend, are described in Chapter 17 Ecosystems Services.</td>
</tr>
</tbody>
</table>

Continued...
How will the landscape be rehabilitated and restored to its original state after the Project activities?

A Landscape Restoration Plan will be prepared to ensure land is restored with native, original species that will need to be removed to allow construction of the Project. This Plan is based on the outcomes of the assessment in Chapter 13 Landscape and Visual.

In addition, the Project has committed to further reinstate parts of the sea cliff near Varvarovka that were impacted by geotechnical surveys during the Feasibility Phase, including replanting of juniper trees (see Chapter 11 Terrestrial Ecology and Appendix 11.2 Outline Cliff Reinstatement Plan of this ESIA Report).

Questions on potential emergency situations and emergency response measures, and whether the Project will record any Project-related accidents and comply with relevant safety measures.

The Project will comply with all national and international health and safety requirements, including requirements for documentation of accidents and incidents. Community and occupational health and safety is discussed in Chapter 15 Community Health, Safety and Security and Appendix 15.1 Occupational Health and Safety.

Emergency Response Plans (ERPs) will be prepared to ensure that emergency response procedures are implemented and understood. Further information, including risks and management measures, can be found in Chapter 19 Unplanned Events and Chapter 22 Environmental and Social Management.

At the Russian landfall facilities, Emergency Shutdown (ESD) valves and safety systems will be installed for each pipeline, which will automatically detect any non-standard operating conditions and stop the flow of gas immediately.

Continued...
Concerns related to seismic activity such as earthquakes, which could cause changes to soil and seabed and/or impact the Pipeline.

Seismic studies have been undertaken to ensure the Project design is suitable to the ground conditions and is not affected by any potential seismic activities. In order to minimise the effect of potential displacement from seismic activity, each pipeline will be laid in an enlarged trench. In certain sections, the pipelines will be laid on a bed of sand and backfilled with loose sand rather than the previously excavated soils. The combination of the wider trench and backfilling with loose sand allows the pipelines to move in a lateral direction should there be any movement by the fault, thereby lowering the risk of damage to pipeline integrity.

Seismic activity and potential risks related to the Project are described in Chapter 7 Physical and Geophysical Environment. The information on the seismic studies and the design of the Project design to ensure safety was communicated to stakeholders during the Scoping meetings in December 2012 and safety and design issues were included in the EIA Report which was publicly disclosed in the second quarter of 2013.

**Socio-Economic**

How will local communities benefit from the Project?

Questions about job creation, local hiring, and procedures for advertising available positions.

Project expenditures will result in demand for local goods and services (particularly during construction). In addition, some direct employment related to unskilled and semi-skilled positions may take place. Both procurement and employment will make a temporary and limited but beneficial contribution to the local economy.

The majority of employment related to the construction of the Russian Sector of the South Stream Offshore Pipeline will be highly specialised and managed by the offshore construction contractor. Some, although limited, local employment opportunities may be available through the construction contractor, and South Stream Transport has requested the construction contractor to advertise suitable positions locally and will encourage the contractor to hire local residents where practicable. Further information is provided in Chapter 14 Socio-Economics.

South Stream Transport is also developing a Community Investment Program. This will guide the company’s activities in the Local Communities beyond the direct scope of the Project, and may include support for local development initiatives. Through the Community Investment Programme, South Stream Transport will work with local stakeholders to identify suitable community investment opportunities.

**Comments**

<table>
<thead>
<tr>
<th>Potential impacts on the coastline, and therefore on tourism activities.</th>
<th>An assessment of potential socio-economic impacts, including impacts on local beaches and tourism activities, is provided in Chapter 14 Socio-Economics. The assessment concluded that residual impacts on specific businesses and on the tourism sector from Project activities will be not significant. The Project met with specific stakeholders such as Shingari Holiday Complex in the second half of 2013 and with local authorities, local tourism businesses and the local community in May 2014 to discuss Project activities and potential impacts on beach users and tourists.</th>
</tr>
</thead>
<tbody>
<tr>
<td>The potential impact on the leisure and recreation industry in Anapa Resort Town Municipal District should be assessed as part of the EIA.</td>
<td>An assessment of potential socio-economic impacts, including impacts on local beaches and tourism activities, is provided in Chapter 14 Socio-Economics. The assessment concluded that residual impacts on specific businesses and on the tourism sector from Project activities will be not significant. The Project met with specific stakeholders such as Shingari Holiday Complex in the second half of 2013 and with local authorities, local tourism businesses and the local community in May 2014 to discuss Project activities and potential impacts on beach users and tourists.</td>
</tr>
<tr>
<td>Will the Project have a negative impact on Sukko beach, which is a popular tourist destination?</td>
<td>An assessment of potential socio-economic impacts, including impacts on beaches and tourism, is provided in Chapter 14 Socio-Economics. During the construction of the Project, although no significant impacts on Sukko beach are expected, it is possible that beach users will be able to see construction vessels working in the sea for short periods of time. There may be a limited and short term (a few days at most) impact on water clarity during nearshore construction depending on the prevailing currents and wind conditions which has been assessed as having a low residual impact as part of the socio-economic assessment (see Appendix 12.2 Sediment Dispersion Study).</td>
</tr>
</tbody>
</table>

**Stakeholder Engagement**

How is the Project engaging with stakeholders? Stakeholders should be consulted on the need for the Project and emergency plans.

South Stream Transport has carried out stakeholder engagement in accordance with national regulations and following the standards and guidelines of international financing organisations along with Good International Industry Practice. Engagement activities to date have included the disclosure of various Project documents, community meetings, roundtable meetings, public hearings, and other meetings. Stakeholder engagement activities are described in this chapter (Chapter 6 Stakeholder Engagement) and in the Stakeholder Engagement Plan (www.south-stream-offshore.com).

Public opinion must be considered prior to Project implementation, as well as the cooperation and involvement of the press and administrative officials.

South Stream Transport values feedback and opinions from all stakeholders. Anyone interested in the Project can submit comments via email, post, or in person. South Stream Transport also regularly reviews media and other articles reflecting public opinion, concerns and perceptions, and engages with local administrations on issues related to the communities and regarding updates about the Project. Chapter 6 Stakeholder Engagement describes stakeholder engagement to date, including engagement with media, local officials and communities and the public, and the comments that have been received.

<table>
<thead>
<tr>
<th>Comments</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>All feedback should be addressed and included in the EIA Report.</td>
<td>All feedback, questions and comments received from stakeholders regarding the Project has been documented in the EIA and ESIA Reports. The EIA Report contains a record of the comments submitted during the EIA Report disclosure period along with questions asked at the EIA public hearing. The ESIA Report contains a summary of the main issues raised by stakeholders during both the EIA and ESIA processes and a list of comments made by stakeholders can be found in Appendix 6.1 Comments received during the Feasibility and Development Phases. Feedback, questions and comments received from stakeholders regarding the Project have also been considered in the development of both the EIA and ESIA reports. The development of design controls and proposed mitigation measures has considered stakeholder feedback, for example the construction of road bypasses around the communities of Gai Kodzor and Varvarovka to reduce traffic and road safety impacts; the restriction on nearshore construction to avoid fish spawning season; the lift of the amphora from the seabed in order to prevent damage to the cultural heritage object from pipelaying activities.</td>
</tr>
<tr>
<td>Residents should be informed about the schedule for Project works, so that they can know when they will be taking place. This schedule should be presented and discussed at any meeting with local residents.</td>
<td>A schedule of works is included in the EIA, ESIA, and Non-Technical Summary which are disclosed to the public. Current schedules are also shared at meetings with stakeholders, including public meetings in the communities. Chapter 1 Introduction provides the schedule for the development of the Project, with additional details in Chapter 5 Project Description.</td>
</tr>
</tbody>
</table>

**Environmental Protection (Marine)**

Potential adverse impacts on the marine environment.  

Potential impacts on the marine environment have been assessed in Chapter 12 Marine Ecology, which has identified potential impacts related to underwater noise, dredging and other impacts. A series of mitigation and management measures are identified in this chapter, and no significant residual impacts are anticipated.

Continued...
### Comments and Consideration and Response

<table>
<thead>
<tr>
<th>Comments</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Will there be prohibited access for fishing and shipping?</td>
<td>During construction, a marine safety exclusion zone of between 2 and 3 km radius (depending on the location of the pipe-lay spread) around the pipe-laying vessel during pipe-laying will be required to avoid interactions between the Project's activities and existing marine traffic and fishing vessels. This exclusion zone will move with the pipe-laying vessel, and will restrict access for fishing or other activities. These construction restrictions will be lifted behind the pipe-laying spread as the spread moves forward. <strong>Appendix 14.1 Fisheries Study</strong> examined potential impacts on fishing grounds, access, and fish stocks and concluded there will be no significant impact.</td>
</tr>
<tr>
<td>Questions about potential impacts on fish migration routes and spawning areas, including impact from underwater noise.</td>
<td>An international specialist company from the UK prepared a separate fisheries study for the Project which can be found in <strong>Appendix 14.1 Fisheries Study</strong>. Local fishing companies and government institutions, were consulted during the ESIA process to assess fishing and migratory issues. The potential interaction between the construction schedule and activities and fish migration routes and spawning areas has been considered in both the EIA and ESIA Reports. No significant impact on fish migrations, or fisheries activities, in Russian waters is expected. Impacts on fishing are assessed in <strong>Chapter 9 Socio-Economics</strong>, while impacts on fish are assessed in <strong>Chapter 12 Marine Ecology</strong>. In order to avoid impacts during the sensitive spawning season, coastal construction will not be undertaken in May, when spawning takes place. Regarding noise, an acoustic impact analysis showed that sound levels generated by pipe-laying and trenching in the Black Sea will not cause mortality or injury to fish. To further reduce the impact of noise on marine species, mitigation measures will be implemented, including the gradual ramping up of vessel engines to allow fish to move away from noise sources. Fish monitoring will take place during construction. Overall, both <strong>Chapter 12 Marine Ecology</strong> and <strong>Appendix 14.1 Fisheries Study</strong> conclude that no significant impacts on fish or fisheries are anticipated. Further to the meetings undertaken as part of the preparation of the fishing study report, Project representatives met with fishing companies again in May 2014 to communicate the results of the study in advance of the disclosure if this ESIA Report.</td>
</tr>
</tbody>
</table>

*Continued...*
### Traffic

<table>
<thead>
<tr>
<th>Comments</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Increased Project traffic will impact on existing road network and local communities e.g. leading to the generation of dust and concerns over pedestrian safety.</td>
<td>A traffic assessment was conducted and is provided in <strong>Appendix 9.1 Traffic and Transport Study</strong>. The assessment concluded that the presence of the temporary bypass roads around Gai Kodzor and Varvarovka (see Table 6.5) will mean that construction vehicles will no longer travel through Gai Kodzor and Varvarovka, leading to less dust, traffic noise, traffic congestion and road safety issues for local communities. South Stream Transport will ensure that vehicles are clean, well maintained and follow designated construction routes to ensure disturbance and the risk to pedestrian safety is minimised on all Project access routes. Meetings with the Gai Kodzor local administration in early 2014 confirmed that the traffic and road quality issues in Gai Kodzor were resolved with the construction of the bypass road and the completion of the related road repairs. The bypass road around Varvarovka will result in some noise impacts for some residents of North East Varvarovka living near the proposed bypass and mitigation measures have been proposed to address this impact (see <strong>Chapter 10 Noise and Vibration</strong>). Site visits and specific consultation with the local authority have been undertaken in early 2014 in relation to potential road impacts in the community of Rassvet and mitigation measures proposed (see <strong>Chapter 15 Community Health, Safety and Security</strong> and Appendix 20.1 Environmental Impacts of Associated Facilities: Russkaya Compressor Station).</td>
</tr>
</tbody>
</table>

| Will additional roads be constructed for the Project? | A number of permanent and temporary (i.e. construction) roads will be constructed and used for the Project, including: the Gai Kodzor bypass road (already constructed by Gazprom Invest); the Varvarovka bypass road (which will be a permanent road but will only be used by the Project during the Construction Phase and not during the Operational Phase); a permanent access road to the landfall facilities (2.6 km constructed by Gazprom Invest and a short 200 m spur to the landfall facilities constructed by South Stream Transport); and a temporary access road from the permanent access road to provide access to the microtunnel construction site. Roads and other facilities are detailed in **Chapter 5 Project Description**. |

*Continued...*
### Comments

#### Project Location, Routing and Alternatives

Have other alternative options been considered? Why was Anapa selected, instead of Novorossiysk, Sochi, Gelendzhik or Temryuk?

When defining the route, the technically and financially feasible alternatives were considered along with the related environmental and social characteristics and issues. This process is described in Chapter 4 Analysis of Alternatives. These studies concluded that the selected landfall location in Anapa provided the optimal solution along the Russian Black Sea coast.

Information about Project alternatives, the selection of the landfall location, safety standards, and impacts on communities have been discussed in previous meetings, including community meetings during the Feasibility Phase, meetings related to the Scoping Report and to the draft EIA Report. Potential impacts on residents of nearby communities, and how these will be mitigated, are described in Chapter 9 Socio-Economics.

#### EIA/ESIA Processes and Reports

How is the Project managing impacts?

Potential impacts from the Project have been assessed in accordance with national legislation and following the standards and guidelines of international financing organisations. In each chapter of the impact assessment, design controls and mitigation measures are identified to manage, reduce or avoid adverse impacts. These measures will be incorporated into the management plans which will be put in place to manage and monitor impacts and ensure the mitigation measures are implemented in accordance with the EIA and ESIA Reports during the Construction and Operational Phases of the Project. Further details are set out in Chapter 22 Environmental and Social Management and in each assessment chapter (chapters 7 to 18).

Continued...
<table>
<thead>
<tr>
<th>Comments</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>There should be one single EIA that meets both Russian and international requirements and covers both the South Stream Offshore Pipeline and the Russkaya Compressor Station.</td>
<td>The entire South Stream Gas Pipeline System spans over 2300 km, crossing a number of countries and different geographies to transport natural gas from Russia to the countries of Central and South-Eastern Europe. It is not unusual for a project of this size to be divided into separate elements due to the fact every country has its own regulations in which the Project must comply. In addition, the offshore component of the Pipeline System through the Black Sea is very different from the onshore sections in terms of technical design, engineering and construction methods, as well as with respect to the surrounding environment. As such, it made sense to evaluate the offshore section separately. With respect to the EIA and ESIA, these two documents are designed to meet different requirements are often different in methodologies and approach, as well as content. South Stream Transport is making efforts to ensure that stakeholders understand the differences and similarities between these two processes. All feedback received as part of both processes has been considered in the development of this ESIA Report.</td>
</tr>
<tr>
<td>Carrying out both EIA and ESIA processes in Russia complicates assessment and creates confusion, especially two stakeholder engagement processes.</td>
<td></td>
</tr>
<tr>
<td>How will information collected during the assessment process influence decision-making and the ESIA Report?</td>
<td>Baseline information has been collected through a wide range of methods including through scientific surveys, consultation with authorities, administrations and other organisations, local communities and site visits. This information is analysed and used to carry out the impact assessments. All data and feedback collected is considered in the ESIA Report, informing the understanding of the baseline, potential impacts and receptors, and the development of mitigation and management measures. This process has been explained at all public meetings related to the Project and is also explained in the introduction to other stakeholder meetings that have been held as part of the baseline data collection and stakeholder engagement for the Project.</td>
</tr>
</tbody>
</table>

**Noise and Vibration**

Project generated noise and vibration, particularly during construction, could adversely affect communities e.g. Varvarovka and Sukko. Noise and vibration from increased traffic will impact houses causing cracks and wear.

**Chapter 10 Noise and Vibration** assesses the potential impacts on local communities and residences. With mitigation, including the Gai Kodzor and Varvarovka bypass roads which will reduce the number of heavy goods vehicles travelling through both communities, no significant impacts on residences in these communities are expected from traffic generated noise and vibration.

<tr>
<th>Visual Amenity and Viewscapes</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visual impact of Project vessels in the nearshore section of the Project.</td>
<td>An assessment of potential visual impacts has been undertaken to include vessels up to 10 km away from the Russian shore (see <strong>Chapter 13 Landscape and Visual</strong> for more detail). There will be views of construction vessels experienced by the residents and visitors of Sukko, Anapa, and the private beach at the Shingari and Don holiday complexes. These impacts will be temporary and short-term and measures will be put in place to reduce impacts, including shielding of night time lighting on board vessels.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Cultural Heritage</th>
<th>Consideration and Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cultural heritage along the Pipeline route should be protected.</td>
<td>A cultural heritage assessment has been undertaken (<a href="#">Chapter 16 Cultural Heritage</a>) to ensure that impacts on cultural heritage objects and sites appropriately avoided or mitigated. Consultation was undertaken with a number of cultural heritage experts and organisations in 2013 to discuss potential impacts and these discussion informed the design control and mitigation measures outlined in this document. The approach to the protection of cultural heritage was also outlined in the EIA documentation which was publicly disclosed in the second quarter of 2013.</td>
</tr>
</tbody>
</table>

A number of stakeholders also highlighted benefits that the Project will bring, including anticipated investment in the local area and the development of infrastructure in Sukko and Varvarovka. In addition, some stakeholders thought that the Project could generate new jobs and felt positive that the EIA and ESIA processes would ensure that the opinions and suggestions of stakeholders would be considered.

### 6.6 Conclusions

Comments received from stakeholders to date, whether verbally or in writing (and irrespective of whether or not the primary purpose of the meeting was to seek comments on the scope of the ESIA) have been considered and addressed, where relevant, in this ESIA Report. Comments from stakeholders have informed the baseline studies, the identification and assessment of impacts, and the definition of mitigation and management measures.

Feedback from stakeholders over the impacts of Project traffic on safety, road condition and dust in Varvarovka led South Stream Transport to investigate the potential to construct a bypass road to avoid having to send large amounts of project Heavy Goods Vehicle (HGV) traffic through Varvarovka. This investigation involved surveys and consultation with landowners. Following this survey and consultation work, a suitable bypass route was chosen that will significantly reduce the concerns of stakeholders. This example demonstrates how stakeholders have informed the ESIA processes and influenced Project design.
Stakeholders have also emphasised the need to ensure an effective, transparent and inclusive stakeholder engagement process, including regular updates about Project activities. Stakeholders have been engaged for data collection, and to validate and gain further understanding of the baseline conditions.

The Project is committed to on-going stakeholder engagement and welcomes feedback and comments from stakeholders over the life of the Project. The Stakeholder Engagement Plan will be periodically updated as the Project progresses through, and beyond, construction.

7 Physical and Geophysical Environment

7.1 Introduction

This chapter provides a description of the physical and geophysical environment associated with the South Stream Offshore Pipeline – Russian Sector (the Project). The chapter provides context and background to the detailed baseline studies contained within the environmental and social assessment chapters which follow.

Attributes discussed in this chapter comprise:

- **Physical Environment:**
  - Meteorological conditions;
  - Electromagnetic fields;
  - Radiation;
  - Oceanography; and
  - Marine Water Quality.

- **Geophysical Environment:**
  - Tectonic setting and geology;
  - Seismicity (including terrestrial and marine geohazards);
  - Terrestrial and Marine Geomorphology; and
  - Marine Sediments.

Where possible, the physical characteristics described in this chapter apply to the overall Project. However, where specific characteristics were observed to be variable across the landfall section, nearshore section and offshore sections of the Project, this is specified.

Receptors sensitive to the terrestrial environment include soil, groundwater, surface water and landscape. These receptors are discussed in detail in Chapter 8 Soils, Groundwater and Surface Water and Chapter 13 Landscape and Visual. The terrestrial physical environment may also influence ecological receptors; these receptors are discussed in Chapter 11 Terrestrial Ecology.

The receptors sensitive to the changes in the marine environment are, for the most part ecological ones, and the significance of any such changes are discussed in detail in Chapter 12 Marine Ecology.

Potential environmental issues associated with geohazards and seismicity are discussed further in Chapter 19 Unplanned Events.
7.2 Spatial and Temporal Boundaries

7.2.1 Project Area

The Project Area (as described in Chapter 1 Introduction) is subdivided into three sections: the landfall, nearshore and offshore sections. This chapter considers all three sections.

7.2.2 Study Areas

The Terrestrial Study Area is a zone extending up to approximately 1.5 km either side of the centreline of the pipeline route and landfall facilities boundary. The Terrestrial Study Area has been assessed within a regional context with respect to the geology. The Terrestrial Study Area is bounded to the southwest by the coast.

The Marine Study Area is a zone of variable extent either side of the centreline of the pipeline route. The Marine Study Area is wider in the coastal waters and on the continental shelf and slope than it is in the deep waters of the abyssal plain. The Marine Study Area is bounded to the northeast by the coast and to the west by the edge of the Russian EEZ.

7.2.3 Survey Areas

The Terrestrial Survey Area for the physical environment is the same as the Terrestrial Study Area. The Marine Survey Area is typically the same as the Marine Study Area. The Marine Survey Area has varied over time as the pipeline routing has been refined.

7.3 Baseline Data

7.3.1 Methodology and Data

In order to provide context for the assessment of environmental impacts (discussed in subsequent chapters), baseline information on the physical environment, geology and oceanography of the region has been collected.

Secondary (i.e. existing data based on desk-based research) and primary data regarding the relevant baseline characteristics have been identified and assessed. Primary data was then collected during field surveys.

7.3.2 Secondary Data

Contextual information on the regional setting was obtained through literature review. Meteorological data for the region was sourced from published datasets.

Published geological, seismological and topographical maps were reviewed to characterise the regional tectonic setting, geology and geomorphology.

Background information on the oceanography and hydrography of the Black Sea has been based (Ref. 7.1) on the hydro-environmental database of the Southern Branch of the Institute of...
Ocean Sciences of RAS (Gelendzhik City) (Ref. 7.2). This dataset includes results from 82 survey voyages (1756 stations) undertaken between 1924 and 2012 in the area from 43° to 44.5°N and from 38° to 39.5°E. Background information is available on contamination of marine waters and sediments based on previous surveys (Ref. 7.1).

Additionally, the Black Sea Commission State of the Environment report (Ref. 7.3) was used to provide additional baseline data on the region.

### 7.3.3 Baseline Surveys

A number of onshore and offshore engineering and environmental surveys have been undertaken to aid the engineering design and the ESIA process. These surveys are detailed in Table 7.1. The surveys were undertaken between 2009 and 2013 and covered the following aspects of relevance to this chapter:

- Meteorological conditions;
- Electromagnetic fields and radiation;
- Seismicity;
- Geology;
- Geomorphology;
- Marine oceanography and setting; and
- Marine sediment and water quality.

The baseline data presented in this chapter is predominantly based on published literature and the information gathered during these surveys (Refs. 7.1, 7.4, 7.5, 7.6, 7.7, and 7.8).

### Terrestrial Surveys

Field surveys were undertaken to assess electromagnetic fields and radiation levels (Ref. 7.1, 7.7). The majority of the field measurements and samples were located within or near the terrestrial Project Area.

The electromagnetic survey comprised measurements of the background electric and magnetic field intensity at five locations across the Terrestrial Survey Area (Figure 7.1). The measurements were recorded at an industrial frequency of 50 Hz. The locations sampled all represented potentially high emitting electromagnetic sources across the Terrestrial Survey Area, such as high voltage power lines, outdoor switchgears and transformer units.

Background radiation levels were measured across the Terrestrial Survey Area:

- Measurements of gamma radiation were recorded at a total of 134 control points across the Terrestrial Survey Area with 81 measurements taken during the 2010 survey, and a further 53 measurements taken during the 2011 survey (Figure 7.1);

- The equivalent dose rate\(^1\) for external gamma radiation was then determined for a total of 1144 points in the Terrestrial Survey Area (Figure 7.1). Measurements were undertaken at

---

\(^1\) The equivalent absorbed radiation dose (equivalent dose), measured in sievert per hour (Sv/h) is a measure for assessing the health risk of radiation exposure. It is a calculated average measure of the radiation absorbed by a fixed mass of biological tissue that attempts to account for the different biological damage potential of different types of ionizing radiation.
175 points during the 2010 survey, 555 points during the 2011 survey, and 414 points during the 2013 survey; and

- In addition, a total of 42 soil and stream bed sediment samples (Figure 7.1) were collected within the Terrestrial Survey Area. The samples were analysed in order to assess the levels of various radioactive isotopes. In total, 20 samples were collected during the 2010 survey, seven samples were collected during the 2011 survey, and 15 samples were collected during the 2013 survey.

The same Terrestrial Survey Area (Figure 7.1) was used for the geomorphological mapping. Additionally, soil and water samples were collected for analysis; this is discussed in Chapter 8 Soils, Groundwater and Surface Water.

Geotechnical and geophysical surveys were undertaken along the Pipeline route within the same Terrestrial Survey Area. The geotechnical surveys have included drilling boreholes up to 180 m deep to confirm the ground conditions. Soil and rock samples were collected from the boreholes for geotechnical testing. The geophysical surveys included seismic refraction and electrical tomography profiling to aid interpolation of the ground conditions between boreholes.

7.3.3.2 Marine Surveys

To complement the data obtained from desk studies, several marine surveys specific to the Project have been undertaken (Table 7.1).

A metocean survey of the pipeline route across the Black Sea was undertaken between 2010 and 2012 (Ref. 7.4). The survey locations are shown in Figure 7.2.

File Name: I:\5004 - Information Systems\46369082_South_Stream\MXDs\Report Maps - Russia\Russian ESIA\Chapter 7 Physical and Geophysical Environment\Figure 7.1 Location of electromagnetic and Radiation Sampling Points.mxd
Marine water quality surveys were undertaken (Ref. 7.1) in autumn 2010 and spring 2011. Water quality analysis for general hydrochemistry and potential pollutants was undertaken. Water sampling for laboratory analysis was undertaken in accordance with GOST 17.1.5.05-85 'General requirements for sampling of surface and sea waters'. (Ref. 7.9) Measurements of water temperature, salinity and density were undertaken in situ through the water column using a winched probe. Meteorological and oceanographic measurements were also obtained during these surveys.

In November 2010, a total of 23 water samples were collected at eight survey locations (known as stations). In April 2011, a total of 45 water samples were collected at 14 stations. The spring 2011 survey extended further from the coast and thus covered a larger area than the autumn 2010 survey. In addition, in summer 2011 chemical and bacteriological testing was undertaken at two additional locations: Station 4C near the coast line and 5C in shallow waters (Ref. 7.1). The locations of the marine water survey location stations are presented in Figure 7.3. The depths at which the water samples were collected are presented in Table 7.2.

Marine sediment sampling from the seabed was undertaken between 2010 and 2011 and in July 2013 (Ref. 7.1, 7.8). The 2013 survey included coring within the area to be dredged and areas of seabed intervention to establish levels of potential contamination within the sediment in these areas in line with the requirements of the London Convention for disposal of dredged material. The sampling locations are shown on Figure 7.4.
In total, 28 samples were collected during the 2010 and 2011 surveys (Ref. 7.1): 6 in autumn 2010, 8 in spring 2011 and 14 in summer 2011. During the 2013 survey (Ref. 7.8), 57 sediment samples for analysis of contaminants were collected from 42 locations: 43 grab samples from 35 grab locations and 14 core samples at 7 core locations. The sediment samples were visually described before undergoing chemical analysis and grain size distribution analysis. Data on sediment type at sample locations were also collected by analysis of grain size in sediment samples or ROV footage where sediment samples could not be collected. Further interpretation of the bathymetric surveys and ROV footage was undertaken in a report summarising the results is contained in Appendix 7.1 Abyssal Plain Report.

7.3.4 Applicable Standards

The policy, regulatory and administrative frameworks relevant to the Project and ESIA process are outlined in Chapter 2 Policy, Regulatory and Administrative Framework. In addition to these, there are a number of standards of specific relevance to this chapter. These comprise:

- International standards on electromagnetic fields:
  - International Finance Corporation (IFC) Environment, Health, and Safety Guidelines Electric Power Transmission and Distribution (Ref. 7.10); and
  - International Commission on Non-Ionizing Radiation Protection (ICNIRP) guidelines for Limiting Exposure to Time-varying Electric, Magnetic, and Electromagnetic Fields (Ref. 7.11).

- Russian national standards on electromagnetic fields:
  - Russian Standard SanPIN 2971-84 on Regulations for Public Protection Against the Impact of an Electrical Field Created by Overhead Power Lines with an Alternating Power of Industrial Frequency (Ref. 7.12); and
  - Russian standard GN 2.1.8/2.2.4.2262-07 on Maximum Permissible Levels of Magnetic Fields with a Frequency of 50 Hz in Residential Premises, Public Buildings and on Residential Territories (Ref. 7.13).

- Russian national standards on radiation:
  - Russian Standard MU 2.6.1.2398-08 on Radiation Monitoring and Sanitary Epidemiological Assessment of Land Plots for Construction of Houses, Buildings and Public Facilities and Industrial Projects with Regard to Radiation Safety (Ref. 7.14); and
  - Russian Standard SanPIN 2.6.1.2523-09 on Radiation Safety Standards (Ref. 7.15).

- Russian standards on marine water quality:
  - Order of the Federal Fisheries Agency No. 20 dated 18.01.2010, on Approving the Standards for Water Quality in Fishing Water Bodies, including Standards for Maximum Permissible Concentrations of Harmful Substances in the Water of Fishing Water Bodies (Ref. 7.16); and
  - Russian Standard SanPIN 2.1.5.2582-10 on Sanitary and Epidemiological Requirements for Protection of Sea Coastal Waters Against Pollution in Areas of Water Use of the Population (Ref. 7.17).

- Dutch standards on marine sediment quality (adopted in absence of equivalent Russian standards):
  - Circular on target values and intervention values for soil remediation, 2000. Ministry of Infrastructure and Environment of the Netherlands (Ref. 7.18). Recommended for use as a methodological guide by Russian Standard SP 11-102-97 'Environmental science surveys for construction'.
7.4 Physical Environment

7.4.1 Meteorological Conditions

The Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring has monitored long-term climatic characteristics for the period from 1977 to 2009 (Ref. 7.1) at the nearest weather station to the Project, which is located in Anapa, 5 km north of the proposed pipeline route (Anapa WMO, Station ID 37001, Ref. 7.19).

The Study Area is characterized by a Mediterranean-type climate, with a sunny, hot and dry summer and a relatively mild and humid winter.

The average air temperature data is summarised in Table 7.3. The annual average air temperature in Anapa is 12.1 °C. On average, the warmest months are June to September with a maximum monthly average temperature of 21.0 °C. The coolest are November to March, with a minimum average temperature of 4.4 °C. The average maximum daily temperature is 29.0 °C and the average minimum daily temperature is -2.2 °C (Ref. 7.19). The absolute maximum and minimum air temperature during the period 1977 to 2009 is 38°C and -26°C, respectively.

The annual average precipitation is 539 mm (an average of 45 mm per month), mainly in the form of rain (Figure 7.5). The maximum recorded daily precipitation is 85.9 mm. There is relatively limited seasonal variation in precipitation, with the greatest amount occurring during the months of November, December and January.

The deepest snowfall on record is 33 cm, though snowfall is generally sparse in comparison with the rest of the region and the Russian Federation. Snowfalls usually occur between November and March. Blizzard conditions can occur during winter storms. Frosts occur between October and April.
Table 7.4 presents the maximum number of recorded days with fog by month. It shows that May has the maximum number of fog days with nine fog events. August has the least number of fog days, with an average of one day with fog.

Wind conditions vary seasonally. The summer is characterised by light breezes whereas squally winds are characteristic in winter. The average annual wind speed in Anapa is 4.8 m/s. The wind speed is over 13 m/s less than 5% of the time. Wind speeds of up to 40 m/s have been recorded at Anapa. Table 7.5 presents the wind statistics by geographic direction for Anapa.

Hourly sequential meteorological data has been sourced from the nearest available meteorological station, Anapa WMO (Station ID 37001), for the period 2008 to 2012 inclusive.
Anapa is located on the coastline of the Black Sea and is, therefore, sufficiently similar to conditions at the Terrestrial Study Area (Figure 7.6).

Figure 7.6 Wind Rose, Anapa Meteorological Station (Ref. 7.1)²

² The vertical axis on each wind rose represents the frequency (number) of measurements that are in a given sector.
The wind direction is predominantly from the northeast onshore with secondary winds from the south and southwest offshore (Figure 7.6). On average wind speed is slightly stronger from the south than from the northeast.

Wind monitoring has also been undertaken at sea in 2011 in the Marine Survey Area (Figure 7.2) as part of the metocean surveys (Ref. 7.6). The measured wind speeds were typically between 2 and 7 m/s with maximum wind speeds of up to 21 m/s during the survey period. The measured data were compared with hindcast and satellite data for the period 1992 to 2011 (Ref. 7.4, 7.6). The wind data was then modelled to predict wind statistics for the Marine Study Area (Ref. 7.6). The data shows that the wind speeds in the Marine Study Area during the survey period are approximately the same as the long-term wind speeds (Ref. 7.6).

The wind regime varies seasonally (Figure 7.7). Winds are stronger in winter with greater variability in wind direction. The seasonal variation in the wind regime is illustrated by Figure 7.7. The predicted normal and extreme wind conditions are presented in Tables 7.6 and 7.7.

7.4.2 Electromagnetic Fields

Electric and magnetic fields (EMF) are invisible lines of force produced by electrical devices, such as power lines and electrical equipment. Electric fields are produced by voltage and increase in strength as the voltage increases. Magnetic fields result from the flow of electric current and increase in strength as the current increases (Ref. 7.10).
Table 7.8 presents the results of the electric and magnetic field survey compared against both ICNIRP and Russian recommended exposure limits (Ref. 7.11 and 7.13, respectively). The results of the electromagnetic survey indicate that the background electric and magnetic field measurements recorded were within both the ICNIRP and Russian peak exposure limits for the prevention of adverse indirect effects for more than 90% of exposed individuals of the general public (Ref. 7.1).

### 7.4.3 Radiation

Background radiation levels associated with the Terrestrial Survey Area were assessed during surveys carried out in 2010, 2011 and 2013 (Ref. 7.1, 7.7). 

#### 7.4.3.1 Gamma Radiation Levels

Results of the surveys across the Terrestrial Survey Area recorded the following background gamma radiation levels:

- 2010 survey: background gamma radiation levels ranged from 0.10 to 0.15 microSieverts per hour (μSv/h), with an average of 0.11 μSv/h;
- 2011 survey: background gamma radiation levels ranged from 0.04 to 0.15 μSv/h, with an average of 0.09 μSv/h; and
- 2013 survey: background gamma radiation levels ranged from 0.08 to 0.15 μSv/h, with an average of 0.1 μSv/h.
All measurements taken were assessed to be normal for gamma background levels, and did not exceed the Russian limits for anomalous levels (defined as readings of greater than twice the average background gamma radiation levels or 0.3 μSv/h) (Ref. 7.14).

### 7.4.3.2 Equivalent Dose of Gamma Radiation

The average equivalent dose of gamma radiation levels in the area were calculated to range from 0.09 to 0.13 μSv/h across the Terrestrial Survey Area, as follows:

- **2010 survey:** calculated equivalent dose of gamma radiation ranged from 0.08 to 0.15 μSv/h;
- **2011 survey:** calculated equivalent dose of gamma radiation ranged from 0.06 to 0.14 μSv/h; and
- **2013 survey:** calculated equivalent dose of gamma radiation ranged from 0.07 to 0.13 μSv/h, with an average of 0.1 μSv/h.

These levels were within acceptable background levels, and met the requirements of the Russian guidelines for assessing radiation safety (Ref. 7.14).

### 7.4.3.3 Radioactive Isotopes

Samples of soils and stream bed sediments were analysed using gamma spectroscopy methods to assess the levels of radioactive isotopes including: Radium-226 (\(^{226}\text{Ra}\)), Thorium-232 (\(^{232}\text{Th}\)), Potassium-40 (\(^{40}\text{K}\)), Caesium-137 (\(^{137}\text{Cs}\)) and Strontium-90 (\(^{90}\text{Sr}\)).

Elevated levels of \(^{137}\text{Cs}\) in the environment are associated with nuclear testing in the atmosphere (during the last century) and emissions from nuclear accidents at nuclear power facilities. The behaviour of the \(^{137}\text{Cs}\) isotope in the soil is controlled largely by the processes of particle absorption, migration of isotope carrying particles and erosion processes.

In general, \(^{137}\text{Cs}\) levels measured in the soils within the Terrestrial Survey Area were predominantly within the range expected for background soil levels (Ref. 7.1):  

- Of the 42 samples taken, the measured specific activity of isotope \(^{137}\text{Cs}\) recorded in 26 samples was below detection limits of five Becquerels per kilogram (Bq/kg). In a further 14 samples the measured specific activity of isotope \(^{137}\text{Cs}\) recorded was within anticipated background levels associated with radiation falling to the ground, i.e. within 5 to 15 Bq/kg (Ref. 7.1);  
- Two samples recorded isotope \(^{137}\text{Cs}\) activity above background levels (15 Bq/kg). The maximum recorded \(^{137}\text{Cs}\) activity value of 22 Bq/kg was recorded during the 2010 survey. However, these values were still within acceptable limits (Ref. 7.14) and

---

4 The equivalent dose (or equivalent absorbed radiation dose) is a computed average measure of the radiation absorbed by a fixed mass of biological tissue that attempts to account for the different biological damage potential of different types of ionizing radiation.
Isotope activity levels for $^{90}$Sr were measured in 20 soil samples taken from the 2010 survey only (Ref. 7.1). The activity levels measured for isotope $^{90}$Sr ranged from 0 to 47 Bq/kg (with an average measured value of 24 Bq/kg recorded) within the Terrestrial Survey Area and were within normal background levels.

Isotope activity levels recorded for natural radionuclides $^{226}$Ra and $^{232}$Th and $^{40}$K in soils within the Terrestrial Survey Area were found to be within normal background levels (Ref. 7.15):

- Isotope activity levels for $^{226}$Ra were typically well below normal natural background levels of 20 to 50 Bq/kg. Measurements of isotope activity levels for all 42 samples were at or below natural background levels, with measurements ranging from 8 to 27 Bq/kg for $^{226}$Ra;
- Isotope activity levels for $^{232}$Th measured in the soils ranged from 9 to 32 Bq/kg and were within normal natural background levels for $^{232}$Th (20 to 50 Bq/kg);
- Isotope activity levels for $^{40}$K measured in the soils ranged from 88 to 513 Bq/kg and were within or below normal natural background levels for $^{40}$K (200 to 800 Bq/kg); and
- Effective specific NRN activity in the soils ranged from 32 to 114 Bq/kg. These values are well below the Russian threshold intervention level of 370 Bq/kg permitted for building materials at public buildings and facilities (Ref. 7.15).

7.4.3.4 Summary

Results of the radiation survey indicate background radiation levels within the Terrestrial Survey Area meet the requirements of the Russian Standards on radiation protection. Radiation levels measured in the soils do not pose a risk to human health in terms of radiation exposure.

7.4.4 Oceanography

7.4.4.1 Bathymetry

The bathymetry of the Russian Sector of the Black Sea is shown in Figure 7.9.

The Black Sea is a semi-enclosed sea connected to the shallow (10 to 20 m deep) Azov Sea through the Kerch Straits and to the Mediterranean Sea through the Bosporus Straits, the Marmara Sea and the Dardanelles Straits. The flat abyssal plain (at a depth of 2,000 m) rises to the continental shelves. The north western shelf, with a mean depth 50 m, has a shelf break at about 100 m depth between the Crimean peninsula and Varna in the south.

The Russian continental shelf is gently inclined towards the west and extends to a water depth of 100 m (Ref. 7.1). Beyond 100 m depth, the continental slope starts dipping steeply to the west; it is characterised by patterns of ridges and canyons. The slope angle decreases towards the base (at 1,900 m depth) and typically varies from 27° at the top to 5° at the bottom.

The oceanography of the Black Sea has been assessed based on published datasets (Refs. 7.3, 7.35, 7.36, 7.37) and using Project survey data (Refs. 7.1, 7.4, 7.6).
7.4.4.2 Sea Level Variation

The Black Sea is practically non-tidal with a maximum range of no more than 0.1 m. Changes in water levels in the Black Sea are thus primarily caused by one or more of the following factors:

- Inter-annual fluctuations in the sea level;
- Seasonal fluctuation as a result of seasonal atmospheric dynamics (e.g. temperature, wind, rainfall and storms);
- River flows;
- Spatial changes in the atmospheric pressure; and
- Natural temporal and spatial variability in dynamics of the water column.

Long-term data collected (for approximately the last 90 years) along the Caucasian coast shows a slight yearly increase in mean sea level of about 0.23 cm per year (Figure 7.8), while the water level of the Black Sea is subject to seasonal fluctuations of about 20 cm (Figure 7.10). Long-term average seal level data is presented in Table 7.9.

Figure 7.8 Changes in Sea Level in the Black Sea from 1917 to 2005 (Ref. 7.1)
Figure 7.10 Deviation in Average Sea Level from 1917 to 2005 (Ref. 7.1)

![Figure 7.10 Deviation in Average Sea Level from 1917 to 2005](image)

</table>
Much more significant sea level variations have, however, occurred during the Quaternary Period, which are associated with global climatic variations, ice sheet collapse and the regional tectonic events that led to the opening of the Bosphorus Strait. There has been considerable scientific debate about the timing and process of the transition from the Black Sea lake at the end of the last ice age to its present mode. Over the past 30,000 years sea levels have varied due to periods of low river input during cold periods and major river inflow during periods of ice melt (Ref. 7.36). The timing of the most recent reconnection of the Black Sea with the Mediterranean is estimated to be 9,000 years BP (Ref. 7.36). This caused a transition from freshwater to marine conditions and resulted in the inundation of coastal landscapes. These transgressions caused wide spread shoreline regression in some locations and led to significant wave based shoreline erosion. The refilling of the Black Sea once the reconnection with the Mediterranean was established is estimated to have occurred over about 100 years but the transition from freshwater to marine conditions is estimated to have taken about 900 years beginning with the deepest water (Ref. 7.36). The transition was completed by about 7,700 years BP at mid water depths and by about 7,200 years BP on the shelves (Ref. 7.36).

Inundation of prehistoric habitations and reworking of cultural materials within the sediments is discussed further in Chapter 16 Cultural Heritage.

### 7.4.4.3 Wave Climate

The wind regime in the Russian part of the Black Sea is defined by the air mass transfer with a south-southwest to north-northeast direction, which is typical for the moderate zone of the Northern hemisphere. The winter is characterized by squally northerly, north-eastern and easterly winds, as a result of the increased Mediterranean cyclone activity and the existing anticyclone activity above Eastern Europe.

The prevailing winds in the Russian part of Black Sea are from the southwest. The highest wind speeds usually are registered during November to March when the hurricane north-eastern wind (bora) winds may bring gusty winds and cold temperatures to the coastline. The Russian coastline experiences approximately 15 to 20 storm days each winter, with wind speeds reaching up to 20 m/s approximately once a year.

The wave climate adjacent to the Russian coastline of the Black Sea is heavily influenced by the shallow continental shelf. The limited fetch lengths result in smaller primarily wind driven waves. The relatively shallow continental slope affects entering waves by transforming their 2-dimensional (2D) spectrum due to bottom friction and wave breaking.

Estimation of wave characteristics based on archival data held by the Institute of Ocean Sciences has been undertaken (Ref. 7.1, 7.2). A typical yearly maximum wave height in the Marine Study Area has been estimated as 2.9 m, with a 1 in 100 year return period wave reaching 4.8 m. A summary of the wave characteristics based on archival data (Ref. 7.1, 7.2) is presented in Table 7.11 and Table 7.12.

Wave measurements were undertaken during the 2011 to 2013 metocean survey (Ref. 7.4); the station locations are shown on Figure 7.2. The results were correlated with a long-term satellite data (26 year dataset) (Ref. 7.6). The significant wave height\(^6\) predictions are presented in Table 7.13. The average significant wave height increases with distance from the shore to about 1 m offshore. Near the coast, waves are predominantly from the west and southwest. Offshore, there is additionally a north-northeast wave component due to the increased fetch.

\(^6\) Significant wave height is the average wave height of the 1/3 highest waves.

### 7.4.4.4 Storm Surges

Short-term sea level variations are also associated with varying meteorological conditions and can result in localised sea level surges of up to 1 m. However, storm surge levels along the Caucasus coast are typically less than 40 cm.

Surge predictions based on published data (Ref. 7.1) are presented in Table 7.14.

</tbody>
</table>

The frequency of storm surges in the Black Sea is lower than that in other regions of the world's oceans (Ref. 7.38). The gently sloping continental slope open to winds and waves is subject to storm surges. It is estimated that typical storm durations vary between 56 and 151 hours with an average duration of 95 hours (Ref. 7.39). Extreme storms have quite a short growth phase with an average duration of 61 hours. Hence, the typical storm pattern is characterised with fast growth, a rather durable energetic development phase and relatively prolonged decay.

### 7.4.4.5 Currents

The Main Black Sea Current (MBSC) affects the whole basin in one cyclonic (counter clockwise in the northern hemisphere) circular motion. A prominent feature in the upper layer circulation in the Black Sea is the so-called "Rim Current", a cyclonic current that follows the abrupt
continental slope and encompasses a cyclonic cell that occupies the basin. A diagram of the MBSC is shown in Figure 7.11.

The MBSC is directed counter-clockwise forming the two rings over the basin apron in the western and eastern parts of the Sea (referred to as the 'Knipovich spectacles' after the name of one of the Russian oceanographers who described the phenomenon). The MBSC is associated with a series of cyclonic and anti-cyclonic eddies in the cyclonic meanders. Outside the Rim Current, numerous quasi-permanent coastal eddies are formed as a result of 'wind curl' mechanisms and upwelling around the coastal apron (Ref. 7.36).

The MBSC is a 50 to 80 km wide flow within the upper 300 m of the water column and remains present during the entire year. The current is more distinct during summer and winter. On average, the current passes some 15 to 50 km from the Russian coast.

Figure 7.11 Main Black Sea Current (Ref. 7.1)

As shown in Figure 7.11, coastal currents in the Caucasus region are characterised by two diametrically opposite directions of water movement: north-western and south-eastern. The north-western flow direction is dominant over the south-eastern flow (approximate ratio is 85% and 15% respectively). The maximum velocity of the north-western current is between 0.3 to
0.5 m/s and between 0.5 to 0.8 m/s in the summer and winter respectively; in comparison, the maximum velocity of the south-eastern current is 30 to 50% less (Ref. 7.1).

Current speeds in the core of the MBSC typically flow at 0.3 to 0.6 m/s depending on synoptic, seasonal and inter-annual variability.

Based on the results of current data measurements in 1998-1999, the values of extreme current speeds on the shelf, continental slope and abyssal plain were estimated (Ref. 7.1). Current speeds are inversely proportionate to depth. The 1-year return period nearshore current velocity is approximately 0.7 m/s. The maximum velocity (1:100 years return period) is approximately 1 m/s. On the continental slope (depth 100 to 1700 m), the current velocity varies from 0.1 m/s (1:1 year return period) to 0.2 m/s (1:100 years). A similar pattern is observed in the current speeds on the abyssal plain.

Further surveys of marine currents have been undertaken from 2011 to 2012 (Ref. 7.6) with currents measured close to the pipeline route; the station locations are shown in Figure 7.2. This included monitoring of differences in currents with depth. The current measurements have been combined with hindcasting from long-term datasets to estimate potential current speeds (Ref. 7.6). Surface and nearbed current data for the Marine Survey Area are summarised in Table 7.15 and Table 7.16. Yearly variation in nearbed currents is estimated to be about 30% in the nearshore section and 20% in the offshore section of the Marine Study Area (Ref. 7.6). Only minor variations in surface currents, predominantly due to the wind conditions, are anticipated.

**7.4.4.6 Ice Period**

The northern part of the Black Sea and the Kerch Strait are normally covered by ice during winter (Table 7.17). Shore ice occurs regularly along the eastern and western shores of the strait. The ice normally occurs between December and April.

The ice period of the Anapa-Novorossiysk region is unique. Ice in the form of “shuga” (slush ice) is short-term, forming nearly every year, but it is rare for the sea to freeze over completely. Novorossiysk Bay froze completely twice in the past century: during the winters of 1924-25 and 1933-34. The width of the shore ice exceeded 200 m and the ice was up to 15 m thick.

Icing of vessels, hydro-engineering structures, and the near shore area occurs every year. And in this context, the most favourable period for engineering work is from May to October. The
key shelter ports are Novorossiysk, Anapa and Gelendzhik. Novorossiysk Port and the adjacent Tsemes Bay are normally ice-free in winter (Ref. 7.40).

Ice scour is caused by erosion of the sea bed where floating sea ice comes into contact with the sea bed. This is not considered to be a significant risk for the Project as the pipelines exit the microtunnels at a water depth 23 m depth and because sea ice is an infrequent occurrence in the Study Area.

7.4.4.7 Water Temperature

The Black Sea exhibits a characteristically layered pattern in the vertical distribution of water temperature (Ref. 7.1, 7.2, 7.3). There are three principal layers: the surface water layer, the low temperature layer and the deep layer (Figure 7.12). This thermal layering is influenced by the salinity stratification described below.

The surface water layer is typically 20 to 40 m deep. The temperature of the surface waters varies seasonally by around 16°C, ranging from about 9°C in February to about 25°C in August. Considerable short term fluctuations (from several hours to several days) are observed against the background of seasonal changes in temperature. In autumn, winter and spring, these fluctuations are only 1 to 2°C. In summer, short-term changes of water temperature can reach 9°C. These fluctuations are mainly due to interactions of diurnal (daily) solar radiation and local wind field effects.

Below the surface waters there is a low temperature layer. In this layer, water temperatures reach their minimum values of about 6 to 7°C. The low temperature layer typically extends from the base of the surface water layer at on average 35 m to about 110 to 120 m deep. The thickness of the low temperature layer varies annually in response to the antecedent weather conditions over the preceding winter.

The temperature of the low temperature layer varies seasonally but there is an observable lag of several months compared with the surface layer. Temperatures at the top and the core of the low temperature layer reach their minimums in March and May, respectively, compared with the minimum of the surface layer in February. Similarly, temperatures at the top and the core of the low temperature layer reach their maximums in October and February, respectively, compared with the August maximum in the surface layer.

Below the low temperature zone (>100 to 120 m), water temperatures gradually rise with depth to a nearly constant 8.9°C at 400 m depth. Minimal seasonal variation in water temperatures is observed at depth. The stratification of the Black Sea limits active vertical mixing of surface and deep waters, thus confining seasonal variations to the upper layers.
The 2011 survey data showed a similar pattern to the literature dataset (Ref. 7.1). Water temperatures varied with depth. In the surface layer, water temperature also decreased with distance from the shore (Figure 7.13). Water temperature in the surface waters ranged from 8.70 to 9.89°C. A thermocline was identified at around 40 to 45 m depth. Water at 100 m and 500 m depth was on average 8.43°C and 8.88°C respectively.

Measured seabed water temperatures ranged from 6.35 to 26.34°C in shallow waters (<20 m) (Ref. 7.6). The seasonal range in seabed water temperature decreases as water depth increases. By water depths of 100 m, the seasonal variation is less than 2°C. There is negligible seasonal variation in seabed water temperatures in water depths over 200 m. Seabed water temperatures in deep water areas are around 9°C (Ref. 7.6).
7.4.4.8 Water Salinity

Globally, typical marine salinity is about 35‰. In some inland seas where evaporation exceeds the input of the fresh water, salinity can reach up to 37 to 38‰ (for example, in the eastern part of the Mediterranean Sea) and even 40‰ (in the Red Sea). In comparison, in the Black Sea, salinity is considerably lower at about 22‰ than that of the Mediterranean Sea. This is due to the dominance of fresh water inputs and the limited water exchange with the Mediterranean.

The total volume of river flows and atmospheric precipitation entering the Black Sea exceeds evaporation by more than one third. This forms a surface layer of lower salinity. The deep water is more saline than the surface layer due to the inflow of saline waters into the Black Sea from the Mediterranean through the Bosphorus Strait.
The combination of these factors causes the Black Sea to exhibit strong vertical stratification in salinity. A typical depth profile for salinity based on long-term metocean datasets for the Russian EEZ (Ref. 7.1, 7.2) is shown in Figure 7.14. There is an upper layer of lower salinity water overlying a deep layer of more saline water. The permanent halocline in the Black Sea is located between 120 and 200 m water depth (Ref. 7.1, 7.2, 7.3). Salinity varies in the upper layer varies seasonally.

**Figure 7.14 Long-term Average Annual Profiles of Salinity with Depth (Ref. 7.1)**

![Salinity Profiles](image)

a) Summer Profile  
b) Winter Profile

Note: Average square deviations are marked by dotted lines.

Salinity at the sea surface is at a maximum in winter (18.2‰ in December) then reduces to a summer minimum (17.6‰ in August). In the upper layer, water salinity also increases with distance from the shore (Figure 7.15 and Figure 7.16). Salinity varies with depth (Table 7.18). Salinity levels rise rapidly to approximately 21‰ by around 200 m depth. The seasonal pattern in salinity reverses with depth within this zone; from about 25 m downwards salinity is higher in summer than in winter due to the lag time in vertical mixing. By 150 m depth, the salinity minimum is 19.9‰ from December to March and the maximum is 20.6‰ from August to September; the annual range of seasonal salinity change (0.7‰) at this depth is slightly higher that at the sea surface.

Beyond about 200 m depth, salinity levels continue to rise with depth but at a slower rate. Below 500 m, salinity is approximately 22‰ with no significant seasonal variation (Ref. 7.1). Seabed water salinity in the deep water areas is around 22.3‰ (Ref. 7.5).

### Figure 7.15 Sea Water Salinity (‰) in the Surface Waters in April 2011 (Ref. 7.1)
7.4.4.9 Water Density

During the year, water density changes as a function of salinity and temperature.

In the near-surface waters (0 to 10 m), the water density is at a minimum in July and August (10.44 conventional units), when temperatures are highest and salinity is lowest. In comparison, water density is at a maximum in March (14.02 conventional units) (Ref. 7.1, 7.2, 7.3).

Below the surface, density increases rapidly with depth (Figure 7.17) reflecting the increase in salinity and decrease in temperature. The vertical pattern in water density distribution is similar to the salt distribution pattern except that there is an increase in density at around 20 to 60 m relating to the low temperature zone at this depth. The pycnocline is typically higher and more distinct in the central seas as compared with the continental slope.

From 300 to 500 m, density increases slowly with depth. No significant seasonal trends are observed. Below 500 m, density is around 17 conventional units and is relatively constant with depth, mirroring the patterns observed in salinity and temperature.
The 2011 survey data (Ref. 7.1) showed a similar pattern to the literature dataset (Table 7.19). Water density varied with depth. In the upper layer, water density also increased with distance from the shore. As would be expected, the vertical and lateral distribution patterns for density were broadly similar to those for salinity. Density in the surface layer ranged from 13.08 to 14.05 conventional units with an average value of 13.73 conventional units. At 100 m and 500 m, the average density values were 15.75 and 17.02 conventional units respectively.

Figure 7.17 Long-term Average Annual Profiles of Conventional Density with Depth (Ref. 7.1, 7.2)

The relationship between salinity, temperature and density is key to appreciating the stratification of the Black Sea. This stratification has implications for water quality and for biological activity. Figure 7.18 shows the typical interrelationship.

7.4.5 Marine Water Quality

Understanding of marine water quality in the Black Sea requires an appreciation of the importance of stratification with depth. The upper sea layer experiences seasonal and year to year variation in hydrophysical and hydrochemical characteristics under the influence of external climatic factors. Its lower boundary is a deep pycnocline, below which influence of the external factors does not normally extend and hydrochemical conditions are relatively stable (Ref. 7.1). The upper layer is aerobic whereas anaerobic conditions exist at depth. The vertical zonation in hydrogeochemistry is illustrated in Figure 7.19.

All characteristic features of the depth distribution of hydrochemical parameters (horizons of wedging out of oxygen, hydrogen sulphide, and extreme values of biogenic elements) are usually located lower in the Black Sea coastal zone than in the central areas. This domal structure to the stratification is connected with the cyclonic character of water circulation. However, the hydrochemical horizons are almost always at the same density levels, consistent with the importance of density stratification to hydrochemical processes. Note that the upper boundary of the anaerobic zone exactly corresponds to a specific isopycnic surface (water density).
7.4.5.1 Oxygen

Oxygen is present in the surface waters, being at highest in concentration around 10 to 40 m depth. Oxygen concentrations in the surface waters vary seasonally, reflecting biological activity and the inverse relationship between oxygen solubility and water temperature. Oxygen concentrations in the surface waters are highest in March to May, which relates to the spring phytoplankton bloom and when surface water temperatures are relatively low. The minimum oxygen concentrations are in August to September when surface water temperatures are at their maximum.

Oxygen concentrations decrease from around 40 m depth, with oxygen depletion occurring in layers below 80 to 150 m (Figure 7.20). Oxygen disappears at a water density of about 15.9 conventional units. This is due to the salinity stratification limiting the potential for vertical mixing. Oxygen is typically absent from the deeper waters below the pycnocline, creating anoxic conditions; the Black Sea is the world's largest anoxic basin. Waters with hypoxic or entirely anoxic conditions are typically incapable of sustaining permanent populations of species dependant on aerobic respiration.
The average oxygen content of the surface waters was 8.91 mg/L in autumn 2010 (Ref. 7.1). Oxygen concentrations decreased below about 25 to 35 m; oxygen was not detected below about 100 to 140 m depth. In spring 2011, the oxygen content of the surface waters ranged from 10.10 to 10.35 mg/L. Oxygen concentrations decreased below about 30 m depth; oxygen was not detected below about 80 m depth.

Both autumn 2010 and spring 2011 surveys had similar spatial patterns in oxygen content (Ref. 7.1). Oxygen concentrations generally increased with distance from the coast. Coastal concentrations were highest near Gelendzhik and lowest near Anapa. The lower oxygen concentrations near the coast are interpreted to be due to warmer water temperatures near the coast, continental run-off and oxygen consumption by the oxidation of terrestrially-sourced organic matter.

In the summer 2011 survey (Ref. 7.1), the dissolved oxygen content in the surface layer of water in the coastal waters (as measured at coastal station "4C"; location on Figure 7.3) was 7.48 mg/L, which satisfies the Maximum Permissible Concentration (MPC) for human health in bathing waters set in SanPIN 2.1.5.2582-10 (Ref. 7.17).
7.4.5.2 Hydrogen Sulphide

The lack of oxygen at depth due to vertical stratification of the water column means that the potential for significant marine life occurring at depths of greater than 200 m within the Black Sea is likely to be limited to those organisms capable of anaerobic respiration (e.g. chemosynthetic life). Chemosynthesis typically produces hydrogen sulphide (H\textsubscript{2}S) and methane as by-products, although these molecules are also formed by other biological and non-biological processes.

The widespread presence of hydrogen sulphide at depth is a notable characteristic of the Black Sea. The deep part of the water column throughout the Black Sea is characterised by high concentrations of H\textsubscript{2}S. H\textsubscript{2}S first appears at a water density of about 16.1 conventional units. From surveys in spring 2011 (Ref. 7.1), the H\textsubscript{2}S upper boundary occurred at a depth of between 100 to 160 m in Russian waters (Figure 7.19). H\textsubscript{2}S concentrations increased with depth up to a relatively high value of 13.2 mg/L in depths exceeding 2,000 m.

The depth at which H\textsubscript{2}S appears varies seasonally, being deeper in winter. This is more pronounced in the shore areas compared with the deeper sea. This reflects seasonal changes in density as there is a close correlation between the conditional density and the appearance of H\textsubscript{2}S. There is typically minimal seasonal variation in H\textsubscript{2}S concentrations at depth.

7.4.5.3 pH

The surface waters of the Marine Survey Area are alkaline with a pH of around 8.2 to 8.3. Slightly lower pH levels have been recorded in the surface waters in and near river estuaries. Below 25 m, the pH decreases reaching 7.6 to 7.9 at the depth of H\textsubscript{2}S appearance (c.80 to 160 m). Thereafter, pH slowly decreases with depth to about 7.5 at 2,000 m.

Slight seasonal variation in pH occurs (<0.5 pH units) in the surface waters, with summer values typically being slightly higher than winter values in coastal areas but the inverse in open seas.

In autumn 2010, the pH of the surface waters ranged from 8.2 to 8.4. In spring 2011, the pH of the surface waters were slightly lower, typically about 8.2. The pH values decreased with depth, dropping sharply below 80 m to 7.6. In the deep waters (>2,000 m) the pH is about 7.4, which corresponds to the long-term average pH for the deep waters of the Black Sea (Ref. 7.1).

7.4.5.4 Alkalinity

The total alkalinity of the surface waters is on average 3.196 mg/L. Alkalinity increases with depth, being 4.100 to 4.787 mg/L at 2,000 m.

Alkalinity in the surface waters varies spatially and seasonally, reflecting variations in river flows and quality and in precipitation inputs.

Alkalinity values measured in the autumn 2010 and spring 2011 surveys were within typical ranges for the Black Sea (Ref. 7.1). Coastal concentrations in the surface waters increased northwards along the coast. Concentrations were lower in the vicinity of the MBSC and then
increased in the central part of the Eastern Black Sea. Alkalinity concentrations increased with depth.

7.4.5.5 **Silica**

Silica concentrations in surface waters are low at 0.1 mg/L. Low silica concentrations in surface waters reflect its intensive use in biochemical processes in the photosynthesis zone. Below 50 m, silica concentrations rise gradually to 8.5 to 11.2 mg/L at 2,000 m.

Silica concentrations vary seasonally and spatially. Concentrations are typically higher in coastal waters than in the open seas and are higher in winter than in summer.

In autumn 2010, silica concentrations in the surface waters ranged from 0.03 to 0.06 mg/L with an average value of 0.03 mg/L (Ref. 7.1). Concentrations were higher in the southern part of the Marine Survey Area. The silica concentrations increased with depth. Silica concentrations below 60 to 80 m exceeded 1 mg/L, with the maximum concentration of 6.51 mg/L being recorded at a depth of 1900 m.

In spring 2011, the silica concentrations in the surface waters were up to 0.2 mg/L (Ref. 7.1). Again, higher concentrations were observed in the south around Gelendzhik, reflecting river inputs in this area. Silica increases with depth, being on average about 6 mg/L at 1,000 m depth.

7.4.5.6 **Organic Matter**

Measurements of the biochemical consumption of oxygen (BOD5) have been undertaken to provide indirect measurement of organic matter in the water.

BOD5 is highest in the surface waters. Maximum concentrations in the surface waters in coastal areas are higher than in the open sea. Concentrations in coastal areas are relatively variable but have been measured up to 2.92 mg/L. BOD5 concentrations in the open seas are 0.1 to 0.6 mg/L. Organic matter decreases with depth. Beneath the pycnocline, BOD5 levels are typically 0.3 mg/L.

In autumn 2010, the BOD5 concentrations in the surface waters ranged from 0.09 to 0.47 mg/L with an average value of 0.31 mg/L (Ref. 7.1). In spring 2011, the BOD5 concentrations in the surface waters ranged were up to 1.03 mg/L. The measured BOD5 values are relatively low (compared with Maximum Allowable Concentrations (MAC) of 3 mg/L) and are consistent with background values in the Black Sea and a relative lack of significant water pollution by organic compounds.

Chemical Oxygen Demand (COD) measurements were also obtained in autumn 2010 and spring 2011 (Ref. 7.1). COD values reflect the total organic matter content of the sea water. Measured COD values ranged from 1.2 to 1.5 mg/L with an average of 1.37 mg/L in autumn 2010. Measured COD values in spring 2011 ranged from 0.7 to 4.5 mg/L with an average of 1.3 mg/L in the whole water column but from 0.9 to 1.5 mg/L with an average of 1.2 mg/L in the surface waters. COD concentrations were highest near the coast and lowest in the MBSC. The measured COD values typically fell within the range (1 to 2 mg/L) considered representative of "clean" water (Ref. 7.1).
No BOD5 or COD was detected in measurable concentrations in coastal waters during the summer 2011 survey.

**7.4.5.7 Turbidity and Suspended Sediments**

The optical properties (transparency and colour) of the Black Sea waters vary seasonally. In interpreting the seasonal patterns it should be noted that there is limited data available on typical optical properties in the sea water over winter. Spatial variations are also observed, with transparency typically being lower near the coast especially near river mouths.

Transparency in the eastern and central parts of the Black Sea is typically highest during summer when the volume of water discharged by rivers is lowest. Correspondingly, colour values are at their lowest at this time. Transparency is lowest and colour values are highest in spring due to phytoplankton blooms and snow melt flows. From autumn to spring, storm activity in shallow waters mobilises seabed sediments causing an increase in turbidity in coastal areas.

In April 2011 (Ref. 7.1), turbidity values at 10 m depth ranged from 0.11 to 15.47 relative units with an average value of 1.90 relative units. Turbidity declined with depth, with average values of 0.50, 0.25 and 0.08 relative units at 25, 50 and 100 m respectively. The depth profiles show a clear distinction between the more turbid, upper active layer and the less turbid deep layer.

The main source of suspended solids is from river waters, wave induced disturbance of seabed sediments, and airborne particles. At the Caucasus shores where there is little in the way of shallow waters, the river flows entering the sea are rapidly mixed into the deep water column. Up to the depth of 100 m, the vertical distribution of suspended solids is characterised by gradual decrease in their concentration.

In the autumn 2010 survey (Ref. 7.1) the measured suspended sediment concentration varied from 2.0 to 6.7 mg/L with the greatest concentrations within the water column occurring in the southern part of the Marine Survey Area.

In the spring 2011 survey (Ref. 7.1) the suspended sediment concentration varied across the Marine Survey Area from 2.0 to 41.3 mg/L. However the peak concentration of 41.3 mg/L was only recorded at one station, with all other concentrations being below 10 mg/L.

**7.4.5.8 Phosphorus Compounds**

Phosphorus compounds play a key environmental role, influencing biological productivity.

**Phosphates**

The vertical distribution of phosphates is controlled by density and redox conditions, reflecting the stratification of the sea (Figure 7.21).
Concentrations are lowest in the surface waters, particularly during active photosynthesis. Phosphate concentrations are typically higher in coastal areas than in the open seas, reflecting the influence of continental runoff. Surface concentrations in nearshore areas are typically 0.013 mg/L in winter and 0.028 mg/L in summer, compared with 0.009 mg/L in winter and 0.017 mg/L in summer in the open sea.

Phosphate concentrations increase below around 40 m, with a secondary maximum around 100 to 150 m depth, then decreasing slightly before rising again to around 0.45 to 0.48 mg/L when the density is around 16.2 conventional units. Concentrations at 2,000 m depth are of the order of 0.5 to 0.7 mg/L.

Phosphate concentrations vary seasonally. Concentrations are higher in summer than in winter. An increase in phosphate concentrations in both summer and winter has been observed in recent years.

In autumn 2010, phosphate in the surface waters ranged up to 0.004 mg/L with an average value of 0.001 mg/L (Ref. 7.1). Concentrations were highest near Gelendzhik (Figure 7.22). Maximum phosphate concentrations of about 0.2 mg/L were observed at the depth where hydrogen sulphide begins to appear.
In spring 2011, phosphate concentrations in the surface waters ranged from 0.002 to 0.005 mg/L, being highest in the northwest of the Marine Survey Area (Figure 7.22). Phosphate concentrations increase with depth, reaching 0.25 to 0.27 mg/L at 2,000 m.

In summer 2011, the measured phosphate concentration in the coastal waters was 8 mg/L (Ref. 7.1).

Phosphate content in the surface waters of the nearshore and offshore sections of the Marine Survey Area do not typically exceed the MAC for fisheries (0.15 mg/L) (Ref. 7.16).

**Figure 7.22 Spatial Distribution of Phosphate Concentrations in Surface Waters (Ref. 7.1)**

![Spatial Distribution of Phosphate Concentrations in Surface Waters](image)

a) Autumn 2010  
b) Spring 2011

**Total and Organic Phosphorus**

There is limited information available regarding total and organic phosphorus concentrations in the Black Sea.

Concentrations of total phosphorus in the surface waters of the Black Sea are typically 8 to 10 µg/L. Concentrations are usually highest near the coast as the main source of total phosphorus in the surface waters are coastal flows. Concentrations rise at the pycnocline to around 200 µg/L. Organic phosphorus concentrations are also relatively low in the surface waters. The spatial patterns in organic phosphorus concentrations are typically generally similar to those observed for total phosphorus.

In autumn 2010, total phosphorus concentrations in the surface waters ranged from 2 to 6 µg/L being 3 µg/L on average. Concentrations were higher near Gelendzhik and in the seaward part of the surface area (Figure 7.23).

In Spring 2011, total phosphorus concentrations in the surface waters varied from 8 to 10 µg/L in the MBSC to around 20 µg/L near the coast (Figure 7.23).
7.4.5.9  Nitrogen Compounds

In sea water, nitrogen is represented by inorganic (nitrate, nitrite, ammonium salts) and organic (humic and fulvic acids, proteins, amino acids, amines etc.) compounds. Nitrogen distribution is an important controlling factor in biological productivity.

Nitrate

Nitrites are predominantly present at around 50 to 150 m depth within the transition zone between aerobic and anaerobic conditions (Figure 7.24). Typical concentrations in this zone are around 0.1 to 0.2 mg/L. Nitrate concentrations are very low in the surface waters above 50 m, being typically 0.028 to 0.12 mg/L. Nitrate is absent at depth in the deeper anaerobic (H₂S) zone.

Nitrate concentrations vary seasonally, reflecting variations in biological activity. Nitrate concentrations are highest in winter, dropping markedly with the spring phytoplankton bloom before rising slightly in summer. There is a secondary drop in autumn reflecting increased phytoplankton activity. The seasonal variation is more marked at shallow depths.
In autumn 2010, nitrate concentrations in the surface waters ranged from 0.003 to 0.014 mg/L. Concentrations were highest in the north-west part of the Marine Survey Area (Figure 7.25). Concentrations rose to between 0.035 and 0.045 mg/L at 60 to 70 m depth.

In spring 2011, nitrate concentrations in the surface waters were highest near the coast, typically around 0.01 to 0.02 mg/L, but were very low (below 0.002 mg/L) further out to sea (Figure 7.25). Concentrations rose to between 0.05 and 0.06 mg/L at 50 to 60 m.

Nitrate content in the surface waters of the nearshore and offshore sections of the Marine Survey Area did not usually exceed the MAC for fisheries (Ref. 7.16).

**Nitrite**

Nitrite is present in the marine surface waters, being relatively evenly distributed to the thermocline in summer and winter but depleted at the surface during the spring and autumn phytoplankton blooms. Nitrite concentrations in the surface waters typically range from 1.5 to 4.5 µg/L but are 6 to 8 µg/L at around 50 to 75 m depth. Nitrites are absent in the deeper anaerobic (H₂S) zone.
In autumn 2010, nitrite concentrations in the surface waters were up to 6 µg/L. In spring 2011, nitrate concentrations in the surface waters were up to 5 µg/L, being higher near the coast. The maximum concentration was observed in the Anapa area. Nitrite content in the nearshore and offshore sections of the Marine Survey Area did not exceed the MAC of 80 µg/L for fisheries (Ref. 7.16).

**Figure 7.25 Spatial Distribution of Nitrate Concentrations in Surface Waters (Ref. 7.1)**

![Figure 7.25 Spatial Distribution of Nitrate Concentrations in Surface Waters](image)

a) Autumn 2010  

b) Spring 2011

**Ammonium Nitrogen**

Ammonium nitrogen concentrations are low in the aerobic surface waters, with concentrations of 0.002 to 0.036 mg/L. In the anaerobic zone, concentrations rise with depth up to 1.8 mg/L at 2,000 m. The seasonal patterns in ammonium nitrogen mirror those of nitrate, reflecting the influence of phytoplankton activity.

In autumn 2010, ammonium nitrogen concentrations in the surface waters ranged from 0.009 to 0.025 mg/L with an average value of 0.011 mg/L. The maximum concentration was recorded near Gelendzhik.

In spring 2011, ammonium nitrogen concentrations in the surface waters showed a similar pattern to nitrate, being highest (typically around 0.015 to 0.025 mg/L) near the coast in the vicinity of Gelendzhik and Anapa. In the seaward part of the Marine Survey Area, concentrations were lower, ranging from 0.005 to 0.010 mg/L. Ammonium nitrogen concentrations were highest at depth, being 0.20 to 0.35 mg/L in deep waters.

Ammonium nitrogen content in the nearshore and offshore sections of the Marine Survey Area did not exceed the MAC of 2.9 mg/L for fisheries (Ref. 7.16).
Total and Organic Nitrogen

There is limited information available regarding total and organic nitrogen concentrations in the Black Sea. Literature values indicate that total nitrogen concentrations in the Russian sector of the Black Sea range from 89.6 to 681 µg/L with an average value of 263 µg/L in the open seas. Organic nitrogen concentrations range from 76 to 669 µg/L with an average value of 243 µg/L. The total nitrogen predominantly comprises organic nitrogen.

In autumn 2010, total nitrogen concentrations ranged from 0.05 to 1.32 mg/L with an average value of 0.14 mg/L. The majority of the total nitrogen was organic nitrogen. Organic nitrogen concentrations were 0.015 to 1.066 mg/L with an average value of 0.114 mg/L. Concentrations were highest in the northwest of the Marine Survey Area.

In spring 2011, total nitrogen concentrations in surface waters were typically 0.2 to 0.25 mg/L but were up to 0.4 mg/L in the northwest of the Marine Survey Area. Concentrations increased with depth, being 1.4 to 1.5 mg/L at 2,000 m depth. Organic nitrogen concentrations were typically 0.2 mg/L but were over 0.3 mg/L in the northwest and east of the Marine Survey Area. Concentrations increased with depth up to 1.33 mg/L at 2,000 m depth.

7.4.5.10 Sea Water Contamination

Previous surveys in the Russian Sector of the Black Sea have identified the presence of contaminants in the sea water, including several organochlorine pesticides, petroleum hydrocarbons, phenols, and anionic surfactants. Additionally, elevated concentrations of heavy metals were locally detected, including copper, cadmium, lead, mercury and zinc. Contaminant concentrations varied spatially, but were typically higher near the coast (Ref. 7.1, 7.3).

Additional marine surveys (Ref. 7.1) were undertaken within the Marine Survey Area in 2010 and 2011 to further assess recent water quality in the nearshore and offshore areas. The results are summarised in Table 7.20 and 7.21. The sampling locations are shown in Figure 7.3.

Note –
1. The detection limit for the organochlorine pesticides varied between compounds:
   - α-hexachlorocyclohexane <0.0004 µg/L,
   - β-hexachlorocyclohexane <0.002 µg/L,
   - γ-hexachlorocyclohexane <0.0005 µg/L,
   - heptachlor <0.002 µg/L,
   - aldrin <0.01 µg/L,
   - 4,4-dichlorodiphenyltrichloroethane (DDT) <0.003 µg/L,
   - 4,4-dichlorodiphenyldichloroethylene (DDE) <0.002 µg/L,
   - 4,4-dichlorodiphenyldichloroethane (DDD) <0.003 µg/L.
2. Background concentrations of some heavy metals (e.g. iron, manganese) in sea water in the deeper anaerobic waters would be anticipated to be higher than in the aerobic surface waters due to redox processes. For some heavy metals it is considered that exceedance of MACs set for fisheries is more significant in the surface waters than exceedance at depth in the anaerobic hydrosulphuric zone. Therefore, only MAC exceedances in the surface waters are presented in the above table; there may be additional exceedances in the deeper waters.

Note –
1. The detection limit for the organochlorine pesticides varied between compounds:
a-hexachlorocyclohexane <0.0004 µg/L,
b-hexachlorocyclohexane <0.002 µg/L,
g-hexachlorocyclohexane <0.0005 µg/L,
heptachlor <0.002 µg/L,
aldrin <0.01 µg/L,
4,4-dichlorodiphenyltrichloroethane (DDT) <0.003 µg/L,
4,4-dichlorodiphenylethylene (DDE) <0.002 µg/L,
4,4-dichlorodiphenyldichloroethane (DDD) <0.003 µg/L.
2. Background concentrations of some heavy metals (e.g. iron, manganese) in sea water in the deeper anaerobic waters would be anticipated to be higher than in the aerobic surface waters due to redox processes. For some heavy metals it is considered that exceedance of MACs set for fisheries is more significant in the surface waters than exceedance at depth in the anaerobic hydrosulphuric zone. Therefore, only MAC exceedances in the surface waters are presented in the above table; there may be additional exceedances in the deeper waters.
Oil products were present in the majority of samples but have been detected at concentrations above MAC in only three samples in autumn 2010. Concentrations were highest near Gelendzhik (Figure 7.26). Oil products were detected but did not exceed the MAC in the coastal sample collected in summer 2011.

Anionic surfactants have been detected in the majority of the water samples. The only sample that exceeded the MAC for anionic surfactants was Station 14 at 1,000 m depth. Concentrations in the surface waters were generally low.

Phenols were detected in about half the water samples in 2010 but in a smaller proportion of samples in 2011. Concentrations were highest near Gelendzhik.

The single exceedance of the MAC for manganese in the surface waters was in a coastal station near Anapa. Manganese concentrations in the surface waters generally decreased with distance from the coast. Concentrations were higher, locally exceeding the MAC, at depth in the deep water area but this is likely to be due to natural processes. Iron exhibited a similar pattern.

Chromium concentrations were below MAC. Concentrations were highest near the coast and the in the seaward cyclonic rise; concentrations were lowest in the MBSC.

**Figure 7.26 Spatial Distribution of Oil Product Concentrations in Surface Waters (Ref. 7.1)**

a) Autumn 2010  b) Spring 2011

Lead concentrations exceeded the MAC value in a significant proportion of the samples, including surface waters. Lead concentrations were typically highest near the coast (Figure 7.27). Lead concentrations on average are at or slightly above the MAC value.
Copper concentrations exceeded the MAC value in a large proportion of the samples, including surface waters. Copper concentrations on average are at or slightly above the MAC value. Concentrations are highest in the southeast of the Marine Survey Area (Figure 7.28). Generally the measured copper concentrations are similar to reported background concentrations in the Black Sea. Zinc concentrations were all below the MAC value but showed a similar distribution pattern to copper in the surface waters.
Cadmium concentrations did not exceed the fisheries MAC and were in line with background concentrations in the Black Sea. Mercury concentrations did not exceed the fisheries MAC; concentrations were highest near the coast and in the area of cyclonic rise in the seaward area.

Nickel did not exceed the fishery MAC values in the autumn 2010 or spring 2011 surveys with concentrations typically being below detection limits except near the coast. However, in summer 2011, the concentration was 13.7 µg/L in the coastal sample, exceeding the MPC.

Concentrations of molybdenum were typically at or just above the MAC value. Concentrations were highest in the south and near Anapa. Generally the measured molybdenum concentrations were reported to be similar to background concentrations in the Black Sea.

Bacteriological testing was undertaken on two coastal samples collected in summer 2011. The results are consistent with relatively low levels of faecal contamination. Based on the limited testing, the waters meet the microbiological requirements of SanPIN 2.1.5.2582-10 (Ref. 7.17).

The eastern part of the Black Sea is less affected by eutrophication (increase in nutrients into the aquatic system) than the west due to the absence of major riverine inputs (Ref. 7.3).

The offshore Russian waters do not show evidence of significant pollution. Although some exceedances of fishery MACs by metals were measured, the majority of these can be attributed to natural background concentrations taking into account the natural chemical processes of the Black Sea. The coastal waters, particularly near Gelendzhik and Anapa, have elevated concentrations of contaminants present, including oil products, anionic surfactants, phenols and metals such as lead. Sources of contamination are likely to include port activities, runoff and discharges.

### 7.5 Geophysical Environment

#### 7.5.1 Tectonic Setting and Geology

##### 7.5.1.1 Tectonic Setting

The tectonic setting of the eastern Black Sea region is presented in Figure 7.29.

The Black Sea is a back-arc marginal extensional basin, which originated from the northward subduction of the Tethys Ocean beneath the southern margin of the Eurasian plate (Ref. 7.1).

The present day Black Sea basin was formed by the joining of two extensional basins, the Western Black Sea basin and the Eastern Black Sea basin, which have different tectonic histories and are different ages. The two basins are separated by the Mid-Black Sea high (Andrusov ridge and Archangelsky ridge). Further compressional tectonic processes led to the subsequent subsidence of the region (including western basin, eastern basin and separating ridge) to form the present day Black Sea basin (Ref. 7.1).

The Greater Caucasus is part of the Alpine-Himalayan orogenic system and is located between the Eurasian plate to the north and the African-Arabian plates to the south.

Global plate models and space geodetic measurements indicate that in the surrounding region, northward moving African and the Arabian plates collided with the Eurasian plate. From this collision, the Anatolian micro-plate moves westward with a rotation pole located approximately in the north of the Sinai Peninsula.

The Terrestrial Study Area is located in foothills, between the Greater Caucasus Main Range mountains and the Azov-Kuban lowland. Tectonically, the Terrestrial Study Area is part of the Greater Caucasus thrust belt, which extends east from the edge of the Tuapse trough (located in the Black Sea) inland to Indolo-Kuban foreland basin (Ref. 7.20). The north-western part of the Greater Caucasus’ fold belt is a ridge composed of Mesozoic and Palaeogenic rocks. The landscape has been developed through the erosion of the mountain range following tectonic faulting and folding during the Neogene, approximately 23 to 2.6 million years ago (Ref. 7.1).

The Marine Study Area is located in the Eastern Black Sea Basin.

The south-western flank of the Greater Caucasus thrust belt extends along the narrow shelf and upper part of the Black Sea’s continental shelf. Towards the north-west from Anapa, the Mesozoic and Palaeogenic rocks plunge sharply beneath the Oligocene to Quaternary sediments of the Kerch Strait.

The Tuapse depression (also known as the Tuapse Basin) was formed in the Oligocene by subduction beneath the Greater Caucasus. The depression is about 60 to 70 km wide, and is oriented northwest to southeast roughly parallel to the shore. The depression has a sharply asymmetric geometry, with a steep north-east slope and a gentle south-west slope.

The Shatsky Ridge is a massive raised crustal block that forms the north-eastern edge of the deep-water Eastern Black Sea depression. The Shatsky Ridge is oriented northwest to southeast and has very steep south-western and north-eastern slopes. The upper part of the elevation is covered by post-Maikopean deposits.

The Eastern Black Sea depression is the deepest part of the Marine Study Area. It is characterised by thick sedimentary sequences of Palaeogene and Holocene age. These sediments are underlain by Eocene chalk deposits over basement strata.

7.5.1.2 Terrestrial Geology

The underlying bedrock geology within the Terrestrial Study Area is characterised by terrigenous and carbonate Miocene and Pliocene rocks, including argillites and clays, conglomerates, limestones, dolomites, marls and sandstones (Ref. 7.1). Based on the geotechnical investigations, the majority of the near-surface strata in the Terrestrial Survey Area comprise marls interbedded with sandstone, limestones and clays (Ref. 7.21). These strata are more than 25 m thick in the Terrestrial Survey Area. The Miocene and Pliocene strata are underlain by folded Palaeozoic structures and Jurassic and Cretaceous monoclines. A map of the regional geology at the Study Area is presented in Figure 7.30.
The bedrock is exposed at the coast and locally in the valleys. The bedrock deposits are well to medium bedded (Ref. 7.22). The marl beds are up to 2 m thick. In the upper 5 m near the surface, the bedrock is weathered and has a low rock mass rating. At depth, the bedrock has a low to medium rock mass rating, with considerable lateral and vertical variation. At the shore, the bedrock bedding dips steeply towards the sea. The coastal ridge comprises an anticlinal structure; the folding is disrupted locally by faulting.

The bedrock deposits are overlain by a mantle of unconsolidated Quaternary deposits of variable thickness.

Overlying Quaternary deposits include a mantle of unconsolidated alluvial, colluvial, eluvial, fluvial, diluvial and coastal marine sediments of variable thickness ranging from a few metres to tens of metres. The general characteristics of Quaternary deposits encountered in the Terrestrial Survey Area are described below (Ref. 7.1):

- **Alluvial deposits** – Loose, unconsolidated (un-cemented) sediments, which have been eroded and/or reshaped by water and redeposited on land down gradient of their origin. Alluvial deposits are typically 1 to 5 m thick. Deposits are distributed along valley floors and are variable in composition (comprising sandy clay, limestones, marls and/or fragments of other types of weathered bedrock);

- **Colluvial deposits** – Loose unconsolidated variable sized sediments, ranging from silt to rock sized fragments. Deposits are typically located at the base of hill slopes, as a result of erosion and deposition by rain wash, sheetwash and/or slow downslope creep of sediments;

- **Eluvial deposits** – Soils derived from either the in-situ weathering of underlying bedrock or the weathering of bedrock combined with limited movement or accumulation of the soils due to gravitational creep on gently inclined slopes;

- **Fluvial deposits** – Fluvial soils are typically located on alluvial floodplains, river fans and valleys. They form on alluvial sediments and can be mixed in with flood surge deposits. Deposits include loam, silts and sandy clays to clayey sands;

- **Diluvial (flood) deposits** – Encountered mainly on the slopes of hills and at the base of coastal cliffs. Deposits comprise loose accumulation of angular rock fragments in a matrix of clay and sand, and typically range between 1 to 5 m thick; and

- **Coastal Marine Sediments** – Includes sandy beaches, and sand, gravel and boulders.

Soils are typically formed through the erosion and re-deposition of underlying bedrock deposits. The predominant soil forming bedrock material is weathered marl. Soils covering higher slopes and ridges are typically formed by the weathering or re-deposition of calcareous argillites and interbedded sandstones and siltstones. Soils encountered within river valley systems typically form from weathered calcareous marls, interbedded limestones, siltstones and shales. Deposits in the valley bottoms comprise variable gravel and sand deposits with occasional layers of clays and loam material interbedded in the coarser-grained material (Ref. 7.23).

The characteristics and distribution of soils across the Terrestrial Survey Area are described in further detail in **Chapter 8 Soils, Groundwater and Surface Water**.

7.5.1.3 Marine Geology

The geology in the nearshore and offshore sections of the Marine Study Area comprise both Upper Cretaceous and Palaeogene Flysch deposits. Upper Cretaceous flysch deposits comprise coarsely stratified bituminous marls inter-bedded with the bands of quartz-glaucgonite sandstones. The uppermost sequence of Cretaceous flysch deposits are typically dark clays, separated by sandstones and dense dark marls. Palaeogene flysch deposits comprise dense clays, dark coloured hard metamorphosed marls with some inter-bedded sandstone bands.

During the Neogene stage of Alpine orogeny the flysch deposits of both the Upper Cretaceous and Palaeogene were subject to intensive deformation and folding associated with this period of thrusting and faulting.

The marine sediments that overlie the bedrock vary in thickness from absent to several metres thick. The marine sediments are discussed further in Section 7.5.5.

7.5.2 Seismicity and Geohazards

The tectonic structure of the Black Sea basin is complex and the collision zone between the African and Eurasian plates, as well as movement around the various microplates, has created a zone which is prone to earthquakes. Significant earthquakes have affected several countries, including Russia, on the eastern side of the Black Sea tectonic basin.

The Greater Caucasus is a zone with active compression where thrust and strike-slip faulting associated with on-going earthquake activity has continued to the present time (Ref. 7.25). A seismically active zone is known in the Anapa region where the Crimean and Caucasus structures meet. This is manifested as a seismic belt from the southern foot of the Crimea to the Anapa region. In 1966, the Anapa earthquake (magnitude 5.8) occurred in this belt.

Seismic activity in the region typically has a potential to cause earthquakes of magnitude 5 to 6 on the Richter Scale (Ref. 7.1). Recent earthquakes in the area include a 4.9 magnitude earthquake centred in Varenkovskaya (located approximately 32 km northeast of Anapa) in 2012 and a 4.4 magnitude earthquake centred at Anapa in 2011.

Seismic studies (Ref. 7.5, 7.29, 7.30, 7.31, 7.32, 7.33, and 7.34) have been undertaken along the Pipeline route.

The Pipeline route crosses the southern branch of the Marfovsky Fault (Figure 7.31). This fault is active (Ref. 7.22). The fault is not a single lineament but instead comprises a fracture zone with northern and southern branches. The fault zone is approximately 200 m wide. The fault is well defined due to a distinct tectonic scarp. Current displacement values are estimated to be 0.2 m vertically and 1 m horizontally (Ref. 7.22). Slow (creep) fault displacement is estimated to be at a rate of 0.2 to 0.35 mm per year (Ref. 7.22).

As described in Chapter 5 Project Description, the fault will be crossed using traditional open-cut techniques. However, to minimise the effect of potential displacement from seismic activity, each pipeline will be laid in an enlarged trench backfilled with loose sand rather than the previously excavated soils. The combination of the wider trench and backfilling with loose
sand allows the pipelines to move in a lateral direction. This reduces the risk of movement on the Marfovsky Fault affecting pipeline integrity.

The pipeline route also crosses the Shingarsky Fault (Figure 7.32). This fault was mapped using geophysical survey methods (Ref. 7.21). The Shingarsky Fault comprises a fracture zone up to 50 m wide of weak and weathered rock. Based on local geomorphology and the overlying superficial deposits, this fault is considered to be inactive (Ref. 7.5). The Shingar River is aligned with the Shingarsky Fault; the weathered fracture zone of the fault is likely to have allowed preferential erosion along the line of the fault during flood events. The microtunnel route crosses the Shingarsky Fault.

The West Utrish Fault is a large regional tectonic fault associated with the structural zoning of the North West Caucasus (Ref. 7.22). It is inferred to have an east-west strike. The West Utrish Fault has not been identified within the Project Area (Ref. 7.22); it is interpreted to be parallel to the coast (probably on seaward side) and to be inactive in the Project Area.

Additional fracture zones (interpreted to be potential faults) have also been interpreted (Ref. 7.22, 7.27) from the seismic survey data and geohazard mapping. These may reflect conjugate faulting or jointing associated with past activity of the Shingarsky Fault.

Four fissure zones have been mapped along the coastal ridge (Ref. 7.22); these are shown on Figure 7.31. The fissure zones are up to 80 m wide. The fissure zones have been preferentially weathered and have a topographical expression. The fissure zones may have formed through local tectonic or gravity-induced ground movements. These may relate to the deep-seated rotational failure planes mapped along the coast or to conjugate jointing associated with past activity of the Shingarsky Fault.

Although the abyssal plain is predominantly flat / to gently inclined, hill and ravine features are locally present. Hills are typically formed by mud volcano activity and may be 1 to 30 m high, with basal diameters of 600 to 1,000 m wide. Mud volcanoes are formed by the expulsion of mud, rock fragments and fluids (especially methane) from depth. Recent turbidite flows occur in the vicinity of the mud volcanoes. No large mud volcanoes have been identified along the Pipeline route (Ref. 7.36). Ravines are typically associated with tectonic faults, none of which are considered to be active (Ref. 7.28). The ravines are generally asymmetric in shape, with one relatively steep slope (typically 10 to 20 m deep) and one comparatively flatter slope; although some symmetrically shaped gently inclined ravines are also encountered. Ravines are typically between 500 to 1,000 m in length (minimum of 200 and maximum of 4,500 m).

Natural gas seepage associated with the degradation of organic rich material may be encountered on the abyssal plain. In addition, features associated with natural gas seepages include blow outs of shallow gas reservoirs and gas plumes (Ref. 7.1).

The Russian continental slope is currently tectonically active, with fault movement impacting slope stability, sediment distribution and earthquakes. Tectonic activity reduces away from the coast from the Caucasus Mountains to the Tuapse depression (Ref. 7.5).

The north eastern Black Sea seismic source zone is characterized by low to moderate seismicity with the majority of events having a magnitude lower than 5 (Ref. 7.26, 7.30). The largest event recorded occurred in 1905 with a magnitude of MW 6.6 and focal depth of 38 km. The epicentre
was in the offshore Southern Black Sea at more than 300 km from the Anapa landfall. The event was associated with a tsunami.

No significant seismic events have been recorded within the Shatsky Ridge. Very rare earthquakes may be associated with small movements over rejuvenated faults penetrating the Quaternary layer. Faults occur in the Maikopean (Upper Palaeogene – Lower Neogene) clays on the shelf of the Kerch-Taman deflection and in the Tuapse deflection. These faults are associated with clay diapers and mud volcanoes. The faulting is predominantly oriented northwest-southeast.

Several of the earthquakes in the Black Sea region appear to have been associated with tsunami waves along the coast (Ref. 7.26).

Within the Marine Study Area, seismic studies (Ref. 7.5, 7.30, 7.31, 7.32, 7.33, 7.34, and 7.35) indicate that:

- Major active tectonic faulting does not cross the offshore pipeline route (Ref. 7.26, 7.30);
- Active faults were not observed on any of the sub-bottom profiles conducted along the pipeline routes (Ref. 7.29);
- No faults considered dangerous to pipeline integrity have been identified (Ref. 7.26) along the pipeline route in the marine Project Area;
- Sediment deformation associated with tectonic movement is most likely to impact very soft superficial clay deposits on the shelf and continental slopes; and
- Limited slope failure involving 2 to 3 m thick layers of sediment and movement of superficial sediments on the continental slope are anticipated as a result of an earthquake of with a return period of 1 in 475 years. Shallow failures of <2 to 3 m thick have been predicted for an earthquake of this recurrence period.

7.5.3 Terrestrial Geomorphology

The landscape and geomorphology of the Terrestrial Survey Area often dictates the vegetation cover. There are two distinct landscape terrains and associated vegetation cover:

- Plain (gently sloping plateau) and hilly terrain covered by a complex of arid woodlands; and
- Hilly submontane terrain, covered by mixed oak, pine, juniper forests and arid woodlands.

A map of the local geomorphology of the Terrestrial Survey Area is presented in Figure 7.32.

An example of the gently rolling hills encountered in the Terrestrial Survey Area showing a combination of agricultural fields (vineyards) and woodlands is presented below in Figure 7.33. The ecological habitats are described in **Chapter 11 Terrestrial Ecology.**

**Figure 7.33 Typical Undulating Landscape of Terrestrial Landfall Section (Ref. 7.1)**

The landfall facilities will be located approximately 1.4 km inland north-east of a steep coastal cliff (approximately 150 m high where crossed by the Pipeline route), on a high level gently sloping ‘plateau’. The surface of the plateau is typically gently undulating; however, in places the plateau has been eroded by fluvial processes to form steeply sloped river valleys, up to 150 m deep. Erosion features include hollows, incisions and gullies, which are often steeply sided and are up to 5 to 10 m deep (Ref. 7.1).

7.5.3.1 **Fluvial Geomorphology**

The fluvial erosion features are typically formed by a process of surface washout and flooding by the ephemeral\(^7\) watercourses. This causes soil sediments and underlying rock to be removed and transported down gradient to form landslide and talus (debris) slope deposits (Figure 7.34).

---

\(^7\) An ephemeral waterbody is a wetland, spring, stream, river, pond or lake that only exists for a short period following rainfall or snowmelt.
Chapter 7 Physical and Geophysical Environment

The spring-summer period is characterised by large storms, which often lead to further soil erosion and subsequent aggradation and accumulation of sediments on lower slopes.

Figure 7.34 Erosion Features Associated with the Watercourse in the Graphova Gap (Ref 7.1)

Valley and water channel features associated with ephemeral watercourses and their tributary gullies are also present across the Terrestrial Survey Area. Further details on the watercourses and groundwater within the Terrestrial Survey Area are provided in Chapter 8 Soil, Groundwater and Surface Water.

Watercourses in the Terrestrial Survey Area include the Shingar River and an unnamed tributary of the Sukko River (Graphova Gap). Both rivers flow approximately north to south crossing the Project Area, with the route of the proposed pipeline crossing them at approximately right angles. The Pipeline will cross the Graphova Gap by open-cut methods and will be microtunnelled beneath the Shingar River.

In the vicinity of where the proposed pipeline route crosses the Shingar River, the river valley is asymmetrical in shape, and the base of the valley is approximately 55 to 65 m wide. The slope on the eastern side of the valley is approximately 15 to 25°, 30 to 50 m in length and forested. The western side of the valley has been altered due to the construction of the coastal access road. The slope is stepped, with the road constructed on a cut and fill bench approximately 13 to 15 m wide. The western slope is very steep in places (up to 25 to 35°), largely treeless and is subject to slope erosional processes. The Shingar River is typically 1.5 to 2.5 m wide in the
vicinity of the pipeline crossing and is located approximately 1.0 to 2.0 m below the adjacent floodplain terrace at the base of the river valley (Ref. 7.1).

Approximately 1.5 km east of the Shingar River, the pipeline route crosses the unnamed tributary of the Sukko River at the Graphova Gap. At this location, the Graphova Gap is asymmetrical in shape, and the base of the valley is approximately 80 to 100 m wide. Valley slopes are 30 to 40 m high and steeply sloped at 20 to 30°. In general, the slopes of the valley are forested; however, there are localised areas of slope that are devoid of vegetation (due to removal associated with economic activity within the valley) that have exposed bedrock and associated erosion processes in the valley sides. On the lower slopes of the valley and associated floodplain are several man-made embankment and ditch features (typically <3.0 m wide and 0.5 to 1.3 m deep) constructed as protection measures to help control storm water flow into valley of the unnamed tributary (Ref. 7.1).

The steep scarp slopes along the Graphova Gap and the Shingar River are subject to fluvial erosion. Erosional scour of 3 m can be expected as well as undercutting and collapse of the banks (Ref. 7.22).

Russia’s Black Sea coastal region is known to experience periodic mudflows. The sudden formation of mudflow and mudrock flows is possible in the valleys of the Shingar River and the Graphova Gap and their tributary gullies. Retrospective analysis and reports from locals indicate that mudflows occur once every several (5 to 7) years, each time causing large damage (Ref. 7.5). Mudflows are typically triggered by intense rainfall events or prolonged rain.

7.5.3.2 Coastal Morphology

The coastal cliff is approximately 150 m high in the landfall area of the pipeline crossing and generally convex to a stepped-in profile. The average steepness of the slope is 15° to 25°; however, in places the slope can increase to 40° to 70° (Ref. 7.22). The lower 30 to 50 m of the cliff is typically covered by a talus apron of eroded and abraded loose cliff sediments, with active cliff erosion and rockfall processes having been observed to a height of 120 to 140 m above sea level (Ref. 7.1). Vegetation within the coastal zone is limited to sparse plant cover on the cliffs, rock outcrops and scree slopes associated with the coastal cliffs. At the shore, the beach deposits comprise varied and often poorly sorted sediments ranging from boulders and pebbles to sands and silts. The width of the beach at the foot of the cliff is generally 5 to 15 m wide.

Erosional processes associated with the coastal cliff zone include landsliding and slumping of the coastal cliff and erosion of interbeds of softer sediments exposed in the cliff face (Figure 7.35). Erosion processes along the coastal cliff typically occur as a result of abrasion and weakening of the cliff face from wave action, gravity slumping or tectonic processes (earthquakes or movement along fault planes).

The relatively narrow beach provides limited protection to the base of the cliffs against direct wave action. Wave attack also assists in the removal of material at the toe of the cliffs resulting in periodic landsliding and slumping events (Figure 7.35). In the Terrestrial Survey Area, cliff recession rates are typically 3 to 10 cm per year and the average shoreline recession is
calculated to be 41.6 m per century. The microtunnelling approach to the shore crossing (Chapter 5 Project Description) mitigates the risks associated with coastal erosion.

Figure 7.35 Examples of Typical Coastal Abrasion Features Associated with Coastal Cliff Landsliding and Erosion of Softer Sediments on the Cliff Face (Ref. 7.1)

There are large-scale rotational slump features along the coast (Ref. 7.22), where material is moving downhill under gravity. These are up to 160 m long and 700 m wide, with hanging walls of up to 15 m. These are regarded as active features. Their rotational failure planes are potentially deep-seated.

A relatively recent landslip has occurred approximately 2 km northwest of the Project Area (Ref. 7.22). This feature has collapsed into the sea causing a local inflection of the coastline. The landslip is about 500 m wide. The toe of the slope extends 60 m into the sea. This landslip is assumed to have failed in a rotational manner. The failure plane may extend below sea level.

Within the coastal area of the Abrau Peninsula located to the south of the Terrestrial Study Area are four landslides, inferred to be earthquake induced, with areas of approximately 3 to 4 km² (Ref. 7.1). The heads of the earthquake induced landslides are located on land but the features extend a further 2.0 to 2.5 km out to sea across the coastal shelf.

### 7.5.4 Marine Geomorphology

The geometry of the sea floor in the Russian Sector of the Black Sea has been mapped using a multi-beam echosounder (SSC FSUGE Yuzhmorgeologiya, 1996-1997). The bathymetry data has been used to assess the marine geomorphology (Ref. 7.5).

From east to west the route of the pipeline crosses three main geomorphological zones through the Russian Sector of the Black Sea: the continental shelf, the eastern continental slope and the abyssal plain. The geomorphological zones are shown in Figure 7.36.

The geomorphology of each zone is discussed in the following sections:
7.5.4.1 Continental Shelf

The Russian continental shelf is gently inclined towards the west at 0.4° and is subdivided into two zones:

- Coastal slope - extending from coastline to 50 m below sea level (mbsl); and
- Coastal platform - extending from 50 mbsl to 100 mbsl.

Sediment cover on the Russian Shelf is typically between 5 to 12 m thick and overlays folded bedrock of carbonate flysch.
The western extent of the Russian continental shelf is bound by a major fault scarp which crosses the Black Sea between Anapa and Gelendzhik, which marks the start of the Continental slope.

Evidence of landslides on the continental shelf has been identified near the Utrish Cape. Elsewhere on the shelf, limited evidence of landsliding has been found. Mudslides in response to earthquakes are anticipated in the base of the continental shelf. Sensitive deposits include the weak silts found close to the brow of the shelf.

7.5.4.2 Continental Slope

Beyond 100 m water depth, the continental slope starts dipping steeply to the west towards the abyssal plain. The transition from the continental shelf to the continental slope is marked by a distinct escarpment.

The shape of the continental slope off Anapa is controlled by bedrock, comprised primarily of the Mesozoic and Neogene Flysch which is also observed along the present coast. Bedrock is at or close to the surface in parallel ridges aligned along the slope. The presence of bedrock at or near the sea floor is the main reason why the continental slope is steep (Ref. 7.5).

In general, the gradient of the continental slope decreases towards the base of the slope (at 1,900 m depth). Gradients can exceed 30° at the shelf break and the continental slope typically varies from 27° at the top to 5° at the bottom.

The geomorphology of the continental slope is characterised by highly dissected dendritic drainage patterns of ridges and canyons. This morphology is the result of cycles of erosion, which caused retreat of the slope and the development of a random network of valleys (Ref. 7.5). The channels are partially filled with mud flow deposits.

The Anapa Canyon is the predominant geomorphic feature on the continental slope in the Study Area (Ref. 7.26). The Anapa Canyon cuts through sediments from the Pleistocene Kuban River delta. The main canyon corresponds with the sediment transport path from the Sea of Azov to the Black Sea and is a relic feature of the estuaries of the Don and Kuban rivers. As the Kuban fan slopes southeast towards the abyssal plain, the toe of the continental slope is found at a progressively lower elevation moving towards the southeast. The canyon itself is an integral part of the submarine delta formed from the Kuban and Don Rivers. The canyon runs parallel to the Russian Black Sea coast from a depth of 200 m to approximately 1,500 m. A further two stable canyons have been identified running down the continental slope and merging with the Anapa canyon at its mouth. The northern slope of the Anapa canyon is steep and itself incised by smaller canyons. The floor of the canyon is further incised by a trough. The canyon is shown in Figure 7.37. The interpreted geomorphology where the Pipeline route crosses the canyon is shown in Figure 7.38.

The upper slope is shown in Figure 7.39. The gullied terrain has rugged topography. The gullies are dendritic (Figure 7.40). The sidescan sonar images (Figure 7.41) suggest the present of coarse sediment in the upslope part of the dendritic gullies (Ref. 7.36). Locally bedrock is exposed in the gully walls (Figure 7.42). Gully system heads form a characteristic ‘cauliflower’ shape (Ref. 7.36). Upslope, most gullies gradually shallow and die out just below the continental
shelf edge. However, some terminate in a distinct headwall scarp that suggests that gullies can propagate upslope by headward erosion (Ref. 7.36).

Downslope, the broad valleys have steep downslope gradients (8 to 10°) but relatively smooth floors. The valley flows are characterised by sediment waves oriented across the slope. There are frequent large boulders (Figure 7.43) covered only by a thin intermittent sediment drape (Ref. 7.29).

Small carbonate mounds related to fluid seepage can be identified at a few locations along the Russian shelf break at depths between 110 and 140 m (Ref. 7.36); a small number are in relatively close proximity to the Pipeline route (Figure 7.44). These carbonate mounds are usually associated with gas seeps. Gas seeps have been documented in the Black Sea. Some of these seeps are associated with flare reaching up to 500 m from the sea floor, although the majority are between 50 and 130 m high (Ref. 7.36). The majority of gas seeps occur along the shelf break and are often associated with faulting. The principal biogeochemical process forming the concretionary carbonates at the seeps is the sulphate-dependent anaerobic oxidation of methane. This can create reef structures several metres in height. These structures release methane bubbles.

The lower Russian continental slope (Figure 7.45), extending from 1,500 m to about 2,000 m, is generally relatively smooth with a decreasing gradient. The exception to this smooth slope is a marked incision where the Anapa Canyon cuts across the slope, creating a series of scarps at about 1,650 m water depth.

Figure 7.45 Overview of Sidescan Sonar Data for Lower Russian Slope (Location F) (Ref. 7.36)
The Anapa Canyon and associated channel is covered by soft sediment, suggesting it is not an active conduit for turbidity currents at the present time. The sedimentary drape is about 1 to 2 m thick, suggesting limited turbidity current activity during the last few thousand years.

The Anapa Canyon appears to continue as a stream of fine sediment extending to the abyssal plain. The regional data shows the channel extends beyond the limits of the continental slope and that sediments from the canyon affect the morphology of the Holocene portion of the Kuban Delta. Recent sediment may be creeping slowly under gravity down the slope in this area of the continental rise.

Downslope from the Anapa Canyon, the slope is characterised by landslide scars and depositional detritus lobes. These are all low relief features with slide scarps typically only a few metres high (Ref. 7.36). Figure 7.46 shows a landslide scarp on the lower Russian slope. This scarp is 2 to 4 m high and may represent a palaeocoastal feature. Figure 7.47 shows debris lobe features on the lower Russian slope. The lobe edges exhibit typical frond-like patterns.

**Figure 7.46** Sidescan Sonar Image of Landslide Scarp on Lower Russian Slope (Ref. 7.36)

The seabed in the continental slope area is generally characterised by unstable sediments and is often subject to dynamic processes, including gravity flows of sediment towards the abyssal plain (e.g. submarine slumps and associated “turbidite” flows). Instability of the seabed sediment is often triggered by seismic activity and, to a lesser extent, by the sedimentation process itself.
Sediment cover typically comprises very soft clays with some shells, overlaying an unconformity of debris flow deposits and layers of stiff clays and fine sands. The thickness of sediments on the slope is variable, from no sediments present to >20 m of sediment cover. The lower part of the continental slope was denuded in the Pleistocene. There are locally outcrops of basement rocks.

The Anapa canyon has been identified as a key engineering constraint on the continental slope. As described in Chapter 4 Analysis of Alternatives, in order to spread the risk associated with the seabed instability on the continental slope, the pipeline route is split such that two pipelines are to be laid down in each of the two stable canyons, with the four pipelines converging again at the mouth of the Anapa canyon.

Landslide activity is most intense in the upper part of the continental slope due to the steeper slope angle. As described in Chapter 4 Analysis of Alternatives, the alignment of the pipeline route has been selected following geohazard mapping; the pipeline route is designed to utilise areas with comparatively stable submarine topography as far as is possible.

The pipeline crossing relative to the Anapa Canyon is illustrated in Figures 7.48 and 7.49.
Figure 7.48 Anapa Canyon Crossing

Figure 7.49 Continental Slope Crossing
7.5.4.3 Abyssal Plain

The abyssal plain lies at the base of the continental slope and gently slopes to the west to a maximum depth of approximately 2,200 m. From the base of the continental slope, the pipeline route extends across the abyssal plain towards the border of the Russian EEZ with the Turkish EEZ. There is no clear slope break marking the boundary between the lower continental slope and the abyssal plain.

Figure 7.50 shows the typical conditions on the abyssal plain. The sea floor is essentially smooth and almost featureless across the entire area. There are lineations, predominantly trending west northwest approximately parallel to the contours. The pattern of lineations suggests that they are related to the inflow of dense saline water from the Mediterranean into the Black Sea (Ref. 7.36). These features have negligible bathymetric expression, suggesting that they are relatively old features buried by later sedimentation (Ref. 7.36). The lack of topographic relief on the lineations suggests that the process that created them is not currently active (Ref. 7.36). These lineations are associated with irregular marks, which are interpreted to be tool marks due to objects such as trees carried in bottom currents gouging the sea floor.

Figure 7.50 Sidescan Sonar Image of Abyssal Plain Showing Lineations and Tool Marks (Ref. 7.36)

The seabed within the abyssal plain is typically characterised by horizontal layers of carbonate rich silt and / or clay sized sediments.
7.5.5 Marine Sediments

This section presents a description of the sediment transport processes associated with the marine environment and the characteristics of sediments encountered in the nearshore and offshore sections of the Marine Study Area. Further discussion of sediments in the context of marine ecological receptors are presented in Chapter 12 Marine Ecology.

7.5.5.1 Sediment Transport

The main sedimentary processes in the Black Sea are associated with the deep-sea fans located off the major rivers, with downslope sediment transport by turbidity currents through canyon systems, with landslides on the continental margins and with the development of mud volcanoes.

Sediment transport processes within the Black Sea are presented below in Figure 7.51. In the offshore section of the Marine Study Area, a north westward drift is evident, while in the nearshore section of the Marine Study Area, the drift is easterly. In the Marine Study Area (nearshore section), littoral drift of eroded sediment occurs in a south-easterly direction with a net drift rate of 19,000 m³/year (Ref. 7.1).

The majority of the seabed's surface is formed by Quaternary sediments. Due to the absence of major rivers in the coastal area, there is currently minor mass sediment transportation onto the shelf (Ref. 7.26). The main sources of sediment for the Anapa shelf are the Don and Kuban Rivers, which currently discharge through the Kerch Strait from the Sea of Azov (Figure 7.51). Secondary sources are the small rivers flowing from the southern slopes of the Greater Caucasus. Autumn and spring river surges may initiate submarine debris flows locally. High point sources of sediment can be introduced locally onto the shelf by large collapses of the coastal hills (Ref. 7.26). Additionally, a significant proportion of the sediment is of biogenic origin, forming within the marine environment.

The coastal processes where the pipeline route crosses the shore are predominantly represented by abrasion, sometimes complicated with rock falls and rock slides (Ref. 7.1). There is an accumulative relief zone in the coastal waters up to about 30 m water depth (Ref. 7.1) where wave activity transports sediments as is evidenced by the development of ripple marks.

The shelf in the Study Area comprises an abrasion-aggradation plain. Sediment transport at the shelf break and on the continental slope is predominantly due to mass wasting, including landsliding and density currents. On the Russian margin sediment transport via turbidity currents and debris flows was common during the last glacial period, but has been much reduced during the last 9,000 years (Ref. 7.36). Sediment creep has also been observed on the continental slope (Ref. 7.1).

3. West Caucasian Zone (Kudepsta River - Anapa)
4. Taman - Kerch Zone (Anapa - Feodosia)
5. South Crimean Zone (Feodosia - Balaklava)

Route of Proposed Pipeline
The MBSC may not have the capacity to initiate sediment motion on the seabed, but will influence a) the fallout patterns of fine suspended sediments entering the area and b) the residual trajectory of sediment suspended in the nearshore area by wave action.

Mud flows along the sea bed are characteristic of the south-eastern part of the Marine Study Area. They are common on the continental slope and the abyssal plain. These mud flows are fastest close to the sea bed, with maximum values of around 3 m/s but more typical values are less than 0.15 m/s.

Seismicity in the region is directly related to sediment transport processes:

- At the shelf break, deposits that have slowly accumulated over time can be ‘shocked’ into motion as sediment-gravity flows (liquefaction). Slumps occur, some on a very large scale, which may turn into turbidity currents which, through long periods of activity, carve the canyons that are found on the steep slope areas. This is an important process by which, over geological time, shelf sediments are transferred to abyssal depths;

- Fault movement below deep recent sedimentary deposits can cause bed surface features such as fault-aligned ridges, and mud volcanoes (faults triggering gas release). Faults also often control the alignment of major features (canyons, scarp slopes); and

- Fault movements can cause tsunamis, which produce sediment transport in littoral zones.

### 7.5.5.2 Sediment Composition

Typically the sediments of the Marine Survey Area (nearshore section) comprise a mix of stones, gravels and sands. The sands typically have a bulk density of 1.6 to 2.0 g/cm³ and a porosity of 23 to 25% (Ref. 7.1). Bedrock outcrops locally in the shallow waters. Additional sediment type data were collected during the 2013 marine survey (Ref. 7.8). Photographs of the sea bed taken during the survey are presented in Figure 7.52. Table 7.22 presents the sediment type of sampling locations based on the classification proposed by Folk (Ref. 7.41), which groups sediment grains into mud, sand and gravel on the basis of their diameter. The relative proportion of the sediment grains in the three categories is then used to describe the sediment.

Coastal sample locations were dominated by rock and sand deposits. Continental shelf locations dominated by mud with a limited number of samples containing sand and gravel grains. The continental slope samples were all classified as mud.

In the fans of the Kuban and Don Rivers on the continental slope, contemporary and Upper Holocene (Nymph) sands are also occasionally encountered.

There are clays and clay loams in the lower strata of the Quaternary section, which locally intersect with the shelf’s brow and the upper part of the continental slope, and also the lower part of the shelf.

The reported thickness of the clay and silt sediments in the Caucasian shelf reaches 10 m. In the Taman zone of the shelf the silts are 20 m or more thick. The clays are grey and dark-grey, silty and calciferous. The bulk density ranges from is 1.39 to 2.02 g/cm\(^3\). The porosity is

\(^8\) Based on Folk Classification (Ref. 7.41).
typically around 65% and the natural moisture content of the shelf muds ranges from 31 to 117% (Ref. 7.1). The typical composition of the clay sediments is summarised in Table 7.23.

Within the continental slope and abyssal plain unconsolidated water-saturated organic silts dominate. The thickness of the sediments on the slope is variable from no sediments present to several metres of sediment cover. The thickness of these sediments penetrated by the sampling is 6 m. The sediments in the deep abyssal plain typically have a high rate of sedimentation in the eastern Black Sea of between 0.2 – 0.4 m per thousand years (Ref. 7.5).

The variations in sea level over the history of the Black Sea (Section 7.4.4) are reflected in the marine sediment profile on the continental slope and abyssal plain (Ref. 7.36). In summary the most recent pelagic sediment layers in the Black Sea can be divided into:

- Unit I, the upper horizon approximately 30 cm thick, is a micro-laminated sediment, rich in plankton derived carbonates (coccoliths), with relatively low levels of organic carbon. This unit was deposited in oxygen depleted bottom waters;
• Unit II sediment (ca. 30 to 70 cm below the surface) is a micro-laminated sapropel deposited under anoxic marine conditions between approximately 2,700 and 7,700 years ago in waters deeper than 200 m. The onset of Unit II is characterized by the occurrence of thinly laminated layers rich in aragonite crystals and by a sharp increase in Total Organic Carbon;

• Transitional unit, marking the transition from lacustrine to marine conditions. This unit varies across the basin; and

• Unit III sediment, below approximately 70 cm, is older than 7,000 years and was deposited when the Black Sea was an oxic freshwater lake, and are characterised by mix of organic-poor clays and silts. Unit III sediments have organic contents <1%.

Above Unit I sediments lies a discrete proto-white lamina layer (about 2 cm thick), and above this lies a discrete benthic flocculant layer, also known as flocs or as the "fluff layer"; also about two cm thick. The flocculant layer has been observed to be largely composed of lithogenic material derived from the surrounding rivers (47%), carbonates derived from coccoliths (31%) with the remains of diatom and silicoflagellate blooms (7%) and particulate organic carbon, e.g. faecal pellets (6%). The proto-white laminae layer is composed of coccoliths (46%), lithogenic material (33%), the remains of diatom and silicoflagellate blooms (4%) and particulate organic carbon (7%).

The transition from the continental slope to the abyssal plain is typically characterised by a smooth transition in sediment geology, with the sediments of the abyssal plain being characterised by a higher mineral composition.

The surface horizon of the silts (Unit I) alternates between terrigenous aleuropelite silts with a thickness up to 5 to 7 cm and coccolith-sapropel pairs with a thickness ranging from 1 to 3 mm up to 2 to 3 cm (Ref. 7.1). These are also known as "turbidite" deposits. The layer of sapropel silt contains up to 20% organic carbon. The turbidite deposits are green-grey and dark grey and range from indistinctly stratified to finely layered. The sediment is viscous at the surface and soft plastic at depth. There is a characteristic hydrogen sulphide odour.

The silts often include inclusions of hydrotroilite, coccolith ooze, sapropel, and shell and plant detritus. The latter are usually sulphidised with micro-crystals of pyrite. Gas is present as bubbles and is also evident through sediment bulking. Again, there is a characteristic hydrogen sulphide odour. The typical composition of the silts is summarised in Table 7.24.

The majority of the deep water sediments are clays and silts. There is a regular compacting process of the silts with depth in the sediment profile. In the depth interval 0 to 0.1 m from the seabed, the silts are viscous and viscous-plastic; with depth the sediments are compacted, gradually becoming soft-plastic (Ref. 7.1).

---

Sapropel (organic-rich sediment) is produced when high levels of surface water productivity deposit organic matter into oxygen depleted bottom waters where the organic matter cannot be consumed.

The organic-rich sapropel and coccolith horizons are described as micro-layered jelly-like viscous sediments. Carbonate concentrations range between 1 and 57%. Organic matter content ranges from 4 to 36%.

The geotechnical properties of the silt depend on the degree of compaction, which, in turn, is related to the depth of the sediments. Sediment density increases with depth in the sediment profile. The viscosity coefficient of the sediments also decreases with depth. The bulk density of the abyssal plain deposits ranges from about 1.3 g/cm³ at the sea bed to about 1.5 g/cm³ at 50 cm depth. Moisture content also varies with lithology and depth. The natural moisture content of the abyssal plain sediments ranges from about 350% at the sea bed to about 125% at 50 cm depth. Sapropel sediments often have particularly high moisture contents, often exceeding 400% and sometimes reaching 550 to 600%.

Gas saturation of the sediments predominantly occurs in the silt deposits. Sources of gases may be migration flow of hydrocarbons from deeper parts of the section (particularly in the Taman Shelf), the gas draining from gas hydrate formations, or the build-up of diagenetic gases due to an excess of organic matter along buried palaeo shore lines (particularly along the shelf between Novorossiysk Bay to Sochi). Carbonate mounds, which are likely to be associated with gas seeps, have been locally identified near the shelf break.
Gas hydrates are commonly present in water depths below about 620 m although occasionally they have been identified in shallower waters (Ref. 7.36).

The concentration of gases (primarily methane) in the sediments is variable, ranging from 0.0107 to 7.1169 cm$^3$/kg with a typical local background value of 0.0285 cm$^3$/kg. With depth, the gas content rises by a factor of 1.5 to 2.5 but concentrations can be locally anomalously high, with concentrations being orders of magnitude higher than typical background values.

### 7.5.5.3 Sediment Quality

A known feature of the Black Sea basin is the presence of hydrogen sulphide (H$_2$S). The widespread presence of H$_2$S at depths over around 100 m is controlled by the redox environment. The shelf sediments are typically oxidised whereas the slope sediments are typically poorly reductive (Eh values -100 to +50 mV) but locally poorly oxidising (Eh values +50 to +300 mV); the latter are thought to be due to the influence of landslides and sediment wash. The sediments on the abyssal plain and in the fan of the Kuban and Don Rivers are highly reducing (Eh <-300 mV).

Contemporary Black Sea sediments together with their significant content of organic matter are characterised by high values of concentrations of sulphur and its reduced forms. The main form of accumulation of reduced sulphur in these sediments is pyrite (FeS$_2$). Pyrite is formed in the process of the sediments’ diagenesis from hydrotroilite (FeS$\cdot$H$_2$O) under its reaction with molecular sulphur.

In deep-water sediments, around 90% of the aggregate amount of reduced sulphur is present in the form of pyrite, which sometimes forms microconcretions (Ref. 7.1). In the silts on the continental slope, where there is an intense sulphate reduction process, there is an upper layer with a significant amount of hydrotroilite and free hydrogen sulphide. The latter’s content in the slopes’ silts reaches 100 mg/kg, while in deep-water sediments it is usually 3 to 5 mg/L. In the majority of sediments, the molecular-sulphur content is 200 to 300 mg/kg, or 6 to 8% of the aggregate content of sulphur compounds.

The pH of the continental slope sediments ranges from 6.98 to 8.12 with an average value of 7.54. The pH of the abyssal plain sediments is relatively even, ranging from 7.43 to 7.77 with an average value of 7.57.

Previous surveys in the area have identified the presence of contaminants in the marine sediments. Contaminants previously identified include petroleum hydrocarbons, phenols, anionic surfactants and heavy metals. Concentrations were typically highest near the coast, particularly in the vicinity of the main towns.

In addition, some heavy metals (e.g. iron, manganese) are naturally present in relatively high concentrations in the marine sediments in deep waters owing to the prevailing redox environment.

The level of sea bed pollution depends on many factors. These are mainly the lithological type of the deposit, particle sizes, the depth of the sea, the properties of the polluting substances (pollutants) and the level of their arrival from the coast, hydrological conditions, the system of currents, etc.
For the Caucasian coast of the Black Sea, which has a narrow shelf, pollutants in suspension are carried beyond the shelf, to the foot of the slope, where, as a rule, their greatest concentrations occur. In the shallow water of the coastal zone the highest concentration of terrigenous material is found. In this zone there is a greater degree of disturbance of sediment and a greater amount of oxidation taking place. This results in a more intensive self-purification of the sediment; these factors become weaker with distance from the shore.

Sediment sampling was undertaken in the 2010, 2011 and 2013 surveys (Ref. 7.1, 7.8) to assess concentrations of potential pollutants; the results are summarised in Table 7.25 (2010 and 2011 samples), Table 7.26 (2013 grab samples) and Table 7.27 (2013 sediment cores). In the absence of appropriate Russian standards for the assessment of marine sediments, international standards for contaminated sediments (target values of the “Dutch List”) (Ref. 7.18) were used to benchmark the quality of marine sediments. The values selected are referred to here as adopted marine sediment standards (AMSS).

Elevated phenol concentrations were identified in the majority of the samples. Concentrations of phenol were typically higher in the deep water samples compared with those from the nearshore environment. The elevated phenols may be derived from anthropogenic sources or may also be associated with natural organic matter in the sediment.

Anionic surfactants were detected in every sediment sample. Concentrations were typically higher in the deep water samples compared with those from the nearshore environment; concentrations were observed to rise with distance from the shore. The anionic surfactants are likely to be derived from anthropogenic sources.

Petroleum concentrations did not exceed the AMSS in the coastal sediment samples. Petroleum concentrations exceeded the AMSS in three out of six samples from the continental shelf and in two out of eight deep water samples. The elevated concentrations of petroleum may be derived from anthropogenic sources or may also be associated with natural organic matter in the sediment or natural hydrocarbons (oil and gas) beneath the Black Sea.

Whilst heavy metals have been detected in the marine sediments and locally exceed the AMSS, the results should be reviewed in the context of the natural geochemical setting. Organic silts and clays in reducing conditions might be expected to naturally have some heavy metals present - e.g. iron is naturally present in the form of pyrite and troilite. The sediment quality data should be viewed in this context. Metal concentrations were typically higher in the shelf and deep water samples than in the coastal samples. This is likely to reflect the change in sediment lithology and redox environment with increasing water depth and distance from the shore.

Continued...
Copper concentrations exceeded the AMSS in six out of eight deep water samples. Nickel concentrations exceeded the AMSS in two out of eight deep water samples. Although these samples had concentrations that were elevated above the AMSS, the measured concentrations are within the typical range for Black Sea sediments and thus do not necessarily indicate anthropogenic pollution. Heavy metal concentrations were typically higher in the Gelendzhik / Anapa region of the shelf and slope than in the rest of the Marine Survey Area.

From the 2013 sediment analyses petroleum products were the only parameter to exceed the AMSS in the grab samples (Ref. 7.8). The AMSS was exceeded at 6 out of 25 locations on the continental shelf with no exceedances from coastal or continental slope samples.

Similar to the 2010 and 2011 surveys, parameter concentrations increased with increasing water depth with the highest concentrations recorded in the continental shelf and continental slope samples with the exception of arsenic, which showed the highest concentration in coastal samples.

Concentrations of petroleum products were again the only parameter to exceed the AMSS in the core samples from proposed areas of dredging and seabed intervention. Exceedances occurred in 1 of 6 samples from the coastal samples in the proposed dredging area (location 17, top half of core = 150 mg/kg) and 1 of 8 samples from the seabed intervention areas on the continental shelf (location 38, top half of core = 54 mg/kg).
7.6 Conclusion

This chapter has provided a description of the physical and geophysical environment associated with the Project. Further, detailed baseline studies have been undertaken as part of each of the assessments contained within Chapters 8 to 18 which follow.

8 Soils, Groundwater and Surface Water

8.1 Introduction

This chapter presents the baseline characteristics of terrestrial soils, surface water and groundwater regimes within the terrestrial part of the landfall section of the South Stream Offshore Pipeline – Russian Sector (also referred to as ‘the Project’). It describes the impacts that the Construction and Pre-Commissioning Phase, Operational Phase (including Commissioning Phase and Full Operational Phase), and Decommissioning Phase of the Project may have on these environments. It also identifies mitigation measures required in order to remove and/or minimise potentially adverse impacts to the environment.

The environmental attributes of the terrestrial part of the landfall section discussed in this chapter comprise:

- Soils;
- Groundwater; and
- Surface water.

Impacts to soils are assessed because vegetation will be cleared and topsoil removed during construction which increases the potential for soil erosion by wind and by surface runoff. There is also the potential to encounter existing soil contamination associated with past land use or for new contamination to occur through accidental leaks or spills, which could result in impact on soils and mobilisation of soil contamination into groundwater or surface water. In addition, the stockpiling of topsoil and subsequent re-profiling may result in change to the soil structure.

Impacts to groundwater and to surface water are assessed as there is the potential for water quality and quantity to be affected. For example, elevated levels of suspended solids may occur in runoff during construction or accidental leaks or spills may occur.

Where possible, the physical and chemical characteristics of the terrestrial soils and groundwater regime that are described in this chapter apply to the terrestrial part of the landfall section. Where specific soil, groundwater or surface water characteristics were observed to be variable across the terrestrial part of the landfall section, descriptions have been provided in further detail for localised zones.

8.2 Scoping

The scope of the soil and water impact assessment for the Project was defined through a scoping process which identified soil and water receptors and potentially significant impacts related to the Project. Baseline information which informed the scoping process largely drew on information gathered from studies undertaken for the South Stream Offshore Pipeline, including feasibility, engineering and environmental surveys carried out since 2008. Key steps in the scoping process for soil and water comprised the following:

- The Project description was reviewed to identify activities with the potential to significantly affect soil and water receptors;
• Soil and water receptors within the Project’s Area of Influence (see Section 8.3.1 for definition) were identified through a process of secondary data review (see Section 8.4.2 for further detail), stakeholder consultation regarding abstractions, previous studies undertaken for the South Stream Offshore Pipeline and professional expertise; and

• A review of relevant national and international legislative requirements and lender requirements.

An Environmental Issues Identification (ENVIID) workshop, which involved Environmental and Social Impact Assessment (ESIA) specialists, South Stream Transport representatives and project engineers, was undertaken to assist in the identification of impacts and receptors. During this workshop, each activity was examined, drawing upon the experience of the technical specialists and their understanding of the extent and nature of the Project Activities and the natural environment, to understand:

• How activities were expected to interact with soil and water receptors, and whether this is likely to result in a beneficial or adverse impact (pertinent activities are described in Section 8.6.1.1); and

• Which receptors will potentially be impacted by each activity and the potential significance of those impacts (key receptors are described in Section 8.6.1.2).

The outcome of the ENVIID workshop was the production of an ENVIID register which identified the various elements of the Project and their interaction or potential impact on sensitive ecological receptors.

The assessment below has therefore been informed through this process of impact and receptor identification.

8.3 Spatial and Temporal Boundaries

8.3.1 Project Area

The Project Area (as described in Chapter 1 Introduction) is subdivided into three sections: the landfall, nearshore and offshore sections. This chapter assesses only the terrestrial part of the landfall section of the Project Area. This extends from the shoreline to the permanent landfall facilities including the Pipeline route (both buried and microtunnelled sections).

8.3.2 Study Area

The Study Area is a terrestrial zone extending up to approximately 1.5 km either side of the centreline of the Pipeline route (Figure 8.1) and landfall facilities boundary. The Study Area has been assessed within a regional context with respect to the geology and river catchments.

8.3.3 Survey Areas

The Survey Area for soil and water is the same as the Study Area and is the area in which surveys were undertaken for the Project.
8.3.4 Zone of Influence

The Zone of Influence has been assumed to be approximately equivalent to the Study Area plus the downstream stretches of the watercourses and the area around the abstraction well at Sukko.

The Zone of Influence includes new roads constructed or upgraded for the Project but not existing roads that extend outside the areas defined above.

The Study Area and Zone of Influence are the same for each Project phase i.e. Construction and Pre-Commissioning Phases; Operational Phase; Decommissioning Phase; and for the assessment of unplanned events (discussed in Chapter 19 Unplanned Events).

8.4 Baseline Data

8.4.1 Methodology and Data

In order to assess potential impacts on soil, groundwater and surface water, secondary (i.e. existing data based on desk-based research) and primary data regarding the relevant baseline characteristics have been identified and assessed. Following this, a gap analysis was undertaken to inform the need for additional primary data sources to fill the data gaps. Primary data was then collected during field surveys.

Data have been collected and presented at different spatial levels as appropriate according to the nature of the potential impact to be assessed and the baseline indicator in question.

The baseline characterisation considered:

- Soil:
  - Soil types; and
  - Soil chemistry.

- Groundwater:
  - Aquifer characteristics;
  - Groundwater levels; and
  - Groundwater chemistry.

- Surface Water:
  - Watercourse characteristics;
  - Surface water chemistry; and
  - Stream bed sediment chemistry.

8.4.2 Secondary Data

Contextual information on the regional setting with respect to soil and water was obtained through literature review. Published geological and topographical maps were reviewed to
Chapter 8 Soils, Groundwater and Surface Water

characterise the ground conditions and local geomorphological and hydrological setting. Meteorological data was based on published datasets.

Consultations with regulators and other stakeholders were undertaken as part of the initial assessment for the Study Area (Ref. 8.1 to 8.7). The consultees included:

- Kuban Basin Water Agency, regarding water consumers;
- Russian Ministry of Natural Resources, regarding sanitary protection zones;
- Russian Ministry of Public Health and Social Development, regarding sanitary protection zones;
- Russkaya Compressor station, regarding water supply;
- Supsekh Administration, regarding water supply; and
- Ministry of Defence regarding the existing water well at Sukko.

8.4.3 Data Gaps

The secondary (existing) data research exercise revealed that there were a number of data gaps. The data gaps were most acute in respect of the following themes:

- Soil characteristics and distribution at the Project-scale;
- Baseline soil, groundwater and surface water chemistry, including potentially existing contamination;
- Groundwater levels; and
- Details of nearby water abstractions, including locations, usage and abstraction rates.

These data gaps have been addressed through field surveys, the details of which are set out in Section 8.4.4.

8.4.4 Primary Data/Baseline Surveys

8.4.4.1 Overview

A number of baseline surveys have been undertaken in relation to soil and water.

Environmental surveys were undertaken in the Survey Area in 2010, 2011 and 2013 (Refs. 8.1, 8.8), and covered the following disciplines relevant to this chapter:

- Landscape;
- Soils;
- Groundwater;
- Surface water;
- Geomorphological geohazards; and
- Contamination.
The field surveys included mapping of soil, geomorphological and hydrogeological features. Samples were obtained of soil, groundwater, surface water and stream bed sediments for laboratory analysis to characterise their physico-chemical properties.

In addition to the environmental surveys described above, engineering surveys have been undertaken (Refs. 8.9, 8.10, 8.11 and 8.12) which included intrusive and non-intrusive geotechnical investigation. These geotechnical investigations included boreholes and geophysical profiling. This has provided additional information on local ground conditions, depth to bedrock, groundwater levels and geomorphology.

The baseline data presented in this chapter is predominantly based on information gathered during the environmental surveys (Ref. 8.1, 8.8).

The survey locations within the Study Area are shown in Figure 8.1.

8.4.4.2 Soil Survey

The purpose of the soil surveys (Ref. 8.1, 8.8) was to:

- Determine the soil spatial distribution, revealing the full range of dominant and associated soils,
- Assess the natural variation of their morphogenetic properties; and
- Assess the agro-chemical soil properties where applicable.

The soil studies were carried out according to requirements Russian standard SanPiN 11-207-97 and the All Union Instruction on Soil Investigation 1973 given in the Peter Gaz survey reports (Ref. 8.1).

The soil survey in the Study Area was undertaken along three linear survey lines oriented roughly perpendicular to the coast with a small number of additional sites in other areas. In total, 65 soil profile sections were undertaken using pits excavated to a depth of approximately 0.9 m.

The geomorphology of the Study Area was assessed by field mapping and profiling at selected locations. The geomorphological survey identified and assessed geomorphologically active features.

8.4.4.3 Soil Quality

The purpose of the soil quality surveys was to determine the baseline soil chemistry.

During the 2010 investigation (Ref. 8.1), 30 soil samples were collected from 16 locations at varying depths. During the 2013 investigation (Ref. 8.8), 10 soil samples were collected from five locations. Samples underwent laboratory analysis of physico-chemical properties and agrochemical nutrient levels.

To evaluate the potential for chemical contamination of soils, sampling was carried out on test plots within the Survey Area. Forty two composite soil samples were prepared by mixing equal volumes of not less than five samples taken from the test plot (no smaller than 5×5 m)
uniformly throughout the depth of the layer 0 to 0.1 m. During collection, odour, texture, presence of films, oil stains, inclusions and organic content (presence of peat) were noted. Sampling, preservation, storage and transportation were carried out in accordance with the requirements of Russian standards; GOST 17.4.3.01-83 and GOST 17.4.4.02.84 (Ref 8.1).

**8.4.4.4 Groundwater Quality**

During the 2010 investigation a total of three water samples were collected from springs within the Survey Area in accordance with Russian standard SP 11-102-97. During the 2013 investigation a further three water samples were collected from additional springs in accordance with Russian standard SP 11-102-97. Sampling, preservation, storage and transportation of water samples were carried out in accordance with the requirements of Russian standards GOST 17.1.5.05-85 and GOST R 51592-2000 (Ref 8.1). The water was collected by hand in disposable plastic containers and glass bottles.

Air and water temperature were measured and field observations of colour, odour, turbidity, and taste were made. Immediately following sampling, the pH and dissolved oxygen content were determined. Samples were refrigerated (temperature 2 to 5°C) and delivered to the laboratory.

**8.4.4.5 Surface Water Quality**

During the 2010 investigation a total of four surface water samples were collected within the Survey Area in accordance with Russian standard SP 11-102-97 (Ref. 8.1). During the 2013 investigation a further two water samples were collected in accordance with SP 11-102-97. Sampling, preservation, storage and transportation of the samples were carried out in accordance with the requirements of Russian standards GOST 17.1.5.05-85 and GOST R 51592-2000 (Ref. 8.1). Water samples were collected at a depth of 0.2 to 0.5 m by hand in disposable plastic containers and glass bottles.

Air temperature, water temperature, water depth and water clarity were measured and field observations of colour, odour and turbidity were made. Immediately following sampling, the pH and dissolved oxygen content were determined. Samples were refrigerated (temperature 2 to 5°C) and delivered to the laboratory.

**8.4.4.6 Stream Bed Sediment Analysis**

Within the Survey Area a total of six stream bed samples were collected at the same locations as the surface water quality samples. Sampling, preservation, storage and transportation of the samples were carried out in accordance with the requirements of Russian standards GOST 17.1.5.01-80 and RD 52.24.609-99 (Ref. 8.1). The sediments were sampled from the depth 0 to 5 cm. During collection, odour, texture, presence of films, oil stains, inclusions and organic content were noted.

**8.4.4.7 Laboratory Analysis**

The laboratory analysis for the Survey Area soil and water samples was undertaken in the: Test Laboratory Centre (TLC GC RES LLC), the Environmental Analytical Laboratory of Peter Gaz, and the laboratory of the RSC Kurchatovskiy Institute.

8.4.5 Data Assumptions and Limitations

The available soil, water and sediment data are sufficient to inform the baseline of the study in order to determine the potential for impacts and undertake the assessment.

The following limitations apply to the baseline dataset:

- There is limited soil data on the exact route of the permanent and temporary access roads. However, it is considered there is sufficient data from the Survey Area as a whole to infer likely ground conditions along the new access roads;

- Groundwater and surface water quality was sampled on two occasions. However, groundwater and surface water quality may be subject to fluctuations and a single sampling event may not be fully representative of long-term water quality patterns. Parameters such as suspended solids and dissolved oxygen may vary naturally in response to flow rates and following rainfall events;

- Groundwater was sampled from springs rather than boreholes;

- There are limited hydrological flow regime measurements. The flow regimes of the surface watercourses vary in response to rainfall. Hydrological modelling based on catchment size and run-off estimates in small catchments with permeable bed sediments that are partially fed by springs tends to give results with a high degree of uncertainty. However, further quantification of the flow regime would not alter the outcome of the impact assessment;

- There is uncertainty over the exact locations of nearby abstractions (Refs. 8.3, 8.5). The nearest confirmed groundwater abstraction (which is associated with the Russkaya Compressor station) is understood to be at more than 5 km to the northeast of the Study Area; the Project does not lie within a sanitary protection zone of this abstraction (Ref. 8.3). Anapa Administration have confirmed there are no licensed abstractions in the vicinity of the Project Area (Ref. 8.7);

- The closest surface water abstractions to the Study Area are reported to be upstream of the Pipeline route (Ref. 8.5). There is a potential abstraction point from surface water upstream of the road crossing on Graphova Gap but there is no information as to the volumes or timings of abstraction at this location; and

- Information is available on the Russian Ministry of Defence water supply well located in Sukko proposed to be used by the Project but there is limited information on any other groundwater abstractions in and near Sukko. It has been assumed that the current abstraction licence limits for the proposed water source is adequately protective of other abstractors in the region.

8.5 Baseline Characteristics

This section first introduces the policy, regulatory and administrative frameworks and goes to identify the national and international standards relevant to soils, groundwater, surface water, and sediment. It provides a description of the baseline, i.e., “pre-existing” environment
conditions, compares those conditions against the national and international standards, and then describes the existing status with respect to administrative frameworks.

8.5.1 Applicable Standards

The legal framework of relevance to the Project is outlined in Chapter 2 Policy, Regulatory and Administrative Framework. Additional, more specific regulations of relevance to soils, groundwater, surface water and sediment conditions include the following Russian national standards on soil and water quality:

- Russian standard GN 2.1.7.2041-06, on maximum permissible concentrations (MPCs) of chemical substances in the soil (Ref. 8.13);
- Russian standard GN 2.1.7.2511-09, on approximate permissible concentrations (APCs) of chemical substances in soil (Ref. 8.14);
- Russian standard GN 1.2.2701-10, on hygienic regulations of pesticides in the environment (list) (Ref. 8.15);
- Russian standard GN 2.1.5.1315-03, on MPCs of chemical substances contained in water of water bodies for economic-potable and social-domestic water use (Ref. 8.17);
- Russian standard SanPiN 2.1.5.980-02, on hygienic requirements for quality of water from non-centralised water supply systems. Sanitary protection of water sources (Ref. 8.16);
- Russian standard GN 2.1.4.1110-22.1.4 on drinking water and water supply of populated areas, zones of sanitary protection of water sources (Ref. 8.20);
- Article 65 of the Water Code of the Russian Federation (Ref. 8.21); and
- Russian standard SanPiN 2.1.7.1287 -03. Soil quality sanitary epidemiological requirements for industrial sites (Ref. 8.22).

Table 8.1, Table 8.2, Table 8.3 and Table 8.4 present the respective relevant soil, groundwater, surface water quality and sediment limits for the Project, based on the regulations detailed above and the World Health Organisation (WHO) Water Quality Guidelines (Ref. 8.23) as recommended by the International Finance Corporation (IFC) Environmental, Health and Safety General Guidelines (Ref. 8.24).

Russian national standards take precedence over international standards because they are generally more stringent and therefore national standards will be used to assess current baseline conditions.

The assessment criteria for soil quality have been based on the following guidance:
- The soil quality assessment has been made using Russian standard GN 2.1.7.2041-06 and Russian standard GN 2.1.7.2511-09. These standards define the MPCs and APCs respectively for various chemical substances permitted to occur in soils; and

- MPC levels specify the concentration of a harmful substance within soil below which there are no significant adverse impacts upon human health and which will not cause detrimental impacts to soil quality. Where MPC levels are not provided for specific pollutants, APC levels are typically used to determine upper limits for contaminants in the soil.

* Russian APC levels vary depending on the soil type encountered (e.g. APC levels may vary depending on whether soils are silty-sandy and sandy soils, sandy loamy soils or loam soil etc.). APC levels presented in Table 8.1 above are representative of clayish and loamy soils with pH>5.5 which are representative of soils in the landfall section (Ref. 8.13).

** In the absence of a soil standard for chromium, the sediment standards (Table 8.4) shall be adopted.

† Soil standards are not applicable for iron as concentrations are primarily controlled by the underlying geology rather than reflecting anthropogenic influences.

± APC levels for total PCBs are taken from the Russian Order of the State Committee for Ecology of Russian Federation from 13.04.99 No. 165 (taken from Ref. 8.25).

†† Permissible Levels of Oil Products are taken from a Letter of the Ministry of Environment and Natural Resources (Ref. ±±8.2, provided within Peter Gaz report Ref. 8.1).

In the absence of a soil standard for phenols, the sediment standards (Table 8.4) shall be adopted. However, it is also*** noted that phenol in soil may be derived from natural materials as well as or instead of anthropogenic sources.

The assessment criteria for groundwater quality have been based on the following guidance:

- Russian standard GN 2.1.5.1315-03, Russian standard SanPin 2.1.4.1175-02, and WHO Water Quality Guidelines. These standards define the recommended maximum concentrations for various chemical substances in groundwater. These concentrations are based on human health considerations where groundwater is used for potable supply.

* There is no WHO standard specified for petroleum hydrocarbons. The adopted value presented here is based on the WHO standard for Benzene (a common component found in petroleum hydrocarbons) and guidance on acceptability for potable supply based on taste and odour.

** There is no WHO standard specified for total organochlorine pesticides. The adopted value presented here is based on the WHO standard for Aldrin and Dieldrin, which is the most stringent of the available WHO standards for organochlorine pesticide compounds.

† WHO value for γ-HCH. No values for α-HCH or β-HCH given in WHO standards.
The assessment criteria for surface water quality have been based on the following guidance:

- Russian standard SanPiN 2.1.5.980-00, Russian standard GN 2.1.5.1315-03, Order of the Federal Fisheries Agency No. 20, and WHO Water Quality Guidelines. These standards define the recommended maximum concentrations for various chemical substances in surface waters. These concentrations are based on human health, amenity and ecological considerations.

* Based on value for γ-HCH. No values for α-HCH or β-HCH given.

In the absence of official Russian standards for stream bed sediments, the standards for the streambed sediments have been based on the current Dutch and Canadian guidelines (Refs. 8.26, 8.27 and 8.28). The Dutch guidelines apply to both soils and aquatic sediments and were derived primarily on human toxicological grounds; these values are widely used throughout Europe. It should be noted that these values are based on standard soil comprising 10% organic matter and 25% clay; the target values may be factored according to the measured organic matter and clay content of the individual sediment samples where sediments differ substantially from the assumed standard soil. The values based on the Canadian interim sediment quality guidelines apply solely for aquatic sediments and are derived primarily on ecotoxicological grounds. Using both standards allows characterisation of baseline sediment quality in the context of the environment in the Study Area.

* The published sediment standard does not include specific limits for Benzo(a)pyrene. Therefore, the limits for Total Polycyclic aromatic hydrocarbons (PAHs) have been adopted here.

8.5.2 Soils

8.5.2.1 Soil Types

Soil types in the survey area have been categorised according to the World Reference Base for Soil Resources (WRB) published by the Food and Agricultural Organisation of the United Nations, International Union of Soil Sciences and the International Soil Reference and Information Centre (Ref. 8.29). The soil types include: cambisols, phaeozems, arenosols, fluvisol, abrazems/regosols and anthropogenic soils, as described in Table 8.5. The soil cover is typically formed through the degradation of the underlying geology. **Chapter 7 Physical and Geophysical Environment** describes the geology and geomorphology of the Study Area.

The distribution of soil cover within the Study Area is presented in Figure 8.2 the distribution has been assessed through field mapping and soil logging. Locations of the soil survey points
are shown on Figure 8.1. Bedrock is locally exposed on the steeper slopes of the river valleys and along the coast.

Agricultural areas (principally vineyards) in the Study Area are predominantly located on arenosols and abrazem/regosols. Vineyard development usually involves one-time ploughing to around 0.6 m followed by annual tillage to 0.3 m (Ref. 8.1).

**Table 8.5 Summary of Soil Types within Study Area**

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cambisols</td>
<td>Cambisols originate from the weathering of underlying parent rock material and form a residual weathered soil that comprises sandy silts and clays. Cambisols still retain some of the original rock structure (e.g. bedding or evidence of jointing/fracturing).</td>
</tr>
<tr>
<td>Phaeozem Soils</td>
<td>Phaeozem soils comprise a dark organic (humus) rich topsoil layer, covered in vegetation, including grass, plants and trees. These soils are typically 0.3 to 0.35 m thick in the Study Area (Figure 8.2) and have a high water absorption capacity and low permeability. Eluvial Phaeozem soils are derived from either the in-situ weathering of underlying bedrock or the weathering of bedrock combined with limited movement or accumulation of the soils due to gravitational creep on gently inclined slopes. Diluvial-Colluvial Phaeozem soils are derived from the erosion and removal of underlying bedrock by flood or landslide events. Diluvial deposits comprise soils which are deposited on alluvial floodplains as a result of sudden flood events, and colluvial deposits comprise typically loose, unconsolidated soils deposited in accumulation fans at the base of hill slopes by run-off, landslides or slope creep.</td>
</tr>
<tr>
<td>Arenosols</td>
<td>Arenosol soils are predominantly sandy in composition (typically &gt;65%) and lack any substantial soil profile and structure. In the Study Area these are typically concentrated in areas associated with flat or gentle terrace slopes located between watercourses.</td>
</tr>
<tr>
<td>Fluvisols</td>
<td>Fluvisols soils are typically located on alluvial floodplains, river fans, valleys and tidal marshes. They form on alluvial soils and can be mixed in with flood surge deposits. Deposits include loam, silts and sandy clays to clayey sands.</td>
</tr>
<tr>
<td>Abrazems/Regosols</td>
<td>Abrazem soils are a poorly developed, unconsolidated (loose) soil, which exhibit no diagnostic horizons. Abrazines are formed as a result of erosion of loose rocks (such as loess, alluvium or sand deposits). Soils are typically formed through landslide and flooding events.</td>
</tr>
</tbody>
</table>

Anthropogenic Soils

<table>
<thead>
<tr>
<th>Soil Type</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anthropogenic Soils</td>
<td>Anthropogenic soils are soils that have been modified by human activity. Within the Study Area, these include soils that have been reworked (not including agricultural activity like ploughing), imported man-made fill and other materials (such as pavements and hard-standing). These soils are typically confined to areas of urban construction and activity, such as the town of Varvarovka (to the north of the Pipeline route), and the coastal access road. No substantial areas of anthropogenic soils have been identified within the Study Area to date.</td>
</tr>
</tbody>
</table>

**8.5.2.2 Soil Quality**

The agrochemical assessment of soils in the Survey Area (Ref. 8.1, 8.8) included the testing of 40 samples from 21 locations. The soils are alkaline, with pH values ranging from 7.22 to 8.8. There was limited variation in soil salinity observed. The soils were typically loams, with fine-grained (<0.01 mm) sediment contents in the range 2.6 to 79.5% but typically around 50 to 75%; the agricultural soils tended to have lower clay contents.

The soils in the agricultural areas had humus content ranging from 1.8 to 6.62%. The phaeozems had humus contents of 3.8 to 7.42%. The fluvisols had humus contents of 3.07 to 5.82%. The soils are characterised by reasonably high nutrient levels (Ref. 8.1, 8.8).

During the 2010 and 2011 surveys, a total of 27 soil samples were also collected for laboratory testing of potential contaminants (Ref. 8.1). During the 2013 survey an additional 15 composite samples were also collected for laboratory testing (Ref. 8.8).

All soil samples were analysed to determine the presence and concentration of a suite of potential contaminants. The results of the analysis were compared with Russian MPC (Ref. 8.13) and APC (Ref. 8.14) levels (Table 8.1). The results of the laboratory analysis are shown in Table 8.6 and the locations of exceedances are shown on Figure 8.3.

*Continued…*
The general pre-existing characteristics of the terrestrial soils in the Study Area are as follows:

- Elevated copper levels were measured in excess of the APC threshold in reworked soils. This may be associated with the use of agrochemicals in vineyard areas (in the northeast of the Survey Area, to the south of the connection pipes linking the onshore pipelines to the Russkaya Compressor station);

- Arsenic levels exceeded MPC thresholds in soil samples taken adjacent to the coastal road. A definitive source for the elevated arsenic has not been identified but a plausible mechanism is surface deposition associated with motor vehicle emissions;

- Benzo(a)pyrene levels exceeded MPC thresholds adjacent to the coastal road. Again this may be as a result of motor vehicle emissions;

- PCB levels exceeded the APC threshold level in the vineyard area in the northeast of the Survey Area, and in a single sample taken at the location of where the pipelines cross the Shingar River. A definite on-site source for the PCBs has not been identified, although the location of the exceedances suggests it may relate to agricultural activities;

- Lead and zinc exceeded the MPC and APC threshold, respectively, in a single sample taken from west of the landfall facility and Graphova Gap. Elevated levels of benzo(a)pyrene were also found in the same location;

- Pesticides were detected in three soil samples, all located in agricultural areas;

- It should be noted that the contamination concentrations for soil samples collected in valley bottoms may not necessarily be due to an immediately adjacent source but, may reflect transport of soils from upstream in the catchment through surface run-off or flood events; and

- In addition to the chemical testing above, local areas of informal waste deposition (‘flytipping’) have been observed, including an in-filled ditch (Ref. 8.30). The materials observed include demolition wastes. There is a potential for contaminants including asbestos to be present in these materials.
Baseline Chemical Concentrations Exceeding Standards

- Soil Contaminant exceeded = concentration level measured, in mg/kg (*Russian MPC level / **Russian APC level)
- Waters Contaminant exceeded = concentration level measured, in mg/l ( *Russian MPC level for drinking & domestic use / **Russian APC level for fishing use)
- e.g. NH = 3.47 (0.05/0.5*)
- Sediment Contaminant exceeded = concentration level in mg/kg

(*Target level / **Guideline level)

8.5.3 Groundwater

8.5.3.1 Hydrogeological Regime

The hydrogeology of the Study Area is characterised by local shallow alluvial aquifers overlying a carbonate aquifer within the bedrock (Ref. 8.1, 8.12).

The alluvial aquifer is present along the narrow (typically less than 200 m wide) river valleys of the Shingar River and an unnamed tributary of the Sukko River. The extent of the alluvial aquifers, in plan view, i.e. looking from above not in cross-section, is anticipated to broadly mirror the distribution of fluvisols (Figure 8.2).

The carbonate aquifer extends across the entire Study Area and beyond into the wider region. The aquifer may be locally subdivided by changes in lithology and faulting. The bedrock strata are locally exposed in the valley walls. The groundwater may be locally at or close to ground level at the base of the valleys. This is implied by the presence of springs. Borehole drilled along (Ref. 8.10, 8.12) the alignment of the proposed microtunnels confirmed that groundwater within the alluvial aquifers is within 10 m of ground level and is sometimes at or near ground level.

The hydraulic conductivity of the alluvium is up to 40 metres per day (m/d) and the saturated thickness of the alluvial aquifer in the Study Area is typically in the order of 4 to 6 m, but may be significantly thicker locally (Ref. 8.10, 8.12). Groundwater recharge to the alluvial aquifer is via rainfall and discharge from surface watercourses along their upper reaches. The alluvial aquifer is anticipated to be in at least partial hydraulic connection with the carbonate aquifer given the bedrock is locally at or near surface. The degree of connection will vary spatially and potentially also seasonally.

Groundwater flow within the underlying carbonate aquifer is controlled by a network of fractures within folded and fractured sedimentary bedrock deposits. The geology is dominated by marls1 but there are also limestone and sandstone beds. Owing to the nature of the local geology, it is likely that the carbonate aquifer comprises a multi-layered aquifer system with varying permeability in the different lithologies present. Groundwater flow is likely to be predominantly through the more permeable horizons such as the sandstones and limestones compared with the lower permeability marls and argillaceous strata. Faults and fracture zones have been mapped within the Study Area as described in Chapter 7 Physical and Geophysical Environment; key areas include around the Marfovsky Fault, which crosses the Graphova Gap near the proposed road crossing, and around the Shingar valley (the valley is aligned with the Shingarsky Fault). Additional zones of higher permeability and of increased hydraulic connectivity between individual geological units may occur in these faults and the associated fracture and fissure zones. No evidence of karstic features, i.e. area of limestone in which erosion has produced fissures or caverns, has been observed in the Study Area (Ref. 8.1).

---

1 Assumed from description as “chalky clay”
Chapter 8 Soils, Groundwater and Surface Water

The anticipated depth to the water table varies between ground level to a few metres deep along the valley floors (where groundwater is in hydraulic continuity between the alluvium and carbonate aquifers) and up to 100 m beneath the higher areas along the interfluves (Ref. 8.12). Water levels measured during drilling (Ref. 8.12) included strikes at multiple depths within the same borehole; this is consistent with a layered aquifer system.

Recharge to the aquifers is via rainfall, through groundwater flow from up-hydraulic gradient and recharge from the watercourses in the base of the valleys.

Groundwater discharges to the surface watercourses via ephemeral springs.

8.5.3.2 Abstractions

The groundwater abstraction associated with the proposed Russkaya Compressor station is located approximately 5 km to the northeast of the landfall section (Ref 8.3). The abstraction is used for drinking water and industrial purposes for the Russkaya compressor station. The Project does not lie within the designated sanitary protection zone for this abstraction.

The nearby vineyard, Agrofirma Kavkaz, sources the majority of its water from the Supsekh municipal water supply system with the remainder of the water being obtained from the unlicensed surface water abstraction (Section 8.5.5.3) (Ref. 8.4). This abstraction is understood to be upstream of the Project Area (Ref. 8.4).

The majority of the water supply for the neighbouring residential area of Varvarovka is sourced from the Supsekh municipal water supply system with the remainder being supplied by the Kavgaz water supply system (Ref. 8.4).

The terrestrial part of the landfall section does not lie within a source (sanitary) protection zone associated with a groundwater abstraction.

The proposed source of potable water for the Project is from an existing water supply at Sukko. This water supply is understood to be owned by the Russian Ministry of Defence but is also utilised by third parties.

Information has been provided (Ref. 8.7) for three boreholes, named operational borehole No.2P (also referred to as No.2), No.4D (also referred to as No.4) and No.4P. The boreholes are located within the Kiblerova valley in the northern part of the town of Sukko; the bores are located is approximately 2 km south of the proposed landfall facilities. Records indicate that No.2P is furthest south, with No.4P and No.4D located further to the north. The boreholes are close to the unnamed tributary of the Sukko River and are about 600 m from the main Sukko River. There is a 50 m radius protection zone around the borehole.

The operational borehole, No.2P (Reference code 34629), was drilled to a depth of 60 m in 2003. The geological log indicates that the upper 32 m comprised clay loam, overlying 6 m of poorly sorted cobbles, gravel and sand (probably weathered and fractured bedrock or scree

---

2 Supsekh is located to the north of Varavrovka
deposited during the original erosion of the valley), in turn overlying 22 m interbedded mudstones, marls and fractured sandstones of Upper Cretaceous age. The geology is consistent with the conceptual model of the regional hydrogeology of alluvial aquifer in valleys over sedimentary bedrock aquifer.

The borehole construction of No.2P consists of 219 millimetres (mm) solid casing to a depth of 33 m, with a 4.5 m screened section to a depth of 37.5 m. The borehole is 190.5 mm diameter open hole from a depth of 38 m to the base of the hole at 60 m depth. Therefore, the water is abstracted primarily from the bedrock aquifer. Hydraulic testing of the borehole was undertaken in February 2003. Borehole No.2P was airlifted for 48 hours at a flow rate of 1.5 litres per second (l/s), around 130 cubic metres per day (m$^3$/day), which, created a drawdown of 8 m from the rest groundwater level of 13 m depth i.e. a pumping groundwater level of 21 m depth. Therefore the specific capacity of the borehole was estimated to be 0.19 litres per second per metre (l/s/m). It was recommended that the pump should be set at a depth between 25 and 30 m depth i.e. within the solid casing. However, it is uncertain if the current pump is installed within that depth range.

Borehole No.4D is an exploration borehole that was drilled in 1996; it is assumed that this borehole still exists. It had a diameter of 324 mm to 19 m depth and then a 219 mm diameter to the end of the borehole at 60 m depth, with screened horizons between 25 to 30 m and 52 to 57 m depth. The rest groundwater level before pumping was recorded as 0.3 m depth and the pumping water level as 15.5 m depth. However, the abstraction rate was not recorded.

Borehole No.4P is an exploration borehole for fresh water that was drilled in 1981; it is assumed that this borehole still exists. It has a diameter of 325 mm to 22.8 m depth and a 168 mm diameter to the end of the borehole at 27 m depth, with a screened horizon between 22.8 and 27.0 m. The rest groundwater level before pumping was 0.6 m depth and the pumping water level was 12.9 m depth. However, the abstraction rate was not recorded.

Abstraction from the Sukko source is seasonally restricted. Water may only be abstracted between October and April; it is understood that the restriction on summer abstraction is in place to prevent derogation of the aquifer.

8.5.3.3 Groundwater Quality

During the 2010 survey, groundwater samples were taken from three ephemeral springs (one sample per spring), the locations of which are shown in Figure 8.1. During the 2013 survey, groundwater samples were taken from three additional springs, the locations of which are also shown on Figure 8.1. The springs are located in the valleys. There is uncertainty as to whether the groundwater emerges from the alluvial or bedrock aquifers; this may vary from spring to spring and may also change seasonally. The groundwater samples were analysed to determine the presence and concentration of a range of major ions, metals and organic compounds. The results were compared with Russian water quality standards for potable and amenity use (in Section 8.5.1); the results were subsequently compared with the WHO standards, where appropriate. The groundwater quality results are summarised in Table 8.7.

---

3 The groundwater samples are labelled BГX on the figure for ease of comparison with survey data and with EIA.

* n/a: Not assessed, as no value provided in relevant standards.
** n/a: Total of potassium and sodium.
† Pentachlorobenzene, Heptachlor, Aldrin, Heptachlor Epoxy, Methoxychlor, Trans-chlordane, Cis-chlordane, Trans-nonachlor and Mirex.
± Detection limit exceeded OCP standard of 0.01 µg/L.

The general pre-existing characteristics of groundwater from the sampled springs in the Study Area are as follows:

- Typically clear in colour, pH neutral (pH 6.8 to 6.9), and is fresh in composition (salinity content 656 to 764 mg/l);
- Groundwater has a strong calcium hydrocarbonate chemical signature, indicating aquifers in the Survey Area typically comprise soils or rock rich in calcium carbonate;
A single sample exceeded the iron MPC for drinking and domestic water quality standards (Ref. 8.17), where a level of 0.58 mg/l was recorded compared to a threshold value of 0.3 mg/l. No other heavy metals were detected at elevated concentrations;

A single sample (taken 0.2 km south of Varvarovka) exceeded the hydrocarbon MPC for drinking and domestic water quality standards (Ref. 8.17), where a level of 0.59 mg/L was recorded compared to a MPC threshold value of 0.3 mg/l. All three samples exceed the WHO standard for benzene (0.01 mg/l), which has been applied as a surrogate standard in the absence of a WHO standard for petroleum hydrocarbon. Petroleum hydrocarbons at the measured concentrations may also not be suitable for potable supply on the grounds of taste and odour;

All three 2013 survey samples exceeded the anionic surfactant MPC for drinking and domestic water quality standards;

Pesticides were detected in two samples during the 2013 survey. These reflect the agricultural nature of the catchment; and

There were no other exceedances where screening criteria are available (Refs. 8.16, 8.17 and 8.23). PCBs were detected, albeit in low concentrations, during the 2013 survey.

Water quality samples from operational borehole No. 2P at Sukko were recently tested to check for compliance against drinking water standards4 (Ref. 8.6). Samples were collected from the “clear water reservoir” in May and July 2013. Additionally a sample was obtained from the “communal (network)” in July 2013. No groundwater quality data from July 2013 was provided. However, according to the data table for the May 2013 sample, the water quality measurements were within the acceptable range for potable use. The groundwater was slightly alkaline (pH 7.5), mineralised (838 mg/l) and of calcium bicarbonate type; the water quality was similar to that measured within the Survey Area5. The water quality at the Sukko water supply source is required to be monitored at least annually.

8.5.4 Surface Water

8.5.4.1 Surface Water Bodies

Two watercourses, the Shingar River and an unnamed tributary of the Sukko River that drains the Graphova Gap, will be crossed by the proposed Pipeline route within the Study Area. The locations of these surface watercourses are shown on Figure 8.4. Photographs of the Shingar River and the Graphova Gap are shown in Figure 8.5.

The Shingar River flows south across the Study Area and enters the Black Sea to the south-southwest of the microtunnel entry shaft site. The Shingar River is aligned with the Shingarsky Fault (Chapter 7 Physical and Geophysical Environment). The pipelines will be

4 SanPin 2.1.4.1074-01 “Drinking water. Health and safety requirements on water quality of centralised water supply systems. Quality control”

5 Note that the water quality testing for the Sukko borehole did not include testing for some of the types of contaminants detected in the Survey Area such as pesticides or oil products.
microtunnelled beneath the Shingar River. There is a tributary on the eastern side, immediately to the north of the microtunnel entry shaft site and adjacent to the temporary access road route.

The unnamed watercourse in the Graphova Gap runs south across the Study Area then continues to flow south until its confluence with the Sukko River in the town of Sukko. The pipeline will cross this watercourse in open-cut. The watercourse will also be crossed by an access road.

A third watercourse, a tributary which drains the Kiblerova Gap (referred to as the Kiblerova Gap) is located in the Study Area to the east of the landfall facilities. This watercourse does not cross the Project Area but crosses the connection pipeline route to the Russkaya compressor station. The tributary in the Kiblerova Gap enters the Sukko River upstream of the confluence with the Shingar River. The tributary runs close to the water abstraction source in Sukko.

A 50 m wide sanitary protection zone (Ref. 8.20) extends around each of the above watercourses. Within the protection zone all activities are controlled to prevent contamination and silting of the water body, and to conserve the habitat for aquatic biological resources and other flora and fauna.

In accordance with Paragraph 15 and Paragraph 16 of Article 65 of the Water Code of the Russian Federation, the following is prohibited within the borders of water protection zones:

- Use of sewage to fertilise soils;
- Cemeteries, animal burials, production and consumption waste disposal sites, chemical, explosive, toxic, poisonous and toxic substances, radioactive waste disposal facilities;
- Use of aviation to combat pests and plant diseases; and
- Traffic or parking of vehicles (except for special vehicles), with the exception of traffic on the roads and parking on the roads and in specially equipped paved areas.

### 8.5.4.2 Hydrological Regime

Limited information is available regarding flooding and hydrology associated with the watercourses within the Study Area. There is no long-term monitoring flow or level data. Anecdotal evidence and inferences based on topography and geomorphology have been used to assess the flow regimes.

The Shingar River is approximately 5.5 km long and flows into the sea to the southwest of the landfall section. The source of the river is a spring within the town of Varvarovka, to the north of the proposed Pipeline route. The catchment area upstream of the Pipeline crossing is estimated to be around 9.35 km$^2$ (Ref. 8.31). The average slope of the catchment is 176% and the slope of the channel in the landfall section is 15% (Ref. 8.31). In the area of the proposed Pipeline crossing, the Shingar River is approximately 1.5 to 3.5 m wide. The valley in the vicinity of the Pipeline route is around 55 to 65 m wide with a floodplain around 1 to 1.5 m above the bank of the river. The river has a weakly meandering form in this area; faulting in the area has influenced erosion patterns and thus the route of the river. The Shingar River has low flow during the summer and autumn months and a more substantial flow during the winter months.
Measured water depths were 0.6 m in December 2010 (Ref. 8.1) and 0.15 m in July 2011 (Ref. 8.31).

Downstream of the landfall section, the Shingar River passes beneath the road to Anapa. The crossing comprises a reinforced concrete overflow structure (4 m wide and 2.4 m high) (Ref. 8.31). The estimated mean low water flow rate is 0.004 cubic metres per second (m$^3$/s) whereas the estimated high flows are 29.03 m$^3$/s (10% occurrence) and 39.23 m$^3$/s (1% occurrence) (Ref. 8.31).

An unnamed tributary of the Sukko River is located 1.5 km to the east of the Shingar River in the Graphova Gap. This watercourse is approximately 2 to 4 m wide, and has ephemeral flow during the summer months and more substantial flow during the winter months. The Pipeline crossing at Graphova Gap is upstream of the mapped floodplain (Ref. 8.1). The catchment upstream of the Pipeline crossing is 1.8 km$^2$ (Ref. 8.31). The average slope of the catchment is 201% and the slope of the channel where the Pipeline route crosses the watercourse is 55% (Ref. 8.31). The measured water depth was 0.1 to 0.3 m in December 2010; in summer the watercourse is reported to be predominantly dry. The watercourses in the Study Area are typically ephemeral, which means they have a flow regime which is variable and directly related to rainfall patterns, with very low flows during periods of little or no rainfall. The ephemeral nature is primarily due to the small catchment size of the area and the seasonal patterns of precipitation. In addition, surface waters are partly recharged from high groundwater tables, often associated with springs that are encountered across the Study Area. There are springs upstream and downstream of the landfall section.

In addition to the natural watercourses, there are artificial drainage ditches locally within the Study Area. These are understood to be used to manage flood risk locally (Ref. 8.1).

Average annual rainfall in Anapa$^6$ is 539 mm. December, January and February are typically the wettest months, with precipitation occurring typically 15 days a month. Average monthly rainfall is less than 50 mm even in winter. The majority of precipitation falls as rain. Precipitation may include snow in winter, particularly between November and April. In contrast the monthly average rainfall in August is 15 mm and rain falls on average on six days of the month. The maximum recorded daily precipitation in Anapa is 85.9 mm.

During summer months when precipitation is less and evapotranspiration is higher, most surface water infiltrates the underlying soils with low flows being observed in the watercourses. This typically results in watercourses becoming dry or the formation of discrete pools of water within the river bed.

Surface water flows typically peak during winter months when rainfall is highest. Under extreme rainfall events, flash flooding may occur.

Both surface watercourses flow approximately north to south across the proposed Pipeline route. The route of the proposed Pipeline crosses the watercourses at right angles. The Pipeline will pass beneath the Shingar River in microtunnels; no surface works are planned at the river.

---

$^6$ The closest meteorological station to the Study Area, located about 10 km to the northwest
The watercourse in the Graphova Gap will be crossed by the Pipeline using open-cut construction techniques, as well as by the proposed access road to the construction site of the landfall facilities, as shown in Figure 8.4.

There are no licensed surface water abstractions for drinking water supply within the Study Area (Ref. 8.7). There is a small impoundment on the watercourse in the Graphova Gap located immediately upstream of the proposed access road crossing (Figure 8.5). This impoundment structure retains surface water flows to enable abstraction; it is probable the choice of location reflects the likely presence of springs\(^7\) in this area.

### 8.5.4.3 Surface Water Quality

There are no long-term data available on surface water quality in the Survey Area. Spot sampling information on water quality has been obtained through the environmental monitoring undertaken in December 2010 (Ref. 8.1) and in June 2013 (Ref. 8.8). It should be noted that it was raining at the time the samples were collected in 2010. During the 2010 survey, four surface water samples were collected and analysed: two samples from the Shingar River (one sample taken from upstream (VPKh-1) and the other taken from downstream (VPKh-2) of the proposed Pipeline crossing), one taken from the Graphova Gap (VPKh-3) and one from the Kiblerova Gap (VPKh-4). Sampling locations are shown on Figure 8.1. Further details of the 2010 survey surface water sample points are given in Table 8.8.

For Information
During the 2013 survey (Ref. 8.8) two surface water samples were collected and analysed: one sample from the tributary running through Graphova Gap at the approximate location of the access road crossing (wp1) and the other taken from the Shingar River (wp2) in approximately the same location as VPKh-2, downstream from the Pipeline.

The surface water samples underwent field and laboratory analysis to assess water quality. The results were compared with Russian National Limit Values for surface water (Refs. 8.17, 8.18 and 8.19); where appropriate the results were also compared with the WHO guidelines (Ref. 8.23) (Table 8.3). The results of the water quality survey are shown in Table 8.9.

The general pre-existing characteristics of surface waters in the Study Area are as follows:

- Surface water colour is predominantly due to the presence of high concentrations of degraded organic material (humus) and the iron content of the soils;
- The surface waters are generally pH neutral (7.0 to 7.1);
- The surface waters are mineralised. The water quality data is consistent with a significant proportion of the observed surface water flow being derived from groundwater;
- The surface water quality contains evidence of anthropogenic pressures on the local water environment, predominantly relating to agricultural activity in the catchment;
- For all surface waters, elevated copper levels exceeded the standards for fisheries water bodies; elevated copper may be associated with surface water runoff from vineyard areas.
Chapter 8 Soils, Groundwater and Surface Water

(Where copper-based agrochemicals are potentially used for controlling parasites). Copper levels were within the Russian standards for amenity and general use;

- Water in the Shingar River exceeded the relevant standards for several parameters including: phosphate, iron, copper, nitrates, sulphates, mercury, phenols, oil products, pesticides and surfactants;
- Water sampled from the unnamed tributary running through the Graphova Gap exceeded the relevant standards for several parameters including: phosphate, iron, copper, sulphate, ammonia, phenols, oil products, pesticides and surfactants;
- Water sampled from the unnamed tributary running through the Kiblerova Gap exceeded the relevant standards for several parameters including: phosphate, copper, nitrite, sulphate and phenols;
- Water quality in 2010 and 2013 was broadly similar. The surface water was slightly more mineralised and alkaline in 2013. The 2013 samples were collected in summer whereas the 2010 samples were obtained in winter. Seasonal variations in baseflow component may have caused the variation in mineralisation;
- In the 2013 survey, water in the Shingar River and tributary running through the Graphova Gap had elevated concentrations of pesticides present. No pesticides were detected in 2010\textsuperscript{8}. The difference may relate to the seasonal variations in agricultural activity in the catchment;
- PCBs were detected in the surface water samples in the 2013 survey. However, the measured concentrations were below the relevant standards;
- Some of the observed elevated concentrations, such as iron, sulphate and phenols, may be due to natural processes rather than to anthropogenic contamination; and
- Water quality, particularly with respect to parameters such as dissolved oxygen and suspended solids, is likely to vary in response to seasonal fluctuations in flow rates and in response to rainfall events.

The locations of known exceedances of surface water quality limits for both drinking and domestic use and fishery water bodies are shown on Figure 8.3.

8.5.4.4 Stream Bed Sediment Quality

Stream bed sediment samples were collected at the same locations as the surface water quality samples in 2010 and 2013 (Ref. 8.1, Ref. 8.8).

The samples were taken from the top 5 cm of the sediments. No visual or olfactory evidence of contamination was observed in the sediment during sampling. The sediments ranged from sands to silty clays. The proportion of fine-grained sediment (<0.01 mm) in the stream bed sediments ranged from 6.9 to 48.9%. The proportion of humus ranged from 3.3 to 8.9%.

\textsuperscript{8} Note that the analytical methodology varied between the two monitoring rounds.
The stream bed sediment samples underwent laboratory analysis to assess sediment quality. The results were compared with the adopted guidelines (Table 8.4). The results of the stream bed sediment survey are shown in Table 8.10.

The general pre-existing characteristics of stream bed sediments in the Study Area are as follows:

- The stream bed sediments show evidence of anthropogenic impacts. Pesticides, PCBs, and oils have been detected in all samples at concentrations that exceed the adopted standards;...
• Phenols were detected in the stream bed sediments at concentrations that exceeded the adopted standard. It is possible that the phenol concentrations are due, at least in part, to natural organic material in the sediment;

• Metals are also present in the stream bed sediments. Cadmium and copper are present in concentrations that exceed the adopted standards; and

• Comparison of the surface water quality and stream bed sediments suggests that some contaminants, such as PCBs, may be present at elevated levels in the sediments without necessarily adversely impacting water quality.

The locations of known surface water pollution exceedances in stream bed sediments in the Study Area are shown on Figure 8.3.

8.5.5 Baseline Summary

8.5.5.1 Soils

Soils in the Study Area comprise cambisols, phaeozems, arenosols, fluvisols, abrazems/regosols and anthropogenic soils.

Soils used for existing agricultural purposes, predominantly arenosols and abrazem/regosols, are important to local land users. The soils provide a substrate that has the physical qualities and/or degree of productivity to support agricultural use.

Of the soil types that will be crossed by the proposed Pipeline route, phaeozem soils are of particular note given that they are structurally prone to compaction and erosion, and vulnerable to contamination through surface spills. The soils typically comprise a soft organic rich topsoil layer, covered in vegetation. It is also noted that phaeozem soils have a high water absorption capacity and play a key role in water regulation.

Fluvisols are present in the valley bottoms and play a role in the hydrological cycle. As they are associated with watercourses and valley bottoms they may be in continuity with shallow groundwater and can act as pathways for movement of chemical contaminants into groundwater and surface water.

The other soil types (cambisols and anthropogenic soils) are less likely to be used for agriculture and are not typically as rich in organic materials as phaeozem soils.

Pre-existing elevated concentrations, i.e., above MPC thresholds, of arsenic, copper, lead, zinc, benzo(a)pyrene, PCBs and pesticides were measured in the soil.

8.5.5.2 Groundwater

The hydrogeology of the Study Area is characterised by shallow alluvial aquifers overlying a carbonate aquifer.

The alluvial aquifer is present along the narrow river valleys of the Shingar River and an unnamed tributary of the Sukko River located in the Graphova Gap. Groundwater flow within the underlying carbonate aquifer is controlled by a network of fissures within folded and
fractured sedimentary bedrock deposits. There is the potential for a hydraulic connection between the alluvial groundwater and the carbonate aquifer.

Recharge to the carbonate aquifer is via rainfall, groundwater flow from up-hydraulic gradient and recharge from the shallow alluvial aquifers.

In the lower reaches of the valleys, groundwater is likely to discharge to the river system and ephemeral springs during periods of high rainfall and corresponding groundwater levels within the alluvium.

The groundwater abstraction associated with the proposed Russkaya compressor station is located approximately 5 km to the northeast of the landfall section (Ref. 8.3). The Project does not lie within the designated sanitary protection zone for this abstraction.

The nearby vineyard, Agrofirma Kavkaz, and the residential area of Varavrovka source the majority of their water from the Supsekh water supply system with the remainder of the water being obtained from the unlicensed surface water abstraction, located upstream of the Project Area (Ref. 8.4).

There is a groundwater source at the Russian Ministry of Defence site in Sukko about 2 km south of the landfall facilities. This abstracts groundwater from three boreholes in the bedrock aquifer. The water is fresh and potable. No abstraction from this source is permitted from May to September.

During the 2010 and 2013 surveys groundwater samples were taken from springs within the Survey Area. The groundwater is fresh and mineralised. Elevated concentrations of iron, oil, surfactants and pesticides have been detected.

### 8.5.5.3 Surface Water

Watercourses in the Study Area include two watercourses crossed by the proposed Pipeline route, the Shingar River and an unnamed tributary of the Sukko River within the Graphova Gap. There is a third watercourse within the Study Area, which is another tributary of the Sukko River within the Kiblerova Gap, but this is located outside the Study Area.

Watercourses in the Study Area are predominantly precipitation fed, with frequent and short floods. In addition, surface waters are partly recharged from high groundwater tables during the winter months. Surface water flows typically peak during winter months when rainfall is highest. During summer months watercourses may become dry or form discrete ponds or small lakes of water within the river bed. Flood events occur in response to storm events. Flooding may trigger geomorphological features such as mudflows and landslides.

There are no licensed abstractions from surface water in the Study Area. There is a small impoundment on the watercourse in the Graphova Gap immediately upstream of the proposed access road crossing. From consultation meetings held with Kavkaz Winery, it is understood that the impounded water is used to irrigate the winery.

Surface water quality samples were taken in 2010 and 2013 (Ref. 8.1 and Ref. 8.8). The water was fresh and mineralised, indicating a significant groundwater baseflow component. Elevated concentrations of contaminants have been detected in the surface waters, including ammonia,
sulphate, phosphate, nitrate, nitrite, mercury, iron, copper, oil, surfactants, phenols and pesticides. Stream bed sediment samples were collected at the same locations as the surface water quality samples. Elevated concentrations of contaminants have been detected in the sediments, including cadmium, copper, oil, phenols, PCBs and pesticides.

8.6 Impact Assessment

8.6.1 Impact Assessment Methodology

The impact assessment methodology is based on the principles of source-pathway-receptor. The source in this context has been identified in relation to the planned project Activity. Owing to the complexity of the Project, there are multiple sources. The receptors under consideration relate to soil, groundwater and surface water. Indirect receptors that use soil, groundwater and surface water have also been considered. Pathways that could link the sources and receptors have been identified. Only where the complete linkage of source, pathway and receptor are present can impacts potentially occur.

An overview of the process followed in compiling the ESIA Report and the general methodology adopted in assessing impact significance is presented in Chapter 3 Impact Assessment Methodology.

While there are a number of national and international soil, water and sediment quality standards applicable to the Project, there is relatively little guidance available describing how the significance of potential impacts on soil, water and sediment should be assessed. Based on the general methodology outlined in Chapter 3 Impact Assessment Methodology, on professional judgement and experience, and on the applicable Project standards and regulations, a series of impact significance criteria were developed to assess potential impacts on soil, water and sediment. A summary of the receptor sensitivity and impact magnitude criteria used in the assessment is presented below.

The combination of the magnitude of impact and receptor sensitivity criteria is assessed in a sensitivity matrix within Chapter 3 Impact Assessment Methodology to generate impact significance categories (High, Moderate, Low or Not Significant).

Measures to avoid or reduce any Moderate or High category (significant) impacts are then developed (where such measures are practical) and any residual impacts of the Project are reported.

8.6.1.1 Project Activities

The potential impacts are derived through the activities of the Project. These are described in detail in Chapter 5 Project Description. Table 8.11 outlines the key activities that are likely to interact with the existing soil, sediment, groundwater and surface water receptors.

## Phase

### Activity

**Pipeline pull-in through microtunnels, including:**
- Excavation of foundation area for pipe pull winches or sheaves within microtunnel construction area;
- Shore pull of Pipeline from offshore pipe-lay vessel;
- Welding of tie-in at microtunnel reception pit; and
- Grouting of annular gap between Pipeline and tunnel case following pipeline installation and pre-commissioning tests.

**Open trench pipe-laying activities – from microtunnel entry shafts to landfall facilities, including:**
- Land clearance, grading, topsoil stripping;
- Diversion of existing utilities and drainage infrastructure;
- Excavation of trench and storage of excavated materials;
- Padding of trench bottoms;
- Dewatering of trench (if required);
- Stringing of Pipeline;
- Line up and bending of pipe;
- Welding of pipe sections and coating of welding joints;
- Pipe lowering in trench;
- Backfill of trench; and
- Restoration.

**Construction of landfall facilities, including:**
- Land clearance, grading, topsoil stripping;
- Diversion of existing utilities and drainage infrastructure;
- Excavation of foundations, underground chambers and areas for hardstanding formation;
- Delivery of construction materials;
- Formation of concrete structures and hardstanding areas;
- Erection of buildings and structures;
- Mechanical assembly and connections;
- Welding of pipe sections and coating of welding joints;
- Site surfacing;
- Painting of infrastructure;
- Restoration; and
- Generation of wastes and wastewaters.

**Pre-Commissioning**

**Pre-commissioning activities associated with pipeline testing, including:**
- Receipt of pipeline inspection gauges (PIGs); and
- Hydro-testing of pipelines.

</tr>
<tr>
<td></td>
<td>The injection of gas and Pipeline pressurisation has no potential to impact soil, groundwater or surface water during this phase. Heating of the gas is necessary as the pressure of the gas from the Russkaya compressor station is much higher than that required for transport in the Pipeline. Hence, the gas is a lower temperature (see Chapter 5 Project Description for more details). During commissioning, the temperature of gas in the Pipeline will not be any higher than during operation. As such, no impact from this activity is anticipated on soil, groundwater or surface water and commissioning activities are not considered in the assessment.</td>

</tbody>
</table>

A number of design controls have been incorporated into the Project design which, reduce the potential impacts from a given Project Activity. Potential Construction and Pre-Commissioning Phase impacts are assessed on this basis. Additional mitigation and monitoring measures are
then identified that can further reduce impacts to as low as reasonably practicable (ALARP), and the residual impact is identified.

Design controls are presented in Chapter 5 Project Description. Those of particular relevance to soil and water include:

- Microtunnelling below the Shingar River;
- Deepening of the Pipeline below the Graphova Gap to maintain sufficient Pipeline depth below the valley floor;
- Construction of a level platform for the landfall facilities, which will include stabilisation of the surrounding slopes;
- Drainage to manage surface run-off, which will be constructed along access roads and at the landfall facilities;
- The use of geotextiles in the construction of permanent and temporary access roads;
- Stripping and stockpiling topsoil (stockpiles will normally be less than 2 m in height) for later use during reinstatement;
- Backfilling of trenches, which will normally occur immediately after the Pipeline has been lowered;
- Reinstatement of the proposed Pipeline corridor, which will include restoration of original land contours as closely as possible, except grading of slopes at the Graphova Gap to manage slope stability;
- Dedicated mobile plant and refuelling areas. Fuel storage tanks will be double-walled. Secondary containment by bunding will surround the tanks;
- Provision of water storage facilities so that seasonal constraints on abstraction of groundwater at Sukko can be accommodated;
- Provision of wastewater collection systems and offsite disposal by licensed waste management operators;
- Chemical storage areas, which will be constructed on hardstanding with bunding; and
- Benching or grading along trench to enable safe working.

8.6.1.2 Impact Assessment Criteria

Receptors

A summary of the most sensitive soil, groundwater and surface water receptors is provided below.

Table 8.12 presents a summary of the identified receptors together with the respective sensitivity ranking. The justification for these sensitivity levels is presented in subsequent sections of this chapter.

<td>High*</td>
</tr>
</tbody>
</table>

* Human health sensitivity was not calculated based on the criteria given in this chapter. It is assumed that human health is highly sensitive to contamination impacts from soil, groundwater and surface water.

Soil and water receptors cannot be considered in isolation as they are interdependent; for example:

- Groundwater and surface water may experience secondary impacts associated with primary impacts to soils;
- Surface waters may experience secondary impacts associated with primary impacts to groundwater; and
- Soil and groundwater may experience secondary impacts associated with primary impacts to surface water.

Humans may experience secondary impacts associated with primary impacts to groundwater or surface water that subsequently affect abstractions. Note that where substances measured in water meet the respective drinking water standards, the health of existing or potential abstractors is not considered to be at significant risk.
Ecological receptors may experience secondary impacts associated with primary impacts on soil or water. The impacts to ecological receptors are assessed in Chapter 11 Terrestrial Ecology.

Pathways

Pathways are the means by which an activity can affect a receptor. In some cases this may be a physical migration pathway, such as a movement of contamination through a drain connecting two water features, or it may be the inherent nature of the activity itself; for example, excavation of soil will have a physical impact on the soil. For the purpose of this assessment some activities (such as excavation) are considered as an activity and a pathway.

Only where an activity, a pathway and receptor are present can an impact occur. The pathways considered in the ESIA process are summarised below:

- Physical disturbance of soils;
- Erosion and transport of soils by surface run-off;
- Changes to groundwater levels, for example, by forming lower permeability barriers or higher permeability preferential pathways;
- Groundwater and surface water interaction;
- Run-off into surface water;
- Movement of sediment within surface watercourses;
- Deposition of sediment onto soils adjacent to watercourses during flood events;
- Direct release of contaminants to soil and surface water;
- Leaching of contaminants from soils into groundwater;
- Migration of contaminants in groundwater;
- Migration of contaminants (in water and/or sediment) in surface water; and
- Ingestion, dermal contact and inhalation of contaminants in soil and sediment by construction workers.

Receptor Sensitivity

A series of impact significance criteria were developed to assess potential impacts on soil, water and sediment based on the general methodology outlined in Chapter 3 Impact Assessment Methodology, on professional judgement and experience, Good International Industry Practice (GIIP), and on the applicable Project standards and regulations.

The sensitivity of a soil or water receptor is a reflection of how vulnerable that receptor is to changes in chemical or physical attributes. The less sensitive receptors are those that are more resilient (less vulnerable) to change.

The concept of sensitivity also considers receptor value by capturing how important the receptors are to users of the environment (e.g. sustaining of ecosystems and humans via ecosystem services).
Sensitivity assessment criteria have been developed, using four categories of high, moderate, low and negligible.

Where the value and vulnerability assumptions are markedly different for an individual receptor, the more conservative category has been adopted.

**Soil Receptor Sensitivity**

Receptor sensitivity of soils is primarily related to the geochemical nature of the soils and the hydrological and nutrient cycling process of which they are a part (e.g. whether the soils are prone to erosion, fertility of soils, etc.). Similarly, the sensitivity depends on land-uses and ecosystems present. Soil sensitivity is also related to the presence of contaminants in the soil. This chapter focuses on the impacts to the soil baseline conditions. The associated risks to human health from baseline soil characteristics have also been assessed, as a link between humans and unknown soil contamination could be introduced by the Project.

The associated potential impacts of soil as a pathway upon land usage, ecology and ecosystems services are assessed in detail in the relevant chapters of this ESIA Report, specifically **Chapter 11 Terrestrial Ecology, Chapter 13 Landscape and Visual** and **Chapter 17 Ecosystem Services**.

Table 8.13 presents the receptor sensitivity criteria adopted for soils. In the absence of defined national guidance, the definitions for sensitivity criteria were informed by the GIIP US Guidelines for Soil Quality Assessment in Conservation Planning (United States Department of Agriculture) (Ref. 8.32).

**Table 8.13 Soil Receptor Sensitivity**

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Highly vulnerable to physical disturbance, structurally prone to compaction or erosion, and taking &gt;10 years to recover. High leachable and amenable to contamination. The soil provides a substrate that has the physical qualities and/or degree of productivity to support the development of important (in terms of nature conservation or concentration of biomass) and/or indigenous species of flora and fauna. The soil is intrinsically linked to the hydrological cycle; water is fundamental to its structure; and the soil plays a key ecosystem role in water regulation.</td>
</tr>
</tbody>
</table>

Continued...
<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Moderate</td>
<td>Vulnerable to physical disturbance but able to recover by mitigation measures within a period of 10 years. Moderately leachable. The soil provides a substrate that has the physical qualities and degree of productivity to support the development of species of flora and fauna in some abundance and levels of diversity. The soil has some capacity for water retention and regulation and plays some role in the hydrological cycle in terms of a degree of water regulation and as a substrate for channelling run-off.</td>
</tr>
<tr>
<td>Low</td>
<td>Resilient to physical disturbance and/or impermeable to contamination. The soil constitutes no particular favourable substrate for the development of floral habitats, invertebrates and other fauna. The soil plays little or no role in the hydrological cycle or regulation of water.</td>
</tr>
<tr>
<td>Negligible</td>
<td>This category is included in Chapter 3 Impact Assessment Methodology but is considered not applicable to soil quality.</td>
</tr>
</tbody>
</table>

Soils used for existing agricultural purposes, predominantly arenosols and abrazems/regosols, are a moderate sensitivity receptor due to their importance to local land users, although they may be resilient to physical disturbance from construction activities. The soils provide a substrate that has the physical qualities and/or degree of productivity to support agricultural development.

Phaeozem soils are a high sensitivity receptor. These soils are soft and are structurally prone to compaction or erosion, and prone to contamination through surface spills. Subsequently, they have a low resilience to impacts, and do not readily return to their natural state. It is also noted that phaeozem soils have a high water absorption capacity and play a key role in water regulation.

Fluvisols are a high sensitivity receptor as they play a role in the hydrological cycle and support the highly sensitive Nikolski’s tortoise (refer to Chapter 11 Terrestrial Ecology).

Within the Study Area, cambisols are only present above the microtunnel route and anthropogenic soils are locally present above the microtunnel route and beneath the access road route. Neither soil type is important for agriculture. These soils are low sensitivity receptors.

Existing unstable geomorphic features (Chapter 7 Physical and Geophysical Environment) are also a high sensitivity receptor. As active geomorphological features (erosion gullies, landslides and floodplains, etc.) typically already involve processes of physical disturbance to soils, they will continue to be highly vulnerable to further physical disturbance from activities associated with the Project.
**Human Receptor Sensitivity**

Construction workers are a high sensitivity receptor. As mentioned in Table 8.12, human health sensitivity was not calculated based on the criteria in this chapter; humans are considered highly sensitive to contamination from soil, groundwater and surface water.

**Groundwater Receptor Sensitivity**

The sensitivity of a groundwater body (the receptor) is typically based on three aspects: chemical quality, quantity and use of the groundwater resource. For example, a groundwater body may be valuable as a source of drinking water or as an integral part of a groundwater dependent ecosystem.

Table 8.14 presents the criteria used to classify groundwater receptor sensitivity based on the quantity and/or use of the resource, using the categories high, moderate, low, and negligible. It is noted that, based on the groundwater data currently available (Section 8.4.4), for conservatism the groundwater has been assumed to be a potential potable resource and to meet chemical quality criteria for potential potable use.

**Table 8.14 Groundwater Receptor Sensitivity**

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>

<tr>
<td>Negligible</td>
<td>Aquifer with negligible vulnerability and resource availability.</td>
</tr>
</tbody>
</table>
The groundwater receptors within the Study Area are the shallow superficial aquifers, and the underlying carbonate aquifer (Chapter 7 Physical and Geophysical Environment).

The aquifers are potentially potable water resources despite oil products being detected.

The superficial aquifer is of moderate sensitivity because the aquifer is vulnerable to pollution, the aquifer is relatively thin and thus vulnerable to changes in the flow regime, and the aquifer is expected to be in hydraulic connection with surface water, and in place, the deeper carbonate aquifer.

The sensitivity of the carbonate aquifer is moderate as it has the potential to be productive but is not currently exploited for the supply of its water within the Study Area. Elsewhere in the region, such as at Sukko, the bedrock aquifer is utilised for water supply. The carbonate aquifer may feed surface watercourses and the shallow alluvial aquifer via springs.

Mesophilic forest is present in the river valleys. The habitat is located adjacent to ephemeral watercourses; when surface water is absent in dry weather, groundwater will be of greater importance to this habitat. Springs also contribute towards the aquatic ecology associated with the watercourses. Fish and invertebrate species have been identified as being present in the watercourses when flowing. The sensitivity of the mesophilic forest habitat and the aquatic ecology within the watercourses, and the potential impacts on these ecological receptors due to the Project are assessed in Chapter 11 Terrestrial Ecology.

The groundwater abstraction for the Russkaya compressor station has negligible sensitivity because the Project does not lie within the designated sanitary protection zone for this abstraction (Ref. 8.3).

The source aquifer from which the Sukko wells abstract water has seasonal restrictions on its use and for this reason this groundwater resource is of high sensitivity.

**Surface Water Receptor Sensitivity**

The surface water receptors comprise the surface water bodies. This includes both the water and the stream bed sediments. The quality and abundance of water resources affects a wide variety of ecological habitats and ecosystem services. This section focuses primarily on the impacts to the surface water body baseline conditions. Associated potential impacts on ecological and anthropological systems are assessed, where appropriate, in the relevant chapters of this ESIA Report including Chapter 11 Terrestrial Ecology.

However, as there are secondary impacts associated with changes to the baseline conditions, these need to be considered in assessing the sensitivity of the primary surface water receptors. Table 8.15 presents a description of receptor sensitivity for surface water.
### Table 8.15 Surface Water Receptor Sensitivity

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>A water resource making up a vital component of a protected habitat or assemblage of species, which may have designated conservation status at an international and national scale. The water resource supports important (e.g. protected and/or large populations) of flora and fauna. The water resource is highly important and relied upon locally or is important at a regional or transboundary level for providing services.</td>
</tr>
<tr>
<td>Moderate</td>
<td>The water resource supports populations of flora and fauna. The water resource has a local importance in terms of providing services, but there is ample capacity and/or adequate opportunity for alternative sources.</td>
</tr>
<tr>
<td>Low</td>
<td>The water resource has limited or no role in supporting flora and fauna. The water resource has little or no role in terms of providing services for the local community.</td>
</tr>
<tr>
<td>Negligible</td>
<td>This category is considered non-applicable to surface water.</td>
</tr>
</tbody>
</table>

There are two surface water receptors within the Study Area:

- Shingar River; and
- An unnamed tributary of the Sukko River flowing through the Graphova Gap.

Each of these watercourses is within a 50 m wide sanitary protection zone (Ref. 8.20), which restricts the activities that take place in order to prevent contamination and silting of the water bodies. These protection zones help conserve the habitat for aquatic biological resources and other flora and fauna.

The watercourses are generally compliant (Ref. 8.1) according to the standards for amenity and general use of waters (Refs. 8.17, 8.18 and 8.19), although oil, nitrate and ammonia levels were exceeded (Section 8.5.1). Downstream of the landfall section, the watercourses flow through sensitive ecological habitats as described in **Chapter 11 Terrestrial Ecology**. The Graphova Gap will be crossed by the Pipeline (Figure 8.4). The watercourses are typically ephemeral. Flows are expected to vary seasonally and the watercourses are likely to only have substantial flow during and immediately after rainfall events. The watercourses support flora and fauna of low sensitivity (**Chapter 11 Terrestrial Ecology**). Both watercourses have been conservatively assessed as receptors of moderate sensitivity.

The surface water abstraction in the Study Area is located upstream of the Pipeline crossing in Graphova Gap (Ref. 8.4). The abstraction is unlicensed. The abstraction is used to irrigate the Kavkaz winery. This receptor is considered to have moderate sensitivity.
Mesophilic forest is present in the river valleys. The habitat is located adjacent to ephemeral watercourses that experience natural fluctuations in flow rate. Fish and invertebrate species have been identified as being present in the watercourses when flowing. The sensitivity of the mesophilic forest habitat and the aquatic ecology within the watercourses and the potential impacts on these ecological receptors due to the Project are assessed in **Chapter 11 Terrestrial Ecology**.

**Impact Magnitude Criteria**

The magnitude criteria consider size, likelihood and duration of the impact, both in terms of duration of the cause and the subsequent effect.

Impact magnitude assessment criteria have been developed, using four categories of high, moderate, low and negligible.

The determination of the overall impact magnitude rating has been determined on the basis of professional judgement and GIIP, considering all characteristics collectively rather than any one characteristic alone.

The likely frequency of the impact occurrence is also taken into account in assigning the overall impact grade. Impacts that would definitely occur are given a higher magnitude rating than impacts that might occur (e.g. removal of soil during earthworks compared with minor leaks and spills.)

**Soil Impact Magnitude**

For soils, the magnitude of a potential impact is determined predominantly in terms of the extent of loss of soil or loss of soil function. Typical activities and pathways for soil include:

- A direct change in soil volumes (e.g. excavation and disposal elsewhere);
- A direct change in soil area (e.g. covering soils with hardstanding);
- A direct change in the physical properties of soil (e.g. compaction);
- Changes in soil and water interactions (e.g. erosion or leaching);
- Increased potential for geomorphological instability or activation of existing geomorphologically unstable features; or
- Introduction of contaminants into the soil.

In particular, changes to chemistry of soils may lead to the applicable soil quality standards being exceeded.

Table 8.16 presents a description of the magnitude of change for soils using the classifications high, moderate, low and negligible.
Table 8.16 Soil Event Magnitude

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>The potential for soil quality and/or physical structure to be permanently impacted. The area affected by the activity is predicted to be large (&gt;10 ha).</td>
</tr>
<tr>
<td>Moderate</td>
<td>The impact on soil quality and condition may recover through natural processes and the impact will be medium term (several years). The area affected by the activity is predicted to be a medium extent (&gt;1 ha and &lt;10 ha)</td>
</tr>
<tr>
<td>Low</td>
<td>The impact on soil quality and condition is predicted to recover rapidly through natural processes and the duration of impact is short (limited to the Construction Phase). The area affected by the activity is predicted to be a minor extent (&lt;1 ha)</td>
</tr>
<tr>
<td>Negligible</td>
<td>No changes distinguishable from natural variability.</td>
</tr>
</tbody>
</table>

**Human Impact Magnitude**

If there is a linkage between soil-bound contamination and/or soil gas and construction workers the impact magnitude is considered to be high, otherwise the impact magnitude is negligible.

**Groundwater Impact Magnitude**

For groundwater systems, the magnitude of a potential impact is determined predominantly in terms of the extent of groundwater loss to the groundwater body in question. Losses to a groundwater resource can occur in terms of either quantity or quality. Typical activities and pathways for groundwater losses include:

- A direct change in the groundwater level causing deterioration of a groundwater resource (e.g. direct water abstraction);
- A reduction in groundwater and surface water interaction (e.g. tunnel providing barrier to groundwater flow to a river);
- Salt water intrusion for coastal receptors; or
- Introduction of contaminants into the groundwater body.

In particular, changes to water quality of groundwater bodies may lead to the applicable water quality standards for groundwater being exceeded.

Table 8.17 shows the criteria used to classify magnitude of impact.
Table 8.17 Groundwater Event Magnitude

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>There is a potential for water quality and/or quantity to be permanently impacted. There is a complete loss of integrity of a groundwater body or utilisation by receptors.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Water quality and condition is likely to recover through natural processes and the impact is predicted to be medium-term (several years). There is a loss in integrity of a groundwater body or a loss of part of the groundwater body.</td>
</tr>
<tr>
<td>Low</td>
<td>Water quality and condition is predicted to recover rapidly through natural processes and the duration of impact is short (limited to the Construction Phase). There is a temporary impact on receptor.</td>
</tr>
<tr>
<td>Negligible</td>
<td>Results in an impact on receptor but of insufficient magnitude to affect its use and/or integrity</td>
</tr>
</tbody>
</table>

Surface Water Impact Magnitude

For surface waters, the magnitude of a potential impact is determined predominantly in terms of the extent of changes to the flow regime or to water quality. Typical activities and pathways for surface water impacts include:

- A direct change in the flow regime causing deterioration of a surface water resource (e.g. change in flow, channel characteristics);
- A change in groundwater or surface water interaction (e.g. change in baseflow);
- A change in water availability for ecosystems or water supply; and
- Introduction of contaminants into the watercourse.

In particular, changes to surface water or stream bed sediment quality may lead to the applicable quality standards for watercourses being exceeded. Table 8.18 presents a description of the criteria used to classify magnitude of impact for surface water.
Table 8.18 Surface Water Impact Magnitude

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>The potential for natural recovery of water quality, quantity and/or physical disturbance through natural processes is limited and the impact is predicted to be long term (several years). Predicted to affect an entire watercourse downstream of the landfall section.</td>

8.6.2 Assessment of Potential Impacts: Construction and Pre-Commissioning Phase

8.6.2.1 Assessment of Potential Impacts (Pre-mitigation)

The impact magnitudes have been assessed against the impact magnitude criteria described above. This has been combined with the receptor sensitivity assessment using the matrix approach described in Chapter 3 Impact Assessment Methodology. The results are summarised in Table 8.19 to Table 8.21.

Soils

Soils in Study Area

The estimated area for temporary facilities and works during construction in the Study Area is 52.33 hectares (ha) as outlined in Chapter 5 Project Description. This includes construction areas and storage areas. All open-cut pipeline construction activities will be undertaken within a temporary construction corridor. The construction corridor will nominally be 120 m wide.

Storage and Use of Fuels, Chemicals and Wastes

During the Construction and Pre-Commissioning Phase, fuels and chemicals will be stored and used on site. The storage facilities proposed include embedded mitigation as described in Chapter 5 Project Description; for example the diesel and slurry storage tanks are double-
walled with leakage protection. Waste materials will be temporarily stored on site prior to disposal. Additionally, process wastewaters will be generated from mobile plant equipment and facilities operation, cleaning and maintenance. The handling of waste products, including hazardous materials (e.g. oil) is discussed in Chapter 18 Waste Management.

Potential contaminants include fuels, lubricants, cement, concrete, grout and slurry additives and metals. Contamination of the soil may result through accidental leaks or spills during construction (e.g. during refuelling or waste handling). Depending on the size and nature of the spillage, and the physical properties of the soil (including soil porosity, soil potential for pollutant sorption, and soil saturation), this could lead to contaminant migration and impacts at some distance from the site. The likelihood of leaks and spills occurring is higher in the main storage, refuelling and construction areas than along the Pipeline construction corridor. Refuelling of the fuel bowsers or vehicles within the construction sites will only be undertaken within designated refuelling areas. All fuel tanks will be located within secondary containment, which will form an impermeable bund, sufficient to contain at least 110% of the stored volume. The impact of a fuel spill on soil quality and condition may recover through natural processes and the impact is likely to be medium term. The likelihood of leaks and spills of grouts and slurry is primarily restricted to the construction area around the microtunnel entry shaft sites.

Leaks and spills are a potential impact of moderate magnitude to the agricultural soils, phaeozem soils and fluvisols, resulting in **Moderate** significance impact for agricultural soils and **High** significance impact for the phaeozem and fluvisol soils. The potential impact on other soils in the Study Area is low magnitude given the limited areas of these soils within construction areas, giving a **Low** significance impact.

Accidental damage to existing utilities could occur during land clearance and earthworks. This may result in contamination of the soil. This is likely to be minor in extent and is a low magnitude, resulting in **Low** significance impact for agricultural soils, **Moderate** significance impact for the phaeozem and fluvisol soils and **Low** significance impact for cambisols and anthropogenic soils.

**Agricultural Soils and Phaeozem Soils**

**Land Clearance and Earthworks**

Temporary alterations to ground conditions during the construction period may occur as a result of the clearance of land for the access roads, temporary construction areas, trenching activities, landfall facilities and vehicle movements.

The removal of vegetation will expose bare soils to erosion and/or compaction by the movement of heavy machinery and vehicles. The release of soil particles into surface watercourses and general migration down slopes could occur as a result of erosional processes (particularly where soil stockpiles are present).

Earthworks and stockpiling of soils can lead to the mixing of different soil types, and also the changing of the soil structure. Such mixing can influence soil type and structure, which may influence ecosystems or agricultural usage. Similarly, mixing of excavated soil types can result in the contamination of previously clean soils by contaminated soils.
For the access roads (excluding the Graphova Gap crossing, which is discussed below) and landfall facilities, the impacts associated with land clearance and earthworks are medium extent and moderate magnitude impacts for agricultural soils and phaeozem soils as the areas are less than 10 ha and the impacts are reversible, resulting in Moderate significance for agricultural soils and High significance for phaeozem soils.

For the temporary construction areas and trenching corridor (excluding Graphova Gap crossing, which is discussed below), the impact magnitude for agricultural soils is high as the area is large and is more than 10 ha, giving a High significance, and the impact magnitude for phaeozem soils and fluvisols is moderate given the minor extent of impact involved, giving a High significance for phaeozem soils.

In the event that excavated spoil generated as part of pipeline trenching or excavations for the landfall facilities or microtunnel entry shafts is unable to be re-used as part of Project, removal of excess spoil may be required. It is estimated that up to 15,000 m³ of surplus spoil will be left over from the installation of the four pipelines. Any surplus or unsuitable backfilling material (such as inert waste) will be removed from site and disposed of at an approved waste handling facility. The handling of waste materials is discussed in Chapter 18 Waste Management. The potential loss of soil from the Project Area as a result of this is of minor extent and an impact of low magnitude and Low significance.

**Microtunnelling**

In order to construct the Pipeline through the sea cliff, 1.4 km of the Pipeline will be housed in microtunnels. The tunnelling has the potential to introduce contaminating materials to soil, including grouts, slurries and lubricants, particularly near the entry shafts. Uncontrolled ingress of slurry or grout into the subsurface could occur during the microtunnelling works. This is most likely to affect the soil in the vicinity of the entry shafts as the majority of the tunnelling is within bedrock. However, slurry or grout may migrate locally from bedrock into the overlying soils via fractures and fissure zones. Given the minor extent, the potential impacts are of low magnitude and Low significance.

**Hydro-testing**

Hydro-testing will be undertaken as part of the pipeline integrity checks post-construction. Therefore, there is a possibility that pipeline sections with poor seals may be identified. Leakage may occur in these areas or the worst-case scenario would be uncontrolled discharge of the test waters into the subsurface may occur temporarily. During the hydro-testing, the test water may contain increasing concentrations of suspended sediment including metal particulates. Other contaminants such as hydrocarbons may also be present. Depending on the location of the leaks, this could permit test water to infiltrate through the soil, potentially contaminating soil. The effects are expected to be minor in extent and the Pipeline will be below the topsoil. The potential impact has low magnitude and Moderate significance.
Fluvisols

Land Clearance and Earthworks

Land clearance and earthworks construction, particularly for the access roads and the microtunnelling construction platform, may cause increased potential for erosion and compaction and may cause changes to soil properties. The impact magnitude is moderate given their minor extent and the significance for the fluvisols is High.

Open-cut Trench Crossing at Graphova Gap

The landfall section of the Pipeline to the east of the microtunnels will be constructed using open-cut techniques. The Pipeline will cross the Graphova Gap, through which a tributary of the Sukko River flows. The watercourse at this point is ephemeral, i.e. flow rates vary in relation to rainfall events. During the summer, the flows are typically low and the watercourses can be dry during low rainfall periods. Additional baseflow is provided by springs, but these are anticipated to also vary seasonally and in response to rainfall events.

For each of the four pipelines crossing the gap, a dedicated trench will be excavated perpendicular to the watercourse, such that the top of pipelines will be approximately 1.5 to 2 m below the bed of the watercourse. The Pipeline route has been locally deepened as a design control measure to reduce the risk of scour or erosion during flood events. The bottom of the trench will be approximately 2 to 3 m wide, with side slopes of approximately 45 degrees. Excavation of the pipeline trenches can be performed using standard hydraulic excavators and the Pipeline will be installed conventionally using standard pipe-laying equipment. During installation some pipe sections will undergo cold bending to ensure the Pipeline follows the contours of the watercourse crossing. After installation of the pipelines in the trench, protective measures will be installed as a design control measure to prevent possible flash floods from eroding the bed of the watercourse and exposing the external coating of the Pipeline. This protection can be achieved by installing a pre-cast concrete slab (approximately 1.2 m wide and 0.15 m thick) and suitable engineering backfill, i.e. graded material with rock fill (e.g. cobbles and boulders) on top of the Pipeline to prevent erosion, prior to backfilling. Following backfilling, the crossing will be reinstated, with banks rebuilt and seeded, or where additional stability is required, covered with a temporary geo-textile material or soil filled sacks where practicable. The modified slope angles created to aid slope stability during construction will be retained permanently post-reinstatement. All temporary works will then be removed.

Impacts on soils could include increased susceptibility to erosion due to vegetation clearance, the displacement of soils from the trenching process and the excavation and grading of the construction corridor due to the locally steep terrain, temporary stockpiling and storing of soil. The impact magnitudes for fluvisols taking into account the design controls are moderate given the works are localised but the effects may be medium term, giving a High significance.
Other Terrestrial Soils in Landfall Section (Cambisols and Anthropogenic Soils)

Land Clearance and Earthworks

Land clearance and earthworks during access road construction may cause increased potential for erosion and compaction and may cause changes to soil properties. The impact magnitudes and significance for the other soils in the Study Area are Low given their minor extent.

Geomorphologically Unstable Features

Impacts relating to ground instability are most likely to arise in areas of steep topography and where ground instability is already present due to natural weathering processes.

Land Clearance and Earthworks

Earthworks (including vegetation clearance, grading, soil stripping, trenching, and road access construction), stockpiles of excess spoil, construction of the land facilities and microtunnel entry shaft site have the potential to cause ground instability on slopes (either natural or man-made). This could lead to slope instability, associated ground subsidence and the formation of slope erosion features. Depending on the nature of the soil instability and ground movement, this could cause soil stability impacts that may extend over several years. The region is naturally subject to mudflows following intense rainfall events and materials from unstable slopes may be transported downstream during storm events. Ground instability of geomorphologically unstable features after the design controls are taken into account are of negligible magnitude giving a Low significance impact.

Open-cut Trench Crossing at Graphova Gap

As far as possible, the pipeline river crossing design at Graphova Gap takes the local topography into account to help manage ground instability risks. Ground instability of geomorphologically unstable features after the design controls are taken into account are of negligible magnitude giving a Low significance impact.

Microtunnelling

Microtunnelling beneath the Shingar River has reduced the likelihood of ground instability being caused by this aspect of the Project in the Shingar River valley and where the Pipeline crosses the coastal cliffs. Ground instability of geomorphologically unstable features after the design controls are taken into account are of negligible magnitude giving a Low significance impact.

Hydro-Testing

Potential leaks of water during hydro-testing could influence slope stability in areas of steeper terrain, predominantly associated with the valley sides. The effects are expected to be minor in extent and therefore the impact magnitude is low. The potential impact is of Moderate significance.
Human Health

Construction Workers

Elevated concentrations of contaminants that exceed published standards are known to occur in the soil within the Study Area (refer to the baseline in Section 8.5.1), albeit at comparatively low levels. The contaminants locally present in the soil may be harmful to human health under certain exposure scenarios. Contaminant concentrations in the soils appear to be highest in agricultural areas, at the watercourse crossings and near existing roads. Deposits of waste materials have been identified locally, including a ditch infilled with demolition materials that may contain asbestos. In addition to the known areas of contamination, the possibility exists that the Project may encounter currently unidentified, localised pockets of soil contamination, which may be disturbed by the earthworks. These may relate to past land use or uncontrolled waste disposal. However, the likelihood of encountering extensive unidentified contamination is relatively low given the current land uses in the Study Area.

Accidental leaks and spills during the works may also cause soil contamination (as discussed above).

Contaminated soil may affect construction workers through being inadvertently ingested or inhaled or through dermal contact. On the basis of the available information, the potential impact on human health before mitigation is of High significance given humans are a high sensitivity receptor and the magnitude is high due to a potential pollutant linkage being present between soil contaminants and humans.

Groundwater

Groundwater in Study Area

Potential impacts to the groundwater are likely to arise primarily in the Construction and Pre-Commissioning Phase through potential contamination from spills and leaks and potential disturbance of the flow regime during trenching and microtunnelling.

Storage and Use of Fuels, Chemicals and Wastes

During the Construction and Pre-Commissioning Phase, fuels and chemicals will be stored and used on site. The storage facilities proposed include embedded mitigation as described in Chapter 5 Project Description; for example the diesel and slurry storage tanks will have appropriate secondary containment for leakage protection. Waste materials will be temporarily stored on site prior to disposal. Additionally, process wastewaters will be generated from mobile plant equipment and facilities operation, cleaning and maintenance. Potential pollutants include fuels, lubricants, cement, concrete, grout and slurry additives and metals.

Construction workforce sewage and domestic wastewater will be generated. This includes wastewaters associated with ablution facilities, medical centres, showers, kitchens and other sewerage water mixed with drained water. The quantity of sewage and domestic wastewater produced depends on the number of workers present on onshore construction sites at any one time. All domestic wastewater shall be collected and tankered off-site to an appropriate waste
treatment facility. Anticipated wastewater volumes and planned storage and disposal are further discussed in Chapter 18 Waste Management.

Accidental release of pollutants to groundwater may occur due to leaks or spills. Leaks and spills may contaminate the groundwater, either directly through infiltration and migration of wastewaters or liquid wastes, or indirectly by leaching of soil contamination. The removal of topsoil is likely to increase groundwater vulnerability. If the trench or excavation has intercepted groundwater, then the vulnerability of the groundwater to leaks and spills will be increased. The likelihood of leaks and spills occurring is likely to be higher in the main storage, refuelling and construction areas than along the main pipeline permanent RoW.

The majority of leaks and spills are likely to be relatively small in volume. Groundwater quality may be locally affected but is expected to gradually recover through natural attenuation over the medium term. The potential impact on groundwater quality associated with accidental leaks and spills is of moderate magnitude and Moderate significance for the aquifers in the Study Area. The impacts to the abstractions at Russkaya and Sukko are of negligible magnitude given the distance from the site and are Not Significant.

Accidental damage to existing utilities may occur during land clearance and earthworks. This could result in contamination of the groundwater, either directly or via the soil or surface waters. This is likely to be minor in extent and is a low magnitude impact of Low significance for the Study Area.

Concentrations of benzo(a)pyrene, arsenic, total PCBs and copper slightly exceeding screening criteria have been identified is parts of the Study Area. Whilst these concentrations exceed the screening criteria they are unlikely to be impacting groundwater in the underlying aquifers. Given the agricultural land use in the Study Area the likelihood of significant areas of unidentified contamination is considered to be low.

Land clearance including the removal of vegetation, topsoil, hardstanding or existing structures may increase the potential for infiltration of precipitation through the soil, increasing leaching of soil contaminants to groundwater. However, for low concentrations of contaminants this will be off-set in part by natural attenuation processes.

Based on the available baseline data on soil contamination, this is of minor extent and low magnitude impact of Low significance for the Study Area.

**Land Clearance and Earthworks (Temporary Construction Areas)**

If the pipeline trenches (except at the Graphova Gap, which is discussed below), access roads or excavations at the landfall facilities intersect the water table, then groundwater control (maintaining groundwater levels to enable dry excavation) may be required. Given the trench and excavation depths of only 2.5 m, dewatering is unlikely to be required along the entire Pipeline corridor. Similarly, access road construction is only expected to extend below the water table in the cuttings. However, locally there may be a requirement for groundwater control during construction. This may involve dewatering abstractions. The impacts will be temporary and recovery is expected to be rapid. The impact upon groundwater flows within the superficial and bedrock aquifers is low magnitude and Low significance.
Open-cut Trench Crossing at Graphova Gap

The open-cut trench crossing the watercourse at Graphova Gap is likely to intersect the water table in the alluvial aquifer; given the bedrock is locally exposed in the valleys the trench crossing may also intersect groundwater within the carbonate aquifer. Groundwater control (maintaining groundwater levels to enable dry excavation) is likely to be required. This may involve dewatering abstractions. The impact upon groundwater flows within the alluvial aquifer is low magnitude and Moderate significance as the impacts will be temporary and recovery is expected to be rapid. The degree of hydraulic connection between the superficial and carbonate aquifers is likely to be greatest in the valley bottom. However, given the trench depths compared with the aquifer thickness, the potential impact to the carbonate aquifer is anticipated to be negligible magnitude and Not Significant.

Microtunnelling

The tunnel entry shafts may intersect the water table. Groundwater control (maintaining groundwater levels to enable dry excavation) may be required. The shaft walls will act as a local barrier. Dewatering may also be required to manage groundwater during the excavation of the shafts. Any change in water level that occurs in response to dewatering will be temporary and recovery is expected to be rapid. The impact upon groundwater flows within the superficial aquifer is of negligible magnitude and Not Significant given the presence of the shaft walls. The impact on the carbonate aquifer is conservatively assessed to be low magnitude and Moderate significance; if dewatering is not required then this would drop to negligible and low respectively.

The tunnel is within the carbonate aquifer. The tunnelling itself is not expected to require groundwater control when below the water table as groundwater ingress will be controlled by operating the TBM in closed mode, which maintains a pressure system to actively support the tunnel face. Injection of grout into the formation will control groundwater ingress further. The impact on the flow regime in the carbonate aquifer during tunnelling taking into account the planned design controls is consequently of negligible magnitude and Not Significant as no changes to the groundwater flow regime are expected.

Tunnelling has the potential to introduce contaminating materials directly into groundwater in the form of lubricants and bentonite slurry. The volumes of lubricants that might enter groundwater accidentally during operation of the TBMs are expected to be low. Bentonite slurry* will be used to help stabilise the tunnels during excavation. Slurry may contain various additives to aid the tunnelling operations and some additives may contain hazardous chemicals. Under normal operating conditions, the slurry will form a filter cake around the edge of the tunnel excavation. This will help reduce losses of slurry into the surrounding ground. Where the microtunnels intersect fracture or fissure zones, slurry may be lost along individual fractures. Fracture zones may form preferential pathways linking to the alluvial aquifer or surface water features. Given the absence of known karstic features (Ref. 8.1), the distance slurry may travel along fractures is likely to be of the order of a few metres. Groundwater quality immediately

---

* Slurry may sometimes be referred to as mud.
adjacent to the slurry may be temporarily influenced. The majority of the slurry will be removed during grouting and no permanent impact on groundwater quality associated with slurry is expected. The impacts on the superficial aquifer and carbonate aquifer are low magnitude and **Low** significance.

As the tunnelling machine exits the tunnel, seawater will enter the tunnel. The residual slurry on the tunnel walls will reduce the ingress of seawater into the aquifer. The hydraulic gradient and differences in water density are expected to reduce the inland migration of saline water migration within the aquifer via the tunnel. During grouting, seawater remaining within the tunnel annulus will be gradually displaced in a seaward direction (Chapter 5 Project Description) but any seawater that has entered the aquifer surrounding the annulus may remain. Through the prevailing hydraulic gradient and differences in water density the balance in fresh water and saline water within the aquifer is likely to return to its original condition over time and mitigate any long term impacts post-construction. The impacts on the alluvial aquifer are negligible magnitude, because the aquifer is above sea level, and are **Not Significant**. The impacts on the carbonate aquifer are low magnitude and **Low** significance.

Subsurface grouting around the tunnels will occur. The majority of the tunnels are within the carbonate aquifer. Where the microtunnels intersect fracture zones, grout may be lost along individual fractures. Fracture and fissure zones may form preferential pathways linking to the alluvial aquifer or surface water features. Given the absence of known karstic features (Ref. 8.1), the distance grout may travel, along fractures and fissures, is likely to be of the order of a few metres. As grout goes off, it can temporarily and locally influence the chemical quality of the adjacent groundwater, changing the pH and level of mineralisation. Metal concentrations may also rise. The presence of the grout may locally reduce aquifer permeability around the tunnels. The impacts of grouting are expected to be localised. The impacts of grouting on the superficial and carbonate aquifers are of low magnitude and **Low** significance.

**Hydro-Testing**

As described in Chapter 5 Project Description, the pipelines will be cleaned prior to hydro-testing. Seawater and debris (consisting of rust, coating and weld debris) will be captured in temporary onshore water storage (break) tanks. The collected seawater will be stored for a sufficient length of time to allow the debris to settle to the bottom. The debris will be removed from site and disposed of through an approved waste disposal company. The seawater will be temporarily stored and then pumped back into the pipelines during hydro-testing. If leakage or spills from the storage tank occurred, saline water could infiltrate into the subsurface and migrate down into the aquifer. However, the event will be short-lived and temporary, and dilution within the groundwater will occur. Particulate matter, for example metal particles, is unlikely to migrate far. The impacts to both the superficial and carbonate aquifers are of low magnitude and **Low** significance.

The hydro-testing of the pipelines will be undertaken using seawater. As described in Chapter 5 Project Description, the test water will be filtered seawater injected with an
oxygen scavenger (sodium bisulphite)\textsuperscript{10} to prevent internal corrosion of the Pipeline prior to
dewatering at an injection rate of 250 parts per million (ppm). In the event that the hydro-test
fails, the contractor will be required to detect the leak and then propose a repair method to
South Stream Transport. The repair method will depend on the nature and location of the leak.
The hydro-testing will then be repeated. Leakage from the Pipeline during a hydro-test failure
would infiltrate through the subsurface and enter groundwater. As the pipeline will be buried or
within a microtunnel, there may be minimal or no unsaturated zone present to attenuate any
pollutants present prior to reaching groundwater. However, the event will be of short duration
and dilution within groundwater will occur. Particulate matter, for example metal particles, is
unlikely to migrate far. Locally the salinity of the groundwater would temporarily increase but
then would gradually attenuate through natural processes such as dilution and dispersion. The
impacts to both the superficial and carbonate aquifers are moderate magnitude and \textbf{Moderate}
significance.

Following completion of the hydro-testing, the remaining seawater within the Pipeline will be
discharged to the sea and the Pipeline will be dewatered.

The hydro-testing of the landfall facilities will be undertaken using fresh water. Leakage during a
hydro-test failure at the landfall facilities would enter the site drainage system or infiltrate
through the subsurface and enter groundwater. However, the event will be of short duration and
dilution within groundwater will occur. Particulate matter, for example metal particles, is unlikely
to migrate far. The impacts to both the superficial and carbonate aquifers are low magnitude
and \textbf{Low} significance.

As described in \textbf{Chapter 5 Project Description}, it is possible that the filtered hydro-test
water from the first pipeline segments will be collected and temporarily stored on site in tanks
for use in hydro-testing the remaining three pipelines within the landfall facilities. If this is not
possible, the filtered water (containing no particulates or chemicals) will be discharged into a
sump constructed in an appropriate location within one of the temporary construction sites to
allow the water to infiltrate into the ground. As the water used in the hydro-testing of the
landfall facilities will be fresh and will be filtered, the impacts to both the superficial and
carbonate aquifers are of negligible magnitude and are \textbf{Not Significant}.

\textit{Water Abstraction}

Groundwater will be abstracted from the existing Ministry of Defence water supply in Sukko for
freshwater supply during construction. An estimated total volume of 37,000 m\textsuperscript{3} of freshwater is
required for the microtunnelling process and 500 m\textsuperscript{3} is required for hydro-testing of the landfall
facilities. In addition, it is estimated that up to 25 m\textsuperscript{3} per day freshwater will be used for
general construction activities (domestic usages, wheel washing etc.) during peak periods. The
water will be trucked to the construction areas from Sukko. There is a May to September
(inclusive) exclusion period when water cannot be abstracted from the existing source at Sukko.

\textsuperscript{10} Sodium Bisulphite is listed in OSPAR’s list of additives that Pose Little or No Risk to the environment (PLONOR).
OSPAR refers to the Oslo and Paris \textit{Conventions for the Protection of the marine Environment of the North-East Atlantic}
(OSPAR Conventions), 1992.
Due to this restriction, a large quantity of water (up to 10,000 m$^3$) may need to be stored at the western end of the Pipeline stringing area temporary construction site (adjacent to the microtunnel construction site). A much smaller quantity of water (no more than 800 m$^3$) may need to be stored at the landfall facilities site.

It is assumed that the licensed abstraction rate, including the seasonal exclusion period, has been set at a rate that will not cause the derogation, in terms of quality and quantity, of the aquifer resources, or of any other groundwater users within Sukko that utilise the same aquifer. The rate of abstraction during construction will not exceed the licensed rate and the impact to the groundwater resource is of negligible magnitude and Not Significant.

**Surface Waters**

**Surface Waters in Study Area**

Potential impacts to the surface watercourses are likely to arise primarily in the Construction and Pre-Commissioning Phase through potential spills and leaks, discharges and disturbance of soil and sediment leading to impacted surface water run-off.

**Storage and Use of Fuels, Chemicals and Wastes**

During the Construction and Pre-Commissioning Phase, fuels and chemicals will be stored and used on site. The storage facilities proposed include embedded mitigation as described in Chapter 5 Project Description; for example the diesel and slurry storage tanks are double-walled with leakage protection. Waste materials will be temporarily stored on site prior to disposal (Chapter 18 Waste Management). Additionally, process wastewaters will be generated from mobile plant equipment and facilities operation, cleaning and maintenance. Potential pollutants include fuels, lubricants, cement, concrete, grout, slurry additives and metals and waste waters (Chapter 18 Waste Management). As discussed for groundwater (Section 8.6.1.1), all domestic wastewaters are captured and transported by tanker to appropriate disposal sites.

Accidental release of pollutants to surface water may occur due to leaks or spills, either by entering watercourses directly, or through leaching from impacted soil to groundwater and subsequent migration in groundwater.

As described in Chapter 5 Project Description, stormwater drainage systems will be constructed at the landfall facilities site, the microtunnel construction site and the landfall construction site. The drainage systems will collect and manage surface water run-off. The drainage systems will incorporate measures to reduce suspended sediment concentrations and an oil separator and collection system.

The majority of leaks and spills are likely to be relatively small in volume. Long term potential impacts on surface waters are likely to be attenuated through natural processes such as dilution and degradation. Short term impacts may be more significant. Depending on the size and nature of the spillage, this could cause water quality or sediment quality impacts which affect elongated stretches of the watercourse and at some distance downstream from the site and it is therefore a potential impact of moderate magnitude and Moderate significance for the watercourses and the surface water abstractor.
Accidental damage to existing utilities may occur during land clearance and earthworks. This may result in contamination of the surface waters, either directly or via the soil or groundwater. This is likely to be temporary and limited in extent and is a low magnitude impact of Low significance for the watercourses and a moderate impact of Moderate significance for the assumed surface water abtractor.

Land Clearance and Earthworks

Temporary alterations to the surface water flow volumes and rates may occur as a result of trenching, land clearance, access road construction, development of the temporary construction areas and vehicle movements. It is likely that surface water run-off will temporarily increase in the temporary construction areas and permanently at the landfall facilities, due to the removal of vegetation, compaction of bare soils, and hardstanding at the landfall facility.

Increased sediment entering the surface watercourses could result from land clearance, excavation works and erosional processes (particularly on soil stockpiles and on access roads close to gullies until road drainage is established). The region is naturally subject to mudflows following intense rainfall events and materials from unstable slopes may be transported downstream during storm events. Increased sediment load may alter the flood capacity, increase water turbidity, and smother aquatic and riparian flora and fauna. The eroded sediment may also have a high nutrient or contaminant content which can contribute to the enrichment and contamination of downstream waters. Impacts on surface water quality will typically be of short duration (i.e. during and immediately after a storm event). It is considered that the watercourses will be able to recover relatively rapidly through natural processes; timescales are likely to be weeks to months depending on weather and the flow regime.

The impacts associated with land clearance and earthworks in the catchments of the Shingar River and the unnamed tributary in the Graphova Gap (except at the Graphova Gap crossing, which is discussed below) are likely to be medium term and of moderate magnitude and Moderate significance prior to mitigation for the watercourses and the assumed surface water abstraction.

Open-Cut Trench Crossing at Graphova Gap

Open cut trenching is proposed for the Graphova Gap pipeline crossing. Open cut trenching across the river will temporarily alter the flow during the installation works at the crossing and potentially result in flows during a flood event being diverted onto the surrounding floodplain. Given the nature of the topography at the crossing site with relatively steep valley sides, the impacts on the flow regime are likely to be local to the crossing. The crossing may also affect the sediment load and quality of the water at the crossing and along the downstream stretch of the watercourse. It is proposed that the construction be undertaken in dry weather when there is little to no flow in the ephemeral watercourse, which will reduce the likelihood of impacts. However, based on the worst case assumption that there are flows in the watercourse due to rainfall at the time of crossing construction, the impacts on the tributary in the Graphova Gap are medium term and is of moderate magnitude and Moderate significance. The assumed surface water abstraction is upstream and so should not be impacted.
Microtunnelling beneath the Shingar River

Microtunnelling is proposed for the Shingar River crossing. No direct disturbance of the Shingar River is expected as the microtunnels will be about 14 m below the base of the river. Indirect impacts may occur due to changes in groundwater quality resulting from slurry ingress and grouting during microtunnelling; these impacts are expected to be temporary and short lived. The impacts are of low magnitude and Low significance.

If failure of the slurry storage tanks occurred, slurry could directly enter the Shingar River via the tributary gully. If this happened, the consequences to water quality in the river could extend for a considerable distance downstream given the volumes of slurry being stored. However, the likelihood of this occurring is considered to be very low given the design controls in place, including bundled storage tanks with leakage protection (Chapter 5 Project Description). However, in the unlikely event that a major spill did occur, the impacts are of high magnitude and High significance.

Hydro-testing

As described in Chapter 5 Project Description, the pipelines will be cleaned prior to hydro-testing. Seawater and debris (consisting of rust, coating and weld debris) will be captured in temporary onshore water storage (break) tanks; the stored volume will be 100 m³. The collected seawater will be stored for a sufficient length of time to allow the debris to settle to the bottom. The debris will be removed from site and disposed of through an approved waste disposal company. The seawater will be temporarily stored and then pumped back into the pipelines during hydro-testing. If leakage or spills from the storage tank occurred, saline water could directly enter the Shingar River via run-off or indirectly via groundwater. However, the event will be short-lived and temporary, and dilution will occur. Particulate matter, for example metal particles, is unlikely to migrate far in the short-term but will enter stream bed sediments. The impacts to the Shingar River are of low magnitude and Low significance.

The hydro-testing will be undertaken using treated seawater; the volume of seawater used for hydro-testing will be 2,000 m³ per pipeline. As described in Chapter 5 Project Description, the test water will be filtered seawater injected with an oxygen scavenger (sodium bisulphite)¹¹ to prevent internal corrosion of the Pipeline prior to dewatering at an injection rate of 250 parts per million (ppm).

In the event that the hydro-test fails, the contractor will be required to detect the leak and then propose a repair method to South Stream Transport. The repair method will depend on the nature and location of the leak. The hydro-testing will then be repeated. Leakage during hydro-testing would be expected to infiltrate through the subsurface and may enter surface waters, usually via groundwater. This may temporarily affect surface water quality. The potential impacts in the tributary at the Graphova Gap may be medium term and are moderate magnitude and Moderate significance as leakage may enter surface waters directly at

¹¹ Sodium Bisulphite is listed in OSPAR’s list of additives that Pose Little or No Risk to the environment (PLONOR). OSPAR refers to the Oslo and Paris Conventions for the Protection of the marine Environment of the North-East Atlantic (OSPAR Conventions), 1992.
Graphova Gap as well as indirectly via groundwater. At the Shingar River, the Pipeline is in a tunnel 14 m beneath the river but the indirect pathway via groundwater from elsewhere in the catchment may remain. The potential impacts at the Shingar River are short lived and of low magnitude and **Low** significance.

Following completion of the hydro-testing, the remaining seawater within the pipeline will be discharged to the sea and the Pipeline will be dewatered.

The hydro-testing of the landfall facilities will be undertaken using fresh water. Leakage during a hydro-test failure at the landfall facilities would enter the site drainage system or infiltrate through the subsurface and enter groundwater. The water may then reach the tributary of Graphova Gap. However, the event will be of short duration and dilution will occur. Particulate matter, for example metal particles, is unlikely to migrate far in the short-term but in the unlikely event that particulate matter was to reach the watercourse it may enter stream bed sediments. The impacts to the tributary within the Graphova Gap are of low magnitude and **Low** significance.

### 8.6.2.2 Mitigation and Monitoring

Potential impacts from Project Activities to soil, groundwater, surface water and human health have been identified. The significance of these impacts has been assessed based on the sensitivity of each receptor and the expected magnitude of the potential impacts. The results of this assessment are presented in Table 8.19, Table 8.20 and Table 8.22.

Where impacts are identified as being significant, mitigation measures will be required to minimise the impacts or reduce the likelihood of an impact occurring. Appropriate mitigation measures, recommended to be implemented in addition to the design controls described in **Chapter 5 Project Description**, are presented in this section.

Note that many of the proposed mitigation measures aim to reduce the likelihood of impacts occurring, for example impacts associated with accidental leaks and spills. The pathways may still be present and the scale and duration of the effects may not necessarily be reduced. However, the likely frequency of the potential impacts will be reduced.

The mitigation measures will be controlled through the Russian Landfall Construction Management Plan (CMP), which will be developed as part of South Stream Transport’s Environmental and Social Management Plan (ESMP), outlined in **Chapter 22 Environmental and Social Management**. Monitoring will record how effective mitigation is and, if appropriate, may result in changes to the mitigation measures.

The construction contractor will ensure that site personnel are trained to be familiar with the current legislation and to comply with the requirements of the CMP. In particular, project staff will be made aware of:

- The relevant water and waste management requirements set out in the CMP and the contractors’ own Waste Management Plan to address handling, transportation and storage of waste and discharges of wastewater;
- The relevant contractor’s Spill Prevention and Response Plan for all chemicals, fuels and oils used during the Project; and
Chapter 8 Soils, Groundwater and Surface Water

- The Project Overarching Environmental and Social Monitoring Programme and Project Emergency Preparedness and Response Plan.

**Soils Mitigation (including Human Health)**

A number of the design controls described in Chapter 5 Project Description aim to reduce the risks to soils during construction (Section 8.6.1.1). Additional mitigation measures are presented below to address significant impacts.

To reduce the potential impact from spills and leaks compliance with the Russian Landfall CMP is required. The control measures to be adopted by the Project will be defined within a Spill Prevention and Response Plan which will be developed and maintained by each Project contractor.

Specific mitigation measures required to maintain soil quality during the Construction and Pre-Commissioning Phase include spillage prevention, bunding and restrictions near drains and watercourses, to avoid impacts. Materials will be stored, where practicable, with secondary containment and a full method statement to address construction risks and avoid impacts.

Activities near to drains and exposed sensitive soil areas will be controlled appropriately and in accordance with requirements in the Russian Landfall CMP to avoid adverse impacts.

Appropriate storage and handling protocols will be required for fuels and other chemicals used on site. Refuelling will only be undertaken in designated areas.

There will be dedicated plant and vehicle refuelling areas within the construction sites, which will be situated away from surface waters, groundwater and surface water drains. Secondary containment will be provided by forming an impermeable bund (i.e. a wall) around the refuelling area to provide containment in the event of a spill or rupture. Both storage tank and secondary bunding will be sufficient to contain at least 110% of the volume of fuel being stored.

Strict procedures will be followed when refuelling to minimise the risk of spills to the environment. All refuelling activities will be undertaken in line with requirements set out in the Russian Landfall CMP. The requirements of the Russian Landfall CMP need to be met by both South Stream Transport and the appointed contractors (and sub-contractors). Other fuels, oils and chemicals will be securely stored in clearly marked containers in a contained area to prevent pollution. It will also be ensured that spill kits, containing clean-up and absorbent materials etc. are stored in close proximity to the refuelling areas and with any mobile fuel bowers.

Chemicals and materials will be clearly labelled and Material Safety Data Sheets (MSDS) will be displayed at point of storage. Chemical and material storage areas will be well maintained, neat and tidy, with adequate inventory control. Chemical storage will be weather-proofed and on bunded hardstanding. The bunds and hardstanding will be impermeable and resistant to the materials being stored. Requirements for the chemical storage will be set out in the Russian Landfall CMP.
Spill kits shall be kept in accessible locations at all times during construction, and employees trained in their use and disposal. To reduce the potential impact from spills and leaks compliance with the Russian Landfall CMP is required. The control measures to be adopted by the Project will be defined within a Spill Prevention and Response Plan which will be developed and maintained by each Project contractor.

All bulk materials and wastes used in the construction activities with the potential to pollute will be stored within appropriate storage facilities (bunded, secondary containment) and procedures will be implemented for handling, storage, transport and transfer, in order to minimise the potential for leaks or spills.

The exact storage locations and dimensions of the water storage tanks will be finalised during the detailed design and will be agreed between the Contractor, South Stream Transport and the relevant local authorities.

To mitigate the potential risks to the health of construction workers, should soil contamination be identified, appropriate personal protection equipment will be used and hygiene facilities made available to all workers.

Mitigation measures that will increase the protection of existing soil quality and structure include:

- Spillage prevention, bunding and restrictions near artificial drains, sensitive soils (moderate/high sensitivity) and water bodies to minimise impact. Material will be stored away from sensitive soils and water bodies where possible, with secondary containment. Remediate as far as practicable any pollution of soil and water;
- Soil and ground disturbance will be restricted to the Pipeline construction corridor, the footprint of the temporary and permanent landfall facilities and construction of temporary and permanent access roads;
- Vehicle movements will be restricted to defined access roads and hardstanding areas as far as possible to minimise compaction of the soils and changes to surface water runoff rates and volumes;
- Area of ground excavation and exposed soils and spoil heaps will be limited as far as possible to reduce the potential for erosion and sediment run-off. Additionally, during heavy rainfall, potentially polluting activities will be limited, as appropriate;
- Limit quantity of excavated soil material as far as practical, prevention of contamination of stockpiled material through appropriate waste management (Chapter 18 Waste Management) and management of stored soils to prevent contamination and change of soil properties; increasing the potential for re-use of soils on site, and decreasing the need for removal of soils from the landfall section to landfill;
- Minimise loss of soil through the implementation of GIIP. Management of stored soils to prevent contamination and change of geotechnical properties. Increase the potential for re-use of soils on site, and decrease the need for removal of soils from the Project Area to landfill;
- Pre-construction surveys and GIIP will be used to reduce the risk of accidental damage to existing utilities that might cause contamination;
Construction measures in accordance with GIIP will be used to reduce the potential for soils mixing due to earthworks or erosion of soils. This will also reduce the risk of soil-based contaminant migration during earthworks;

Removal of anthropogenic materials from existing infilled ditch and disposal off-site to an appropriately licensed waste disposal facility. This material potentially contains asbestos. The risks to human health will be managed in accordance with GIIP during handling, storage and transport of the waste materials;

In the event that previously unidentified contamination is encountered during construction, works in the affected area will cease and appropriate steps will be taken in accordance with the Contractor's Contingency Plan, developed as part of the Contractor's Emergency Response Plan;

Areas disturbed during construction activities, will be rehabilitated in accordance with the Russian Landfall CMP. Construction site rehabilitation will be started as soon as practicable following construction to limit loss of soil through erosion;

Sediment and erosion controls (e.g. cut-off drains, swales, detention and retention basins, mesh fencing, sandbags etc.) will be implemented at construction sites to limit the loss of soil from the site;

Ensure silted water is appropriately managed prior to entering into any watercourses, attenuation measures to minimise soil erosion and impacts on water quality through potential disturbance of sediment;

Soil excavated from Pipeline trenches will be stored on the uphill side of the trench, where possible, until re-use or disposal;

No stockpiles will be located within 50 m of a watercourse. Stockpiles will generally be less than 2 m high. Stockpiles will not be located on unstable slopes. Stockpiles will be covered to prevent erosion as required. Run-off collection and management systems shall be used to remove pathways which enable the entrained sediment to enter watercourses;

Geotechnical engineering methods will be used if necessary to help stabilise temporary and permanent slopes at the landfall facilities. The potential for slope failures to occur will be minimised through design, management and monitoring;

Management of microtunnelling and grouting operations will reduce risk of uncontrolled movement of slurry or grout through subsurface;

To avoid the damage of phaeozem soils and instability of slopes, the potential for such failures to occur will be minimised through design, management and monitoring (in particular of excavation works). This includes the management of drainage systems, prevention of soil loading by restricting the height of stockpiles to 2 m, risk-assessed allocation of phaeozem soil and spoil storage areas by contractor, and monitoring of soils, water bodies, watercourses and drainage paths;

Appropriate construction management practices will reduce the probability of occurrence of slope instabilities, activation of landslides, collapsing and slope erosion. Use of geotechnical engineering measures to aid slope stability. Design, management and monitoring carried
out in line with the appropriate Construction Method Statements. Siting of stockpiles away from watercourses or unstable slopes;

• Appropriate tunnelling and grouting management practice to minimise loss of grout and slurry to the surrounding formation;

• Direct discharges from access road drains to watercourses will be avoided where sediment can collect within the drain and be discharged during high flows. In such cases discharge will be via a filter system (swale or silt trap). The receiving watercourses are to be identified and agreed with appropriate authorities. Discharge will generally be by gravity to avoid disturbance of settled silts in the cut-off trenches. All discharge points will be designed to minimise scour;

• Ditches and lateral drains alongside the construction works areas (including pipeline trench activities, foundations and access roads) will be sized to a 1 in 100 rainfall event;

• Mitigation measures will include the management of drainage systems, minimisation of soft soils loading, risk-assessed allocation of soil and spoil storage areas, monitoring of excavation and construction works and monitoring of watercourses and drainage paths;

• Surface water runoff control measures for earthworks will generally comprise infiltration and cut-off trenches, formed at suitable locations to intercept flows and reduce the velocity and sediment content. The gradient of the trenches will be as flat as possible to avoid high velocities during storm events;

• Throughout the lifespan of the Project periodic inspection and cleaning of blockages within the site drainage will be carried out;

• Areas disturbed during construction activities, will be rehabilitated. Construction site rehabilitation will be started as soon as practicable following construction to limit loss of soil through erosion;

• Reinstate soils and replant as soon as possible after construction and testing; and

• Safe working plans as set out in the Health, Safety, Security and Environment – Integrated Management System (HSSE-IMS).

Soils Investigation and Monitoring

Study Area:

• No additional pre-construction investigation or monitoring is required;

• During construction, a watching brief will be in place during earthworks. A remediation and contingency plan will be developed to deal with encountering soil contamination not identified during the pre-construction studies;

• Monitoring of soil quality will be undertaken during the Construction Phase. The monitoring shall include soil sampling at a small number of locations along the RoW. The sampling will be undertaken on an annual basis during construction and on completion of the land restoration along the RoW. The soil samples shall be analysed for basic soil properties such as pH and organic matter content, as well as measurement of nutrients and potential pollutants concentrations (including metals and petroleum hydrocarbons); and
Monitoring of the active geomorphological features will be undertaken during the Construction Phase. The monitoring shall include route inspections of active geomorphological features on a quarterly basis and on completion of the land restoration along the RoW. Additional monitoring will be undertaken following natural events that might affect geomorphological stability such as seismic events or flooding.

**Groundwater Mitigation**

In addition to the design controls (Section 8.6.1.1) and mitigation measures for soil outlined above (Section 8.6.2.2), the following mitigation measures will be adopted to minimise the potential for adverse impacts to groundwater:

- Sanitary and process wastewaters generated during construction will be stored in temporary facilities (mobile installations for wastewater treatment or septic tanks) and then regularly transported and disposed of in a nearby licensed facility for disposal of wastewater;
- Where dewatering is required all necessary discharge consents will be put in place. The quality of the water being discharged will be in accordance with the agreed discharge standards. If necessary, the abstracted water will be treated prior to discharge;
- All necessary discharge consents will be put in place prior to the disposal of the fresh water from the hydro-testing of the landfall facilities. The quality of the water being discharged will be in accordance with the agreed discharge standards;
- Groundwater control measures appropriate to the ground conditions will be used. Low permeability walls will be constructed for the tunnel entry shafts prior to dewatering;
- During heavy rainfall, potentially polluting activities such as dewatering of excavations is to be limited;
- Abstraction rates during any required dewatering of excavations will align with permitted agreements for any existing boreholes in use and in particular derogation of other water users will be avoided;
- Excavations should be backfilled with material with a similar permeability to the natural formation to prevent creating barriers or preferential pathways for water movement through the subsurface;
- The Drilling Management Plan will include measures to control groundwater ingress and minimise drilling fluid or grout loss from the trenchless option into surrounding aquifers. Avoid use of additives containing hazardous chemicals in drilling fluid or grout. Non hazardous chemicals will not exceed drinking water standards. All used additives will comply with PLONOR and therefore will be with low toxicity;
- If the ground conditions encountered during the excavation works indicate that there is the potential for the Pipeline at the Graphova Gap to create a barrier to groundwater flow such that baseflow to watercourses will be significantly affected, then drainage will be designed to allow groundwater to by-pass the obstruction to groundwater flow;
- Choice of anode material. Materials that are non-hazardous are preferable. Position the anodes above the water table if possible;
• Excavations should be backfilled with material with a similar permeability to the natural formation to prevent creating barriers or preferential pathways for water movement through the subsurface;
• If leaks or pipeline failure occurs during hydro-testing, the test will be stopped immediately to minimise potential infiltration of test water into the groundwater; and
• The leaching of grouts and drilling fluids will not cause pollution of groundwater and Russian standard SanPiN 2.1.4.1175-02 and Russian standard GN 2.1.5.1315-03 will be complied with.

As outlined in Chapter 5 Project Description, any construction activities in the Graphova Gap will be undertaken during dry weather as far as is practicable, when the groundwater levels and surface water flows are expected to be lower.

Groundwater Investigation and Monitoring

Groundwater will be monitored during and following the construction works. The monitoring programme will be agreed with the Russian Federation and shall adhere with national requirements. The monitoring programme will be included in South Stream Transport’s Environmental and Social Monitoring Programme discussed in Chapter 22 Environmental and Social Management.

Study Area:
• The groundwater monitoring network will include selected natural springs as well as monitoring boreholes adjacent to the microtunnels in the Shingar River valley. The monitoring will include measurement of groundwater levels (or flow rates from springs) plus the collection of groundwater samples. The samples shall be analysed for basic water chemistry, such as pH and electrical conductivity, as well as to assess potential pollutant concentrations (including metals and petroleum hydrocarbons);
• Pre-construction monitoring of groundwater in accordance with South Stream Transport’s Environmental and Social Monitoring Programme. This will include a monitoring round immediately prior to the start of construction to confirm there has been no significant change in groundwater quality since the baseline studies;
• Construction monitoring of groundwater in accordance with the Environmental and Social Monitoring Programme. Monitoring of groundwater levels and quality shall be undertaken at regular intervals during construction, with the frequency increased during microtunnelling and construction activities within the Graphova Gap;
• During construction a watching brief will be held during excavations. A remediation and contingency plan will be developed in the Contractor’s Emergency Response Plan to manage any groundwater contamination not identified during the pre-construction investigations; and
• Post-construction monitoring of groundwater in accordance with the Environmental and Social Monitoring Programme.
Surface Water Mitigation

In addition to the design controls (Section 8.6.1.1) and mitigation measures for soil and groundwater outlined above (Section 8.6.2.2), many of which are also relevant to potential surface water impacts, the following mitigation measures are also recommended to minimise the potential for adverse impacts to surface waters:

- Spillage prevention, bunding and restrictions near artificial drains, sensitive soils (moderate/high sensitivity) and water bodies to minimise impact. Material will be stored away from sensitive soils and water bodies where possible, with secondary containment. Remediate as far as practicable any pollution of soil and water;
- The timing of construction activities in the Project Area will be important in limiting the potential for adverse impacts to surface waters. Where possible, construction in the immediate vicinity of watercourses will be carried out during dry weather, when the nearby watercourses have low or no flow and surface water runoff will be minimal;
- Appropriate diversion channels, or alternatively over-pumping provision, will be incorporated during construction in the Project Area such that continuity of the stream flow will be maintained during the works in the event of low intensity rainfall events during construction;
- Silt fences and/or other suitable measures will be located along and adjacent to the Graphova Gap crossing, as required. Other mitigation measures such as entrapment matting will be used where necessary. In order to prevent direct unplanned discharge to watercourses, drainage pathways will be identified during construction works and silt fences, settlement ponds, sediment entrapment matting and straw bales installed as necessary;
- Natural drainage patterns, in particular in the vicinity of surface water crossings will, where necessary, be maintained. Natural flows will, where necessary, be maintained. Existing artificial drainage to be diverted maintaining gravity flows;
- At the Project Area direct discharge of surface run-off to watercourses will be avoided as far as possible. Surface water runoff control measures for earthworks will generally comprise infiltration and cut-off trenches, formed at suitable locations to intercept flows and reduce velocity and sediment content. Ditches and lateral drains alongside the construction works areas (including pipeline trench activities, foundations and access roads) will be appropriately sized through GIIP for design and construction. Drainage systems shall be generally designed to be gravity controlled to avoid disturbance of settled silts. Drainage systems will be aligned with natural drainage patterns;
- Surface run-off treatment systems will be implemented at the landfall facilities to control the quality of the surface run-off entering watercourses. The drainage systems for the landfall facilities and the microtunnel construction area will include stormwater treatment systems. The necessary consents will be in place prior to discharge commencing. The quality of the water being discharged will be in accordance with the discharge consent. The treatment standards will be aligned with national water quality standards (Table 8.3). Treatment of road and pipeline construction corridor stormwater will not be undertaken;
- All drainage discharge points will be designed to minimise scour;
Throughout the lifespan of the Project, periodic inspection and cleaning of blockages within the site drainage will be carried out. Limiting the area of ground to be excavated and the areas of exposed soils or spoil heaps will reduce the potential for erosion and sedimentation. Additionally, during heavy rainfall, potentially polluting activities such as dewatering of excavations is to be limited;

- The gradient of the pipeline trenches will be as flat as possible to avoid high velocities during storm events;
- Sediment and erosion controls will be implemented at construction sites to limit sediment in runoff;
- Road edge drains will be led away by ditches into drainage swales via settlement lagoons and small ponds away from the road edges so that runoff is controlled to prevent sediment entering local surface waters;
- Direct discharges from the landfall facilities drainage systems to watercourses will be avoided;
- No stockpiles will be stored within 50 m of any watercourses;
- Any stockpiles that are to be left for some time will be covered to prevent erosion and silt fences used to remove pathways which enable the entrained sediment to enter watercourses;
- Inspection and cleaning of pipe sections before installation will reduce the quantity of sediments and contaminants present in the dewatering and cleaning effluent, as well as from dewatering of the sites; and
- Collection and recycling of the drilling fluid and grout used in microtunnelling, which reduces water consumption.

Surface Water Investigation and Monitoring

Surface water will be monitored during and following the construction works. The monitoring programme will be agreed with the Russian Federation and shall adhere with national requirements. The monitoring programme is further discussed in Chapter 22 Environmental and Social Management.

Study Area:

- The monitoring network will comprise upstream and downstream locations on the Shingar River and the watercourse in the Graphova Gap. The monitoring will include measurement of surface water flows plus the collection of water and stream bed sediments samples. The water samples shall be analysed for basic chemistry, such as pH, electrical conductivity, dissolved oxygen and suspended solids, as well as to assess potential pollutant concentrations (including metals and petroleum hydrocarbons). The sediment samples shall be analysed for basic properties, such as pH, particle size distribution and organic matter content, as well as to assess potential pollutant concentrations (including metals and petroleum hydrocarbons);
- Pre-construction monitoring of surface water will be undertaken in accordance with Environmental and Social Monitoring Programme. This will include a monitoring round
immediately prior to the start of construction to confirm there has been no significant change in surface water or sediment quality since the baseline studies;

- The Environmental and Social Monitoring Programme includes construction monitoring of surface water;

- Monitoring of surface water will be undertaken during the Construction Phase in accordance with Environmental and Social Monitoring Programme. Monitoring of surface water flows and water quality shall be undertaken at regular intervals during construction, with the frequency increased during construction activities within or immediately adjacent to the watercourses; and

- During construction a watching brief will be held. A contingency plan will be developed in the Contractor’s Emergency Response Plan to manage surface water contamination not identified during the pre-construction investigations.

Post-construction monitoring of surface water in accordance with Environmental and Social Monitoring Programme.

### 8.6.2.3 Residual Impacts: Construction and Pre-Commissioning Phase

Table 8.19, Table 8.20 and Table 8.21 present a summary of the potential residual impact significance to soil and terrestrial sediment, groundwater and surface water arising from the Project following application of the identified mitigation measures (Section 8.6.2.2).

The assessment of the significance of residual impacts assumes full application and effectiveness of the mitigation measures.

#### Soils

The mitigation measures proposed reduce the significance of the residual impacts on soils and sediments to **Low**.

#### Groundwater

The mitigation measures proposed reduce the significance of the residual impacts on groundwater to being **Low** to **Not Significant**.

#### Surface Water

The mitigation measures proposed reduce the significance of the residual impacts on surface watercourses to being **Low** to **Not Significant**. The residual impact at the surface water abstractor is **Low**.

#### Human Health

The mitigation measures proposed reduce the significance of the residual impacts on humans to **Low**.

* Potential impact magnitude is high but likelihood of occurrence is very low.

Complete.
8.6.3  Assessment of Potential Impacts: Operational Phase

8.6.3.1  Assessment of Potential Impacts (Pre-mitigation)

The permanent RoW will be approximately 95 m wide (19 m either side of the centreline of the outermost pipelines) and 2.5 km long (0.1 km upstream and 2.4 km downstream of the landfall facilities) and will result in a permanent land take of approximately 23.75 ha. The permanent RoW will include an access track.

Operational activities associated with the Project are limited. Operation of the Project for the terrestrial part of the landfall section will involve routine inspections, maintenance activities and monitoring.

The Pipeline permanent RoW will be indicated by land and aerial markers. Warning signs to indicate the presence of the pipelines will also be erected at specific locations along the Pipeline route. Deep rooting trees or permanent crops will not be allowed to grow, however bushes and other shallow rooted vegetation will be allowed to grow naturally or will be planted. A track suitable for 4x4 vehicles only, will be present within the RoW for inspection purposes of the pipelines.

Maintenance activities will include the periodic clearing of certain vegetation from the permanent RoW. It is assumed that the vegetation clearance will be primarily through mechanical clearing. It is assumed that regular and widespread herbicide application will not be required for the required partial vegetation clearance as shallow vegetation will be allowed to grow. However, it is recognised that herbicide usage may be locally required on occasion.

The operation of vehicles and equipment to undertake these maintenance and inspection activities are seen as the key activities of relevance to soil, groundwater and surface water baseline conditions.

The impacts due to the presence of the Pipeline, tunnel, the Graphova Gap pipeline crossing and access roads, are presented under the Operational Phase assessment because these are considered to be impacts that arises as a result of operation and not as a result of construction activity.

Soils

There is the potential for soils around the landfall facilities, RoW and access roads to be contaminated through vehicle movements, spills and leaks. Typical contaminants include those associated with vehicle operations including hydrocarbons and heavy metals. There will be no discharges to soil of sanitary or process wastewater. The potential for contamination of soil at the landfall facility, RoW and access road is low magnitude and **Moderate** significance.

Soils within the permanent right of way (RoW) along the Pipeline route may be disturbed through the periodic clearance of vegetation and vehicle movements. Vegetation provides protection and stability to soils from erosive forces. Maintenance and permanent RoW clearance activities are not anticipated to require removal of all ground vegetation, and therefore soil disturbance will be limited. This impact is of low magnitude and **Moderate** significance.
The pipeline crossings at the Graphova Gap and the anode groundbed at the Landfall facilities are in areas with naturally unstable geomorphic features (Chapter 7 Physical and Geophysical Environment). Erosion during flood events can be a key natural mechanism triggering ground movements associated with these features. The presence of the Project infrastructure could influence stability but the effects are expected to be localised and can be managed through design controls implemented during the Construction Phase. The impact during the Operational Phase due to the on-going presence of the structures is of low magnitude and Moderate significance.

Groundwater

Groundwater quality may be affected by any accidental leaks or spills at the landfall facilities or during maintenance activities. The limited activity on site during the Operational Phase reduces the likelihood of spills occurring. Therefore, it is an impact of low magnitude and Moderate significance for the superficial and carbonate aquifer. Negligible impact is expected at the groundwater abstractions; this is Not Significant.

The buried pipes will pass under the Graphova Gap. The buried pipes may act as a barrier to groundwater flow in the superficial aquifer. Any impact on flows that did occur would be long term but spatially localised. However, given the design it is unlikely that the pipelines will create a complete barrier to groundwater flow. Therefore, it is an impact of low magnitude and Low significance for the superficial aquifer. The impact on the carbonate aquifer is to be negligible magnitude and is Not Significant. No impact is expected at any of the abstractions.

The microtunnels may act as a barrier to groundwater flow. Any impact on flows that did occur would be long term but spatially localised. However, given the size of the tunnels relative to the aquifer geometry it is unlikely that the pipelines will create a complete barrier to groundwater flow. Therefore it is an impact of low magnitude and Low significance for the carbonate aquifer. The impact on the superficial aquifer is of negligible magnitude and Low significance. No impact is expected at any of the abstractions.

The anodes in the subsurface as part of the cathodic protection systems will gradually degrade, releasing metal ions into the subsurface, which will be leached and infiltrate into groundwater. The anodes are proposed to be titanium with mixed metal oxides. The rate of anode degradation is anticipated to be very slow (decades). Natural attenuation including dilution within the groundwater will reduce concentrations in groundwater within a relatively short distance from the anode bed. The calcined petroleum coke backfill around the anodes is considered effectively inert; no significant leaching of contaminants from the backfill into groundwater is expected. Some sorption of metal ions onto the coke may occur. Considering that the anodes are below the water table the impacts on both aquifers are of negligible magnitude and are Not Significant. No impact is expected at any of the abstractions.

Surface Water

Surface water quality may be affected by any accidental leaks or spills. The limited activity on site during the Operational Phase reduces the likelihood of spills occurring. The impact on water quality in both watercourses within the Study Area and at the assumed surface water abstraction is likely to be limited and of low magnitude and Moderate significance.
Periodic clearance of vegetation may lead to an increase in soil erosion and run-off rates. This may influence water quality and the flow regime. However, maintenance and permanent RoW clearance activities will not require removal of all ground vegetation, and soil disturbance will be limited. This impact is limited and of low magnitude and **Moderate** significance.

It is unlikely that the presence of the tunnels would affect natural groundwater baseflow such that the flow regime in the Shingar River is influenced. Thus the impact magnitude is assessed as negligible magnitude and **is Not Significant**.

Where the pipelines cross the Graphova Gap, they may behave as an obstruction and cause groundwater levels to change, which may lead to a change in baseflow to surface waters, especially during the winter months. However, given the design, including permeable rock fill, it is unlikely that the pipeline trenches will create a complete barrier to groundwater flow. The impact for the watercourse is therefore low magnitude and **Low** significance. The impact on the surface water abstraction is negligible magnitude and is **Not Significant**.

As described in **Chapter 5 Project Description**, rock fill and a buried concrete slab will be used to help protect the Pipeline from scour and erosion during flood events. This will be designed not to erode significantly during typical flow events. However, during major flood events the backfill may be eroded. This would not naturally recover without maintenance works. The overall impact on the watercourse is therefore moderate magnitude and **Moderate** significance.

The presence of the rock fill will alter the nature of the local bed sediments over this stretch of the stream. Gradually, fine-grained sediment will infill the gaps between the rock fill and the stream bed will return to a more natural condition. The impact will be limited in spatial extent and will gradually recover through natural processes. The impact on the watercourse is therefore low magnitude and **Low** significance.

The access roads and landfall facilities will be static sites. Run-off from areas of hardstanding will be higher than from vegetated areas. Storm water run-off during wet weather events may capture minor volumes of contaminants (e.g. traces of oil and grease) and entrain sediments. However, the impacts of run-off on water quality will only occur during times of high flow (i.e. when water quality in the watercourses is naturally likely to be highly turbid and dilution factors will be high). The impact on the Shingar River is of negligible magnitude and **Not Significant**. The impact on surface waters in Graphova Gap and the surface water abstraction from surface run-off from the access road and landfall facilities is limited and of low magnitude and **Low** significance for the flow regime and of **Moderate** significance for water quality.

The anode groundbed in the landfall facilities is located in a natural run-off channel with evidence of natural erosion during rainfall events. Further downhill is a gully which is a tributary of the watercourse in Graphova Gap. During flood events, the backfill from the anode groundbed may be eroded by run-off. The calcined petroleum coke is inert and the groundbed is uphill from the main stream channel. However, the coke backfill may migrate further than rock-based sediment during flood events as it will be lighter. The impact on downstream water quality is limited and of low magnitude and **Low** significance.
Mitigation and Monitoring

Some of the effects of activities associated with the Operational Phase of the Project may impact on soil, groundwater and surface waters. The significance of these impacts has been assessed based on the sensitivity of each receptor and the expected magnitude of the potential impacts. The results of this assessment are presented in Table 8.22, Table 8.23 and Table 8.24.

Where significant impacts are identified, mitigation measures will be required to minimise the impacts or reduce the likelihood of an impact occurring. Appropriate mitigation measures are presented in this section.

The mitigation measures will be controlled through the ESMP for the Operational Phase. Monitoring will record how effective mitigation is and may result in changes to the mitigation measures.

Soils Mitigation

A number of the design controls described in Chapter 5 Project Description aim to reduce the risks to soils during the Operational Phase (Section 8.6.1.1).

Mitigation measures are recommended to further reduce the risk of leaks and spills occurring. Compliance with the Emergency Response and Crisis Management Plan and requirements in the Russian Landfall CMP is required. In the event of a leak or spill occurring, the speed of response to the incident is a key factor in determining the magnitude of the resultant impacts.

Appropriate storage and handling protocols will be required for fuels and other chemicals used on site. Refuelling will only be undertaken in designated areas. Activities near to watercourses and drains and exposed soil areas will be controlled. All bulk materials or wastes stored on site will be within appropriate storage facilities and procedures will be implemented for handling, storage, transport and transfer to minimise the potential for leaks or spills.

Further specific mitigation measures that will be implemented to protect the existing soil quality and structure include:

- Restriction of construction activities to the Pipeline RoW, the footprint of the permanent landfall facilities, and permanent access roads;
- Vehicle movements will be restricted to defined access tracks and hardstanding areas;
- Sediment and erosion controls (e.g. cut-off drains, swales, detention and retention basins, mesh fencing and sandbags etc.) will be implemented at all maintenance sites to limit the loss of soil from the site;
- Sediment and erosion controls, including appropriate drainage systems, will be routinely inspected and maintained to manage run-off and to limit the loss of soil from the site, in particular following vegetation clearance;
- Spillage prevention, bunding and restrictions near drains, sensitive soils and water bodies to avoid impacts. Material will be stored away from sensitive soils and water bodies where possible, with secondary containment and a full method statement to address construction risks and avoid impacts; and
• Ensure potential silted water is appropriately managed prior to entering into any watercourses, attenuation measures to minimise soil erosion and impacts on water quality through potential disturbance of sediments.

Soils Monitoring
• Monitoring of the active geomorphological features will be undertaken in accordance with Russian guidance in relation to 'Safety in emergency situations - Monitoring and predicting hazardous geological phenomena and processes - General requirements' (GOST R 22.1.06-99 and GOST R 22.1.08-99). The monitoring shall include route inspections of active geomorphological features; the frequency of monitoring shall be gradually reduced as stabilisation progresses but is expected to be at least every three years. Additional monitoring will be undertaken following natural events that might affect geomorphological stability such as seismic events or mudflows; and

• No ongoing monitoring of soil quality is required during the Operational Phase.

Groundwater Mitigation
In addition to the design controls (Section 8.6.1.1) and mitigation measures for soil outlined above (Section 8.6.2.2), the following mitigation measures are also recommended to be adopted to minimise the potential for adverse impacts:

• Sanitary wastewaters generated during Operational Phase will be safely stored in temporary facilities (mobile installations for wastewater treatment or septic tanks) and then regularly transported and disposed of in a nearby licensed facility for the disposal of wastewater;

• Choice of anode material. Materials that are non-hazardous are preferable. Position the anodes above the water table if possible;

• If there is the potential for the Pipeline to create a barrier to groundwater flow such that baseflows to Graphova Gap are significantly affected, then drainage will be designed and installed during construction to allow groundwater to by-pass the obstruction to groundwater flow; and

• Consultation with neighbouring abstractors as and when required.

Groundwater Monitoring
No ongoing groundwater monitoring is required during the Operational Phase.

Surface Water Mitigation
In addition to the design controls (Section 8.6.1.1) and mitigation measures for soil and groundwater outlined above (Section 8.6.2.2), many of which are relevant to potential surface water impacts, the following mitigation measures are also recommended to be adopted to minimise the potential for adverse impacts:

• The detailed design of the Graphova Gap pipeline and access road crossings will allow for maintaining natural flows. The access road crossing will be designed to avoid significant increase in flood risk downstream;
• Stormwater discharges from the landfall facilities will pass through a sand trap and filter, and an oil interceptor prior to discharge. The treatment standards will be aligned with required water quality standards prior to discharge of the stormwater into the environment;
• The anode groundbed will be microsited in relation to local terrain and the backfill and surfacing will be designed to reduce the potential for erosion by run-off;
• Throughout the lifespan of the Project, periodic inspection and cleaning of blockages within the site drainage will be carried out and detailed within a monitoring programme;
• Direct discharges from the landfall facilities drainage systems to watercourses will be avoided;
• Where possible, drainage of working areas will include routing of surface water to detention basins to settle out suspended solids before discharge to watercourses;
• Throughout the lifespan of the Project periodic inspection and cleaning of blockages within the site drainage will be carried out and detailed within a monitoring programme; and
• Inspection and reinstatement following major flood event.

**Surface Water Monitoring**

Surface water quality monitoring is required during the Operational Phase. Monitoring shall be undertaken periodically within the watercourse in the Graphova Gap to confirm the stormwater drainage systems at the landfall facility are operating as designed. This will include collection of upstream and downstream water samples. The monitoring scope and frequency will be in accordance with the agreed discharge consent for the stormwater drainage system. The water samples shall be analysed for basic chemistry, such as pH, electrical conductivity, dissolved oxygen and suspended solids, as well as to assess potential pollutant concentrations (including petroleum hydrocarbons).

### 8.6.3.3 Residual Impacts: Operational Phase

Table 8.22, Table 8.23 and Table 8.24 present a summary of the potential residual impacts to soil, groundwater and surface water respectively arising from the Project following application of the mitigation measures described in Section 8.6.2.2.

The assessment of the significance of residual impacts assumes full application and effectiveness of the mitigation measures.

**Soils**

The significance of the residual impacts on soils is **Low**.

**Groundwater**

The significance of the residual impacts on groundwater is **Not Significant to Low**.

**Surface Water**

The significance of the residual impacts on surface waters is **Not Significant to Low**.

8.6.4 Assessment of Potential Impacts: Decommissioning Phase

8.6.4.1 Introduction

The planned Project lifetime is 50 years, within which there may be changes to statutory decommissioning requirements, as well as advances in technology and knowledge. The eventual decommissioning requirements will be taken into account in the design stage by ensuring that a range of possible options will be available.

Decommissioning of the South Stream Offshore Pipeline will be carried out according to prevailing international and national legislation, regulations and good practice regarding environmental and other potential impacts.

At this stage in the Project the full extent of the decommissioning requirements is not known. If the trenched pipeline is removed, the impacts during decommissioning are expected to be broadly similar to those during construction. If the trenched pipeline is left in place, the potential impacts are likely to be reduced. It is assumed that it is probable that the pipelines within the microtunnels shall be decommissioned but will remain in situ.

Potential impacts to abstractions have not been assessed as it is unknown what, if any, abstractions may be present in the Study Area at the time of decommissioning.

8.6.4.2 Assessment of Potential Impacts (Pre-mitigation)

Soils

Potential impacts to soil during decommissioning will relate to the storage and use of fuels, chemical and waste, land clearance and earthworks, and the interactions between decommissioning workers and the soil.

Leaks and spills are a potential impact of medium extent and moderate magnitude to the agricultural soils, phaeozem soils and fluvisols, resulting in Moderate significance impact for agricultural soils and High significance impact for the phaeozem and fluvisol soils. The potential impact on other soils in the Study Area is low magnitude given the minor extent of these soils within the landfall section, giving a Low significance impact.

For the landfall facilities, the impacts associated with land clearance and earthworks are of moderate magnitude impacts for agricultural soils and phaeozem soils as the areas are medium in extent and less than 10 ha and the impacts are potentially reversible, resulting in Moderate significance for agricultural soils and High significance for phaeozem soils.

If the trenched pipeline has to be removed during decommissioning, then there will be impacts associated with land clearance and earthworks along the trenching corridor. The impact magnitude for agricultural soils is high as the area is large and more than 10 ha, giving a High significance, and the impact magnitude for phaeozem soils is moderate given the medium extent, giving a High significance for phaeozem soils. The impact magnitudes for fluvisols during the removal of the pipeline crossing at Graphova Gap are moderate given the works are
medium in extent and the soils are expected to gradually recover after reinstatement due to natural processes, giving a **High** significance.

Ground instability of geomorphologically unstable features are of moderate magnitude given the effects are likely to be minor in extent but of medium term, giving a **High** significance impact.

**Construction Workers**

The potential for contamination to be present in the soils will be reviewed prior to decommissioning. Contamination may be present locally due to current or future land use or illegal dumping.

Accidental leaks and spills during the decommissioning works may also cause soil contamination.

Contaminated soil may affect construction workers through being inadvertently ingested or inhaled or through dermal contact. For conservatism the potential impact on human health before mitigation is of high magnitude and **High** significance given humans are a high sensitivity receptor.

**Groundwater**

Potential impacts to the groundwater are likely to arise primarily in the Decommissioning Phase through potential contamination and disturbance of the flow regime during any excavations.

The majority of leaks and spills are likely to be relatively small in volume. Groundwater quality may be locally affected but is expected to gradually recover through natural attenuation and the impact will be medium term. The potential impact on groundwater quality associated with accidental leaks and spills is moderate magnitude and **Moderate** significance.

If the trenched pipeline is removed or any excavations are required during decommissioning of the landfall facilities, there is the potential for the excavations to intersect the water table, particularly at the Graphova Gap. The impact upon groundwater flows within the superficial aquifer is low magnitude and **Low** significance as the impacts will be temporary and recovery is expected to be rapid. Given the expected excavation depths, the potential impact to the carbonate aquifer is anticipated to be negligible magnitude and **Not Significant**.

The soil strip and removal of vegetation during land clearance and earthworks will have a low magnitude impact of **Low** significance.

**Surface Water**

Potential impacts to the surface watercourses are likely to arise primarily in the Decommissioning Phase through potential contamination and disturbance associated with construction site discharges, run-off and changes to local landforms.

The majority of leaks and spills are likely to be relatively small in volume. Depending on the size and nature of the spillage, this could cause water quality or sediment quality impacts along multiple reaches and it is therefore a potential impact of moderate magnitude and **Moderate** significance.
Chapter 8 Soils, Groundwater and Surface Water

The impacts associated with land clearance and earthworks are of moderate magnitude and **Moderate** significance prior to mitigation.

If the trenched pipeline is removed, then the impact on the watercourse will be of moderate magnitude and **Moderate** significance.

### 8.6.4.3 Mitigation and Monitoring

Potential impacts to soil, groundwater and surface water have been identified. The significance of these impacts has been assessed based on the sensitivity of each receptor and the expected magnitude of the potential impacts. The results of this assessment are presented in Table 8.25, Table 8.26 and Table 8.27.

As the potential impacts on soil and water during the Decommissioning Phase will be similar to those during the Construction Phase, the mitigation measures outlined in Section 8.6.2.2 will be relevant.

A detailed scope for appropriate monitoring will be developed at the time of decommissioning, taking into account prevailing environmental conditions, good international practice and available technology.

### 8.6.4.4 Residual Impacts: Decommissioning Phase

Table 8.25, Table 8.26 and Table 8.27 present a summary of the potential residual impacts to terrestrial soil, groundwater and surface water arising during the Decommissioning Phase following application of the identified mitigation measures.

**Soils**

The impacts assessed and the mitigation measures put in place reduce the residual impacts on soils to **Low** significance.

**Groundwater**

The impacts assessed and the mitigation measures put in place reduce the residual impacts on groundwater to **Not Significant** to **Low** significance.

**Surface Water**

The impacts assessed and the mitigation measures put in place reduce the residual impacts on surface water to **Low** significance.

*Complete.*
8.6.5 **Unplanned Events**
The potential impacts associated with unplanned events are discussed in **Chapter 19 Unplanned Events**.

Procedures to minimise the risk and impact of accidental spills will be developed within the Spill Prevention and Response Plan (Chapter 22 Environmental and Social Management). Spill kits shall be kept in accessible locations at all times during the Construction and Pre-Commissioning, Operation and Decommissioning Phases, and employees will be trained in their use and disposal. Considering the small size of any potential spillages and mitigation employed the impacts on soils, groundwater and surface water are expected to be **Low**.

8.6.6 **Cumulative Impacts Assessment**
All cumulative impacts identified are summarised in **Chapter 20 Cumulative Impact Assessment**.

8.7 **Conclusions**

8.7.1 **Soils – Construction and Pre-Commissioning Phase**
The soil receptors in the Study Area include agricultural soils, fluvisols, phaeozem soils and unstable geomorphic features. Construction workers are also a high sensitivity receptor for soils. The impacts pre-mitigation are **Low** to **High** significance. The Project Area impacts are primarily associated with potential contamination of the soils through use and storage of materials, increased susceptibility to erosion, changes in soil properties and unstable ground. Through mitigation the residual significance of the impacts are reduced to **Low**.

8.7.2 **Soils – Operational Phase**
The Project Area impacts pre-mitigation are **Moderate** significance. The impacts are primarily associated with potential for leaks and spills, vegetation management along the permanent RoW, and interaction of Project infrastructure with natural geomorphological processes. Through mitigation the residual significance of the impacts are reduced to **Not Significant** to **Low**.

8.7.3 **Groundwater – Construction and Pre-Commissioning Phase**
The groundwater receptors in the Study Area include superficial and carbonate aquifers and existing abstractions. The impacts pre-mitigation are **Not Significant** to **Moderate** significance. The impacts in the Study Area are primarily associated with potential contamination of the groundwater through use and storage of materials, groundwater control, the mobilisation of existing contamination and hydro-testing. Through mitigation the residual significance of the impacts are reduced to **Not Significant** to **Low**.
8.7.4  **Groundwater – Operational Phase**

The Study Area impacts pre-mitigation are Moderate to Low significance. The impacts are primarily associated with potential contamination and the potential influence of the pipeline structure on the groundwater flow regime. Through mitigation the residual significance of the impacts are reduced to Not Significant to Low.

8.7.5  **Surface Water – Construction and Pre-Commissioning Phase**

The Study Area surface water receptors include the Shingar River and the tributary of the Sukko River in the Graphova Gap and existing surface water abstractions. The Study Area impacts pre-mitigation are of Moderate significance. The impacts are primarily associated with the contamination of the surface water through use and storage of materials, construction of access roads, surface water run-off across disturbed soils and river crossing by the Pipeline. Through mitigation the residual significance of the impacts are reduced to Not Significant to Low.

8.7.6  **Surface Water – Operational Phase**

The Study Area impacts significance pre-mitigation are Low to Moderate. The impacts are primarily associated with impact on the surface watercourses through potential contamination, surface water run-off at landfall facilities and access road, and river crossings by the Pipeline and access road. Through mitigation the residual significance of the impacts are reduced to Not Significant to Low.

8.7.7  **Decommissioning Phases**

If the activities involve the removal of the trenched pipeline and access road then the impacts and pre-mitigation impact significances are likely to be similar to those reported during the Construction Phase. The exception being the impacts associated with microtunnelling and hydro-testing.

Through mitigation the residual significance of impacts on soil, groundwater and surface water can be reduced to Not Significant to Low. If the Pipeline is left in place then the impacts will be greatly reduced compared with the impacts if the Pipeline is removed. If the landfall facilities are removed then the impacts during the decommissioning works will be greater than if the facilities are left in place, but the long-term impacts on the water environment will be reduced if the facilities are removed.

9 Air Quality

9.1 Introduction

This chapter describes the atmospheric emissions associated with the Project and assesses their potential to affect existing and future air quality conditions.

Air quality is an important consideration in the ESIA process given its ability to affect human health and the integrity of the environment. High concentrations of pollutants can give rise to the following issues:

- **Adverse Human Health Effects.** Given the potential for air pollution to cause respiratory and cardiovascular illness among the more sensitive members of the population, air quality standards have been set both nationally and internationally. These standards form the basis against which Project emissions have been assessed;

- **Deterioration of Habitat Sites and Surrounding Land.** Nitrogen and sulphur deposition can alter the acidity of the soil, which in turn may inhibit the growth of particular types of flora. This is particularly important for projects in close proximity to critical habitats1 or to nationally or internationally protected areas2; and

- **Nuisance and Annoyance amongst Neighbouring Communities.** High dust emissions can lead to an increase in baseline deposition rates on property surfaces and agricultural crops, as well as, potentially affecting flora through the inhibition of plant growth.

In addition, it is widely acknowledged, scientifically, that the emission of greenhouse gases such as carbon dioxide (CO₂) and methane (CH₄) cause global warming, which in turn may affect weather and climate. Therefore, it is considered important to minimise greenhouse gas (GHG) emissions from the Project as far as is practicable3.

The aim of this air quality assessment is to determine the impacts to ambient air quality and the likelihood of any of the aforementioned issues occurring. Predictive modelling tools are used to quantify the air quality to the extent possible, and determine any predicted exceedences of Project standards. Where necessary, mitigation measures are specified to ensure applicable air quality standards are met.

---

1 As defined in International Finance Corporation Performance Standard 6.
2 Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology describe the existence of critical habitat in the Project Area of Influence, and also describe the Utrish State Nature Reserve that is located approximately 3 km south of the nearest Project Activities.
3 South Stream Transport has no influence over the energy strategies of European countries or their GHG emissions; however, it is able to manage its own GHG emissions resulting from the construction and operation of the Pipeline. The discussion about GHG emissions in this chapter is therefore limited to the Project's GHG emissions.
The key activities and emission sources during Construction and Pre-Commissioning Phases are considered to be:

- **Area and point sources** – nitrogen purging, dust generation and emissions from equipment (including diesel generators) used on the Project during site preparation, earth moving, pipe laying (both onshore and offshore) and other construction activities;
- **Mobile sources** – onshore and offshore emissions associated with deliveries, material movement and worker traffic during construction; and
- **Fugitive sources** – releases of fugitive dust from excavation activities and the movement of vehicles across unpaved roads.

An overview of the traffic associated with the Project is presented in Appendix 9.1 Traffic and Transport Study.

During the Operational Phase, activities will be limited to the operation of landfall facilities, periodic use of equipment to clean and inspect the pipelines, using pipeline inspection gauges (PIGs), and the intermittent use of maintenance and repair vehicles and vessels. Pigging will result in the release of a small volume of volatile organic compounds (VOCs) on an occasional basis (approximately once every five years).

This chapter provides a description of the air quality limits, the assessment methodology used, baseline conditions within the Study Area, the mitigation measures required to prevent, reduce or offset any significant adverse impacts, and the anticipated residual impacts after these measures have been employed. The likely potential for cumulative impacts when considering the Project along with other planned developments in the surrounding area is discussed in Chapter 20 Cumulative Impact Assessment and the cumulative impacts associated with the Russkaya Compressor Station are discussed in Appendix 20.1 Environmental Impacts of Associated Facilities: Russkaya Compressor Station.

### 9.2 Scoping

This chapter focuses on the key aspects and activities which may result in impacts on air quality. Non-key aspects and activities have been scoped out, with further justification provided below.

Air quality effects can be wide ranging and to varying levels of severity. Therefore, some air quality aspects have been scoped out of this assessment as they are considered to be below any measurable or noticeable level of change, although they are briefly mentioned where appropriate as confirmation that they have been considered and scoped out.

The assessment has focused on the key pollutants of concern in the Study Area (Section 9.3) and the main emissions from the Project Activities. The main source of airborne pollutants from the Project is expected to occur from the combustion of diesel and marine fuels and associated engine exhaust emissions. In addition, construction and earth moving activities associated with the generation of dust are also anticipated. Other airborne pollutants are considered to be emitted in such small or immeasurable quantities that they have been scoped out of this assessment. The main pollutants of concern are discussed below in more detail.
• **Nitrogen dioxide (N₂O):** Oxides of nitrogen (NOₓ) are formed as a by-product of the combustion of fossil fuels (such as natural gas) by the oxidation of nitrogen contained in the air and in the fuel. NOₓ is primarily emitted as nitrogen oxide (NO), but also includes a small proportion emitted as nitrogen dioxide (NO₂); once emitted the former can be oxidised in the atmosphere to produce further NO₂. It is NO₂ that is associated with adverse health impacts and at high concentrations it can affect lung function and airway responsiveness, and exacerbates asthma and mortality. The rate of conversion of NOₓ to NO₂ in the atmosphere is discussed later in this report;

• **Sulphur dioxide (SO₂):** SO₂ is a colourless gas that is readily soluble in water. It is formed through the combustion of sulphur containing fossil fuels and is a major air pollutant in many parts of the world. Excessive exposure to SO₂ (above the limit values) may cause discomfort in the eyes, lungs and throat and the United States Environmental Protection Agency (USEPA) have linked exposure to mortality;

• **Carbon monoxide (CO):** CO is formed by the incomplete combustion of carbon containing fuels such as natural gas. Exposure to high concentrations causes carboxyhaemoglobin 4, which substantially reduces the capacity of the blood to carry oxygen;

• **Volatile Organic Compounds (VOCs):** VOCs are a group of organic compounds that evaporate relatively easily into the air. They form a by-product of combustion and are also naturally present in fossil fuels. Benzene is a widely regulated VOC, which is a recognised carcinogen in humans. Non-methane VOCs (NMVOCs) exclude methane, methane has been considered separately in this assessment due to its global warming potential;

• **Particulate Matter (PM):** Air quality limits exist for total suspended particulate matter, which is all suspended particulate matter suspended in the air, and the finer PM₁₀ and PM₂.₅ size fractions, which can penetrate deeper into the lungs. PM₁₀ and PM₂.₅ are defined as particulate matter with an equivalent aerodynamic diameter of less than 10 and 2.5 microns (µm), respectively. Exposure to increased concentrations of PM₁₀ and PM₂.₅ is consistently associated with respiratory and cardiovascular illness and mortality;

• **Dust:** Dust is generally regarded as particulate matter less than 75 µm and can include suspended and deposited particulate matter. The effects to humans of construction activities from dust are two-fold; as a potential nuisance, and as having the potential to cause human health effects. Complaints against construction works are often associated with the former, relating to deposition of dust on windows, cars, and the outside of buildings, with the latter being from a finer fraction of the dust. In extremely large quantities, dust can also smother vegetation reducing photosynthesis and growth rates. Large dust particulates (greater than 30 µm), which makeup the greatest proportion of dust emitted from construction works, will largely deposit close to any such works; and

• **Greenhouse Gases (GHG):** Emissions of GHG have also been considered within this assessment due to their potential importance with regards to global warming, in particular

---

4 A stable complex of carbon monoxide and haemoglobin that forms in red blood cells upon contact with carbon monoxide (CO).
emissions of CO₂ and methane. However, these gases do not have air quality limit values against which to assess Project emissions.

An estimated emissions inventory is provided in this assessment in Section 9.6.6 in tonnes per year of pollutant (additional details on GHG emissions and methodology are provided in Appendix 9.5: Atmospheric Emissions from South Stream Russia Construction and Pre-Commissioning Phase). This is provided for emissions reporting purposes and should not be confused with assessment of impact magnitude and significance.

The air quality standards relevant to the Project are set out in Section 9.6.1.1. The Project Standards are based on Russian Federation national limits (Ref. 9.1) and standards referred to in the International Finance Corporation (IFC) Environmental, Health and Safety General Guidelines (Ref. 9.2), which are in turn, based on the World Health Organisation (WHO) Air Quality Guidelines (Ref. 9.3).

### 9.3 Spatial and Temporal Boundaries

For the Construction and Pre-Commissioning Phase and the Operational Phase of the Project, the Project Area (as defined in Chapter 1 Introduction) is sub-divided into the following sections where certain activities which give rise to airborne pollutants could occur:

- **Offshore Section** – All marine based activities located at water depths of greater than 30 m. It extends from the border of the nearshore section to the border of the Russian and Turkish EEZs in the Black Sea;

- **Nearshore Section** – Marine based activities which commence at the exit point of the microtunnels, located approximately 400 m from the coast at a water depth of approximately 23 m and extends approximately 425 m out to a water depth of 30 m; and

- **Landfall Section** – any activity that occurs on the land including the Pipeline permanent Right-of-Way (RoW), landfall facilities and access roads.

Although the ports have not been confirmed, for the purposes of this ESIA Report, activities within the existing port at Novorossiysk have been considered and assessed on the basis that this is one of the ports most likely to be used.

In general, airborne pollutants once emitted can travel for long distances and cross national and international boundaries, although the atmospheric emissions generated by the Project Activities are expected to disperse relatively quickly and to have a limited geographical extent. Considering this and for the purposes of this assessment the air quality Study Area has been further defined as:

- **Offshore Study Area** – An area of 2 km around the Pipeline route (Offshore) in water depths greater than 30 m; and

- **Nearshore and Landfall Study Areas** – Preliminary modelling demonstrated that the maximum impacts of the Project would occur within a 2 km buffer, and this distance is considered adequate for the Study Area. A more detailed 200 m buffer area either side of the Pipeline RoW (landfall) and access roads was also considered part of the Study Area.
There are several residential areas and sensitive habitats within the Study Areas. These include a Kindergarten and a large school within the nearest town of Varvarovka, as well as other nursery and primary schools within other local communities. There are high schools in Gai Kodzor and Supsekh. There are also local outpatient facilities within the local towns, including Varvarovka; the nearest hospital is in Anapa. The sensitive habitats are described in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology.

Certain offshore receptors such as workers on the Project vessels would not be subject to air quality limit values discussed within this chapter (instead they would be subject to occupational exposure limit values which are not covered within this air quality assessment). An exclusion zone of 2 km will be enforced around the RoW (offshore) and therefore offshore human receptors and, as such, the Offshore Study Area are not considered in this assessment.

Full details of activities associated within the Study Area are presented within the impact section for each corresponding Project phase.

Port facilities and haulage routes are discussed within the assessment despite being outside of this defined Study Area. Unless specifically mentioned in the assessment, all other topic specific Study Areas (e.g. terrestrial ecology) are considered outside the scope of the air quality assessment. The Study Area is illustrated in Figure 9.1.

Air quality surveys were conducted in 2012 and 2014 (see Section 9.4.4 for details). The locations of the surveys were selected to inform the underlining baseline conditions of the area. The air quality Survey Area is thus the spatial extent of these surveys and is presented in Figure 9.2.

Secondary data was also collected from a variety of sources (see Section 9.4.2) to inform the baseline. Data collected from secondary sources forms the baseline of the Wider Study Area which encompasses the Study Areas and the Survey Area, mentioned above.

### 9.4 Baseline Data Collection

#### 9.4.1 Methodology and Data

This section discusses details of air quality surveys carried out across the Survey Area as well as data sourced from secondary parties. This is used to inform the baseline conditions.

#### 9.4.2 Secondary Data

Secondary data has been provided by the "Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring" for 2012 (Ref. 9.4) to help establish the baseline conditions at the Wider Study Area.

Background pollutant concentrations have been provided by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring for the three towns of Anapa, Varvarovka and Gostagaevskaya. Country emissions data is available from the European Monitoring and Evaluation Programme (EMEP) Centre on Emission Inventories and Projections (CEIP) for pollutants, and the United Nations Climate Change Secretariat (Ref. 9.5) for GHGs.
9.4.3 Data Gaps

To determine baseline concentrations, it is important that a range of sources are used to provide a good representation of air quality in the Wider Study Area. The Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring data is based on measurements taken in central Anapa, and as such is likely to be representative of areas with higher baseline pollutant concentrations than those experienced in more rural environments within the Wider Study Area. Therefore, it was deemed necessary to obtain primary data to supplement the available secondary data for the Study Area.

9.4.4 Primary Data and Baseline Surveys

A two-month survey of air quality was undertaken within the Survey Area between August and October 2012. The purpose of this survey was to confirm that the available secondary data is representative of the Study Area or, if not, to provide new data on which to base the impact assessment. A further diffusion tube monitoring survey commenced in February 2014, focussed on the area affected by early works activities. The first month of results from the monitoring are also included in this chapter, and provide some indication of the seasonal variation in background pollutant concentrations during the winter months. The survey is ongoing and further results will be incorporated into the project dataset and, if appropriate, used as the Environmental and Social Management Plans (ESMPs) evolve.

The air quality survey was undertaken using a network of diffusion tubes (passive sampling devices containing a steel mesh impregnated with a sorbent material or sorbent chamber) onto which specific gases are absorbed or adsorbed. Diffusion tubes have limitations to the data quality which are discussed in Section 9.4.5.

Monitoring was undertaken at nine sampling locations for two successive one-month periods between 15 August and 19 October 2012, as shown in Figure 9.2 and described in Table 9.1. This is considered a snap shot of conditions and results are likely to be less representative than annual datasets. The monitoring locations were selected to include a variety of sites along the construction corridor, some nearby residential dwellings and educational facilities that are likely to be more affected by the Project, and the suburbs of other less affected settlements.

The survey was undertaken for selected pollutants detailed in the Section 9.2, which are of known human health risk commonly associated with fuel combustion; namely SO\textsubscript{2}, NO\textsubscript{2}, and benzene. For PM\textsubscript{10} and total particulate matter (airborne particulate matter of all size fractions), which cannot be sampled using passive methods such as diffusion tubes, it was considered sufficient to rely on secondary data rather than install automatic monitoring stations.

The 2014 monitoring survey commenced on 18 February and the monitoring locations are shown on Figure 9.2 and described in Table 9.12. The survey was undertaken for a number of pollutants commonly associated with road traffic emissions and fuel combustion; namely SO\textsubscript{2} and NO\textsubscript{x}. Due to the low results obtained from the 2012 survey, the measurements for benzene were not repeated.

The locations of the diffusion tube monitoring are presented in Table 9.2.

9.4.5 Data Assumptions and Limitations

The secondary data reported by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring are derived from short term monitoring undertaken in central Anapa, which is outside of the Study Area, but within the Wider Study Area, and not wholly representative of long term conditions at the worst affected receptors adjacent to the RoW.

The diffusion tube monitoring locations provide a good representation of the annual average concentrations for each pollutant within the Study Area. The survey period will not have captured the seasonal variation in concentrations related to meteorological conditions. They are, however, easily deployed and are useful in providing indicative concentrations at a variety of locations within the Project Area. The samples were analysed using a UK Accreditation Service (UKAS) certified laboratory based in the UK.

It is not considered that the above is a substantial limitation given the findings of the assessment. This is discussed in more detail in Section 9.6.

9.4.6 Model verification and validation

The assessment is not able to verify modelled predictions against measured baseline concentrations due to the lack of emission sources in the existing environment; this can only be achieved once emission sources are present. Instead the assessment relies upon validation. The model producer CERC has produced a number of validation papers for the dispersion model used in this assessment, ADMS, which shows the approximate level of accuracy. An overview of the model and these validation papers is presented in Appendix 9.2: Overview of ADMS and Model Validation.

9.5 Baseline Characteristics

9.5.1 Meteorological and Climatic Conditions

The Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring has provided a climatic summary for the period from 1977 to 2009 (Ref. 9.4), based on the nearest meteorological station to the Project, which is located in Anapa, 5 km north of the proposed Pipeline route (World Meteorological Organisation Station ID 37001).

Table 9.3 provides a summary of the average monthly air temperature onshore. The annual average temperature is 12.1 Celsius (°C), with the coldest months shown as December to March and the warmest months June to September. The maximum average monthly temperature occurs in July and is 23.1°C. The minimum average monthly temperature occurs in January, and is 1.8°C.

</table>

Although not shown in Table 9.3, the estimated average maximum daily air temperature occurs in July and is 29.0°C. The estimated average minimum daily air temperature occurs in January and is -2.2°C.

Table 9.4 provides a summary of the wind data based on the climatic record. The predominant wind direction is north-easterly (i.e. blowing from the northeast) occurring for 25% of the year, followed by southerly winds for 21% of the year, easterly winds for 17% of the year and northerly winds for 11% of the year. The wind speeds are generally highest during southerlies, with an average speed of 6.7 metres per second (m/s) and a maximum recorded wind speed of 34 m/s during the 32 year record. The maximum recorded wind speed during this period was 40 m/s, which was recorded during a south-westerly wind.

Table 9.5 presents the average monthly and annual precipitation amounts at Anapa meteorological station. The annual average rainfall is shown to be 539 millimetres (mm), with the slightly higher quantities occurring during the winter months of November to February. The daily maximum rainfall event during the climate record is 85.9 mm. The deepest snowfall on record is 33 cm, though snowfall is generally sparse in comparison with the rest of the region and Russian Federation.

The climatic data is not considered further in this assessment given that it is not expected to be affected by the Project.

Local meteorological conditions can, however, affect the plume dispersion of emissions downwind of the site, with plumes being largely transported in the direction of the wind. Atmospheric conditions influence both plume spread and the rapidity it reaches ground level.

The atmospheric dispersion model used for the assessment (discussed in Section 9.6.2) requires measurements of wind speed and direction, ambient temperature, humidity, cloud cover or solar radiation and estimates of the urban and rural mixing heights. Ground level concentrations are computed for each hour of meteorological data for specified averaging periods and receptor points. It is typically recommended to use meteorological data from a monitoring station as close to the assessed site as possible, since this is likely to be exposed to similar weather conditions.

Hourly sequential meteorological data from Anapa meteorological station, for the years 2008 to 2012 inclusive, has been utilised for the assessment. The use of data from a five year period is likely to have captured much of the variation in meteorological conditions that would be experienced within the Landfall and Nearshore Study Area. This is not necessarily representative of meteorological conditions offshore, but impacts to offshore receptors are not considered within this assessment.

Figure 9.3 shows the typical wind speed and direction experienced at Anapa Meteorological Station for each of the five years within the dataset, with the predominant wind direction being north-easterly. It is therefore reasonable based on this data to expect that air emissions from the Project Area will generally be dispersed to the southwest (to sea) over the longer term.
Figure 9.3 Wind Roses, Anapa Meteorological Station (2008 to 2012)
9.5.2 Baseline Air Quality

9.5.2.1 Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring Data

In order to assess the Project’s potential to impact local air quality, it is necessary to first determine the baseline ambient air quality.

Background air pollutant concentrations in the Wider Study Area have been provided by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring for the three towns of Anapa, Varvarovka and Gostagaevskaya. These are illustrated in Figure 9.2. It is understood that the values are derived from monthly spot sampling at a site in central Anapa, and extrapolated to provide values for other areas. As the monitoring is short-term, it is considered that these values are representative of short term concentrations (less than a 24 hour averaging period) rather than long term annual average concentrations.

The concentrations for 2012 (the most recent data) are summarised in Table 9.7. Concentrations are presented in µg/m³ unless otherwise stated. Any exceedences of the Project Standards (Table 9.7) are highlighted in bold font.

</tbody>
</table>

* APC – Equivalent to Annual Mean. MPC – Maximum 20 minute mean (Maximum Permissible Concentrations)

The reported concentrations of SO₂, CO and NO are below the long term and short term Russian Limits and adopted Project Standards. If the reported NO₂ concentrations are assumed
to be representative of the annual mean then the Russian Limit and Project Standard would be exceeded at all three locations, but the short term criteria are not exceeded. Concentrations of total particulate matter reported for Anapa and Gostagaevskaya are in excess of the long term Russian limit value but below the maximum peak MPC value.

The monitoring station in Anapa is located in an urban area, whereas the land in the vicinity of the Project Area is more rural in character. The area around the monitoring station is likely to experience higher concentrations of pollutants than those experienced in close proximity to the Project, particularly in the case of substances associated with emissions from road traffic and other sources such as NO₂. Total particulate matter concentrations could also be linked to road traffic levels, both due to exhaust emissions and through the re-suspension of road dust. In rural areas, overall concentrations of airborne total particulate matter are likely to be much lower, despite farming activities, e.g. the movement of machinery on un-surfaced ground representing occasional sources of emissions.

9.5.2.2 Diffusion Tube Monitoring Results

Table 9.8 presents the findings of the diffusion tube monitoring. Concentrations are presented in micrograms per cubic metre (µg/m³).

*Continued...*
The following conclusions can be drawn from the diffusion tube monitoring undertaken within the Survey Area:

1. Measured concentrations are below the national and IFC guideline annual limits for the parameters monitored;
2. Monthly average SO₂ concentrations are between 14% and 30% of the Russian Federation annual APC, and broadly similar to the concentrations measured by the Krasnodar Regional Centre;
3. NO₂ concentrations are between 14% and 31% of the Russian Federation annual APC and mean annual IFC limit, and considerably less than the concentration values derived from monitoring within central Anapa (in Table 9.8); and
4. Benzene concentrations are below the Russian Federation annual APC.

The diffusion tube data are limited in temporal extent (it presents only two months of data and shows variability between months for some pollutants and/or monitoring locations); however, it still does provide an indication of long term average concentrations within the Survey Area located away from major urban settlements and associated emissions such as road traffic and industry.

Table 9.9 presents the findings of the first month of diffusion tube monitoring from the 2014 survey. Concentrations are presented in μg/m³. The monitoring equipment placed at location 1 was missing at the end of the one month period, so there is currently no data available for this site.

The following conclusions can be drawn from the first month of results from the 2014 diffusion tube monitoring undertaken within the Survey Area:

1. Measured concentrations remain below the national and IFC guideline annual limits for the parameters monitored in the winter months, when concentrations are likely to be higher than in summer;

2. SO₂ concentrations are lower than those measured in the 2012 survey, despite the likely increase in domestic fuel use during the winter period;

3. NO₂ concentrations measured at locations 2, 3 and 5 are slightly higher than other measurements from Varvarovka in the 2012 survey. This indicates that background NO₂ concentrations may increase by a small amount in the winter months. The concentrations remain below 35% of the annual mean project standard. The measurement at location 4 is however consistent with background measurements from 2012;

4. NO₂ concentrations at locations 6 and 7 are influenced by nearby sources of road traffic emissions. Measured concentrations remain well below the project standards.

5. NO₂ concentrations remain considerably less than the concentration values derived from monitoring within central Anapa (in Table 9.9);

The diffusion tube data are currently limited in temporal extent (although only one month of data it is considered to be representative of the winter when higher concentrations are likely to be observed). The early results of the 2014 survey confirm that the 2012 monitoring does provide a reasonable indication of concentrations within the Survey Area located away from major urban settlements and associated emissions such as road traffic and industry.

### 9.5.3 Baseline Summary

The baseline section has considered the existing climatic and air quality conditions.

The climate data has been sourced from Anapa meteorological station and shows that the climate is typical of a coastal location within the Krasnodar region.

Air quality baseline conditions have been derived using a combination of data provided by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring for the three towns of Anapa, Varvarovka and Gostagaevskaya, and a two month diffusion tube survey at nine sampling locations within the Project RoW and immediate surrounds.

Concentrations reported by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring exceed the air quality limits for annual average NO₂ and particulate matter concentrations. These values, however, are derived from short term monitoring undertaken in central Anapa, which is outside of the Study Area and not necessarily representative of conditions at the worst affected receptors adjacent to the RoW.

The diffusion tube monitoring data indicates that the annual mean project standards for the parameters monitored are not exceeded, with NO₂ concentrations between 14% and 31% of the annual mean project standard. This is considerably less than the concentration reported by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring, and concentrations of this magnitude indicate that the short-term standards are also unlikely to be
regularly exceeded in the baseline, given the lack of existing major sources of emissions in the vicinity of the construction site. The large difference between the NO₂ diffusion tube data and Krasnodar Regional Centre data also indicates that particulate matter concentrations in the Study Area would also be considerably less than those found in central urban locations.

The diffusion tube data are limited in temporal extent, but the monitoring data taken from both summer and winter months can still be considered to be indicative of long term concentrations within the construction corridor and at the nearest rural dwellings.

# 9.6 Impact Assessment

## 9.6.1 Impact Assessment Methodology

This section discusses the approach to determining the potential impacts associated with the Project on the baseline conditions described in Section 9.5.

The potential impacts upon the air quality are derived through the activities of the Project. These are described in detail in Chapter 5 Project Description of this ESIA Report and Table 9.10 outlines the key activities that are likely to give rise to air emissions and where this is likely to occur.

Table 9.11 presents the applicable Project Standards and relevant ambient air quality standards for the Project, based on the Russian Federation national limits (Ref. 9.1), Bulgarian National Limits and the IFC Environmental, Health and Safety General Guidelines (Ref. 9.2), which are in turn based on the WHO Air Quality Guidelines (Ref. 9.3). Note that Project Standards have been adopted across both Russia and Bulgaria. This assessment focuses on the assessment of Russian National limit values for the purposes of assessing air quality impacts and is supplemented with IFC standards where applicable.

Concentrations are presented in micrograms pollutant per cubic metre of air (µg/m³), except CO which is reported in milligrams CO per cubic metre of air (mg/m³)\(^5\).

---

\(^5\) There is a factor of 1000 difference between µg/m³ and mg/m³. For example, the MPC for NO₂ is 200 µg/m³, which is the equivalent of 0.2 mg/m³.

# Interim Target 1. The guideline limit is 100 µg/m³

Russian Federation limits (Ref. 9.1) require pollutants to be no more than a factor of 0.8 (80%) of the Maximum Permissible Concentration (MPC) in Sanitary Protection Zones (SPZs), which is a buffer zone between the Project and nearby residential areas. It is established for industrial facilities that emit pollutants into the atmosphere or have other environmental impacts. The SPZ is illustrated in Figure 9.4, along with the nearby sensitive receptors.

National limits are also provided for hydrogen disulphide, benzo(a)pyrene, and formaldehyde in the Russian Federation. These pollutants are not expected to be emitted in large quantities by activities associated with the Project and there are no known large emission sources of these substances in the vicinity of the Pipeline route. For these reasons, these pollutants have not been assessed further.

There are no known regulatory or guidance limits available in the Russian Federation regulations or IFC guidelines for assessing the effect of dust deposition for either habitats or people. Guidance levels vary country to country. For example, a guideline level of 200 milligrams per square metre per day (mg/m²/day) is typically used within the UK to indicate the potential for dust nuisance by the UK Environment Agency, while in South Africa 600 mg/m²/day is the action level for residential areas, below which the risk of nuisance is considered low.

There are no known limits for assessing impacts on atmospheric concentrations of pollutants at protected habitats in the IFC/World Bank guidance or Russian Federation regulations. Utrish State Nature Reserve is the closest designated site to the Project, located approximately 3.2 km southeast of the microtunnel entry points (the closest point of the Pipeline). Chapter 11 Terrestrial Ecology has also identified critical vegetation in the Study Area that has not been designated as a state reserve.

In the absence of criteria for the protection of flora and fauna, and to allow an assessment of potential impacts on air emissions on protected and non-protected vegetation, the critical levels...
set out in European Union Directive 2008/EC/50 for the protection of ecosystems have been applied to this assessment for locations outside of urban settlements. These limits are presented in Table 9.12 in µg/m³.

**9.6.1.2 Impact Assessment Criteria**

**Chapter 3 Impact Assessment Methodology** presents full details of the assessment of impact significance and this chapter outlines how these assessment criteria apply specially for air quality. While a number of national and international air quality standards may apply to the Project, there is relatively little guidance on the assessment of air quality impact significance. Some guidance on this issue is provided by the IFC, which recommends that any new project should contribute at most 25% of any applicable ambient air quality limit to allow for future developments (Ref. 9.2). In this case, however, much of the potential impacts on air quality would occur during construction and would hence not degrade the airshed over the long-term.

The criteria used in describing receptor sensitivity and impact magnitude in this ESIA have taken into account IFC guidance (Ref. 9.2) as well as technical guidance from the international community, as detailed in **Chapter 3 Impact Assessment Methodology**. The Russian Federation provides ambient limits (see Table 9.11) but there is no known guidance on attributing significance to modelled increases in pollutant concentrations. Subsequently, the criteria used in describing receptor sensitivity and magnitude of impacts for this ESIA Report have taken technical guidance from the international community into account, in particular the guidelines provided by the air quality regulators and professional bodies from the UK (Ref. 9.6 and Ref. 9.7).

The significance of a predicted air quality impact in this ESIA Report has been determined taking into account air quality limits (receptor sensitivity), and the predicted magnitude of impact associated with the Project (magnitude of change). These two considerations are discussed in further detail below.

**9.6.1.3 Receptor Sensitivity**

In general, air quality limits for the protection of human health (shown in Table 9.11) are set at a level that research indicates is “safe” for the general public. In theory, air quality concentrations sustained above the prescribed limits have the potential to lead to adverse health effects. Similarly, air quality levels for the protection of sensitive ecosystems and habitats
(i.e. those habitats which are likely to demonstrate a significant ecological response to the air quality parameter under consideration) are set at a level which should not lead to a deterioration of such ecosystems. A receptor is therefore considered particularly sensitive where concentrations are approaching or already exceed the critical levels, as any increase is likely to have a perceptible effect on the habitat under consideration.

It is also acknowledged that the characteristics of receptors may affect their sensitivity to changes in air quality concentrations. For example, in general, the elderly and very young are more likely to be adversely affected by changes in air quality than middle aged adults. Therefore, some locations (e.g. hospitals, nursing homes, schools) are considered to represent locations of higher sensitivity. In addition some habitats may be highly sensitive to changes of a particular pollutant but be more resilient to increased levels of others.

Table 9.13 presents a description of receptor sensitivity, using the categories High, Moderate, Low, and Negligible. These descriptors have been developed specifically for the Project, although they are in part based on the aforementioned guidance methodology. Receptor sensitivity for ecosystems/habitats uses definitions provided with Chapter 11 Terrestrial Ecology, though re-assigned for specific sensitivity to air quality.

The human health criteria do not apply to Project workers who would be covered by health and safety standards, places of work which are not relevant to the ambient air quality limits, or locations where people are not expected to be present for sufficient time for these limits to be judged to be applicable.

<tr>
<td></td>
<td>Within an ecosystem/habitat type which is either appreciably degraded/disturbed by human activity, have low diversity of common and widespread species or have high proportions of invasive/non-native species and would not likely to be affected by air quality levels.</td>
</tr>
</tbody>
</table>

* As defined in EU Directive 2008/50/EC (Ref. 9.8)

It is possible for a receptor to have a different level of sensitivity to different pollutants and averaging periods. For example, concentrations may exceed the short-term limit for nitrogen dioxide, yet easily comply with the limits set for other pollutants, meaning that a receptor in this location would have a high sensitivity to NO\(_2\) but a low or negligible sensitivity with regards to other pollutants. Where relevant, this has been discussed in the assessment.

9.6.1.4 **Impact Magnitude**

Table 9.14 presents a description of the magnitude of change, using the classifications High, Moderate, Low and Negligible.
The impact magnitude criteria are based on aforementioned guidance, using a change that is more than 25% of a limit (the IFC industry benchmark) as the definition for a high impact magnitude event. The banding for impact magnitude is based on professional judgement, taking into account the aforementioned guidance provided by the air quality regulators and professional bodies referred to in Section 0.

The frequency and reversibility of impacts are not assigned in the impact magnitude but are instead addressed in context, where appropriate, throughout the assessment. The air quality limits are based on specific averaging periods which by default define frequency.

**Table 9.14 Magnitude Criteria**

</tbody>
</table>

9.6.1.5 Sensitive Receptors

As stated in Section 9.2, the atmospheric emissions from the Project are anticipated to disperse very quickly after the point of release and as such only have the potential to affect receptors within close proximity to the Project Activities. As such only the closest receptors have been
identified for inclusion within the modelling assessment. These receptors could also potentially be affected by the construction and operation of the Russkaya CS, and this is considered further in Appendix 20.1.

**Human Health Receptors**

Identified human health receptors within the Wider Study Area are described Table 9.17 and are illustrated in Figure 9.4. Figure 9.4 also shows the location of the SPZ at which concentrations should not exceed 0.8 (80%) of the MPCs.

</tr>
</tbody>
</table>
Locations where members of the public may be present for a short period of time, such as footpaths and countryside, are considered relevant to the assessment of short-term concentrations (e.g. limits where the averaging period is 24 hours or less) and have been assessed using a regular spaced grid of receptors to calculate the maximum short-term model (known as a Cartesian Grid of receptor points).

**Ecological Receptors**

In addition to residential receptors there are also several nationally and internationally protected habitat sites that may be considered sensitive to air emissions attributed to the Project. The closest designated habitat site is the Utrish state national reserve, which is located approximately 3.2 km southeast of the microtunnelling location (and also extends into the nearshore water), as shown in Figure 9.4. There is also habitat through which the landfall section will be constructed, as described in **Chapter 11 Terrestrial Ecology**, and other sensitive land uses such as vineyards in the area.

In contrast to land based receptors, the potential for air quality impacts upon offshore marine environments was considered to be outside the required scope of this air quality assessment. No limits exist for the assessment of air quality impacts on seawater or marine ecology. Consequently, offshore was not considered to have any potential receptors.

**9.6.1.6 Study Area Sensitivity**

This section identifies and evaluates the sensitivity of receptors within the Study Area. The Project is located within a relatively isolated, vegetated area, with very few human receptors.

Study Area sensitivity criteria presented in Table 9.18 combines the Study Area's baseline concentrations with the sensitivity criteria, presented in Table 9.13 based on pollutant and averaging period. It is possible for a receptor to have a different level of sensitivity to different pollutants and averaging periods. For example, concentrations may exceed the short-term limit for NO2 yet are easily aligned with the limits set for other pollutants, meaning that a receptor in this location could have a high sensitivity to NO2 but a low sensitivity to other pollutants.

As discussed earlier in this chapter, the Study Area does not consider offshore emissions sources and receptors. It is considered that air quality conditions offshore would be similar or lower than background air quality conditions on land, due to limited proximity of human activity and the free atmosphere over large water bodies. Offshore sensitivity is not considered further in this assessment.

Table 9.18 summarises the perceived sensitivity of the Study Area, based on the monitoring data presented in Table 9.8 and Table 9.9, and the descriptors presented in Table 9.13. The sensitivity of each of the discrete sensitive receptors listed in Table 9.18 for the pollutants assessed, can be found in Appendix 9.4: Dispersion Modelling Results Tables Commissioning Phase.

The receptor sensitivity is low for SO2, NO and NO2. Although rural concentrations are likely to be well below those reported in urban centres, a moderate sensitivity has been assumed for CO. A high sensitivity is assumed for total particulate matter, PM10 and PM2.5, at all locations in
the Study Area. Finally, it is assumed that receptors are of negligible sensitivity to benzene due to anticipated low baseline concentrations resulting from the absence of local emission sources.

The closest and potentially worst affected sensitive receptor is Receptor 5, which is also on the boundary of the SPZ. Table 9.19 summarises the baseline concentrations that have been assumed for this Receptor. These concentrations are also likely to be representative of background values elsewhere within the Study Area.

9.6.2 Modelling Undertaken

This section provides an overview of the modelling undertaken using atmospheric dispersion modelling software to establish impact magnitude from activities.

Where necessary, the atmospheric dispersion model ADMS 5 has been used to model or screen the predicted impact of atmospheric emissions associated with the Project. ADMS 5 is an internationally recognised dispersion model, which is regularly used in the UK, USA, Europe, Middle East, and Asia.

ADMS 5 is an advanced Gaussian plume dispersion model specifically designed to model a wide range of emission sources. The model uses hourly sequential meteorological data to enable a realistic assessment of dispersion from point sources to be conducted for weather conditions that are directly applicable to the site. See Appendix 9.2 for an overview of ADMS 5 and comparisons to other internationally recognised or well-known models.

Unlike some of the other pollutants mentioned in this assessment, emissions of NOₓ vary dependant on a wide number of combustion variables and are also subject to chemical reactions in the atmosphere. Due to this, it is necessary to state how NOₓ transformation has been considered in this assessment. In practice, typically 5% to 10% of NOₓ emitted from the
engine exhausts of site plant and vessels is expected to be in the form of NO$_2$ at the point of
discharge (i.e. stack exit), the remainder being NO. NO is a less harmful pollutant than NO$_2$ but
it is of interest as a precursor to NO$_2$. The conversion of NO to NO$_2$ takes place in the
atmosphere under the influence of several factors, primarily the availability of ozone (O$_3$).
However, the chemistry of this conversion is complex and subject to many influences, and
therefore, it is not possible to accurately predict the rate of conversion of NO to NO$_2$. As such, a
conservative conversion factor has been applied in order to calculate NO$_2$ concentrations at
ground level. For the purpose of this assessment, a 35% conversion factor for NO$_x$ to NO$_2$ has
been used for this study for short-term$^6$ averages of 24 hours or less (including the MPC), and
100% to calculate annual average NO$_2$. This assumption is considered conservative and is
expected to lead to a higher estimation of ground-level NO$_2$ concentration than would occur in
practice (Ref. 9.7 and Ref. 9.9).

The estimated exhaust emissions from the site plant and vessels have been calculated using the
European Environment Agency (EEA) Air Pollutant Emission Inventory Guidebook 2009
(Ref. 9.10).

### 9.6.2.1 Traffic Modelling

The UK Design Manual for Roads and Bridges (DMRB) screening tool (Ref. 9.6) has been used
to screen the impact of additional Project related road traffic movements on NO$_2$ and PM$_{10}$
concentrations adjacent to affected routes, in the absence of local guidance on the assessment
of road traffic emissions. Although the screening tool no longer contains the most recent
version of the UK vehicle emissions factor database, it can be considered to be representative of
emissions from older Euro I type vehicles, and as such, its use within this assessment can be
considered to be robust. The screening tool was originally developed to indicate whether more
complex and sophisticated modelling of air quality is required and a number of features of the
DMRB procedures are designed to overestimate road traffic emissions. Therefore, it can be
assumed with some confidence that any change in road traffic flows will not result in any air
quality problems if none are predicted using the DMRB methodology.

### 9.6.2.2 Vessel Modelling

Vessels are not static sources which makes it difficult to model their impact on a particular
terrestrial receptor. In order to consider the impact on annual mean pollutant concentrations at
receptors, vessels were therefore modelled as line sources. The maximum impact on short-term
concentrations, however, would be seen during times when vessels are at their closest point to
shore, so the modelling of short-term concentrations has been undertaken by representing the
vessel fleet as a series of point sources in this location, so that the impact on short-term
concentrations throughout the full range of meteorological conditions can be evaluated. Full
details on Vessels usage and the expected number of days of operation are outlined in
Chapter 5 Project Description.

---

$^6$ Short-term standards include the 10 minute, 20 minute (MPC), 1 hour, 8 hour and 24 hour averaging periods, which
are used to assess short-term exposure. Long-term standards include the annual average and APCs.
In order to consider the impact on mean annual concentrations onshore, the vessels’ emissions were modelled using a number of line sources to represent each section of water: a 470 m line source for nearshore vessels in depths of 23 to 30 m near to the micro tunnel entrance and 47 km for offshore vessels operating in depths of 30 to 600 m. The offshore vessels in depths over 600 m are more than 15 km from the shore and have not been modelled. Figure 9.6 illustrates the indicative locations of these line sources in the ADMS 5 model.

The line sources used in the assessment of the contribution to annual mean pollutant concentrations have been allocated a release height of 20 m and an emission temperature of 200°C, using emission rates presented in Table 9.20. The assessment of impacts on annual mean concentrations has taken into account the expected utilisation and time on task of the shipping types to be employed through the calculation of an emission rate factored over one calendar year, but the use of a complete year of meteorological data for a construction fleet moving at a speed of up to 3 km per day ensures a robust assessment of impacts.

The emission factors were derived using the known vessel types, Table 3-2 of the EMEP / EEA emission factors, Chapter 1.A.3.d of the 2009 EMEP / EEA Emission Factors, (Ref. 9.10), and the expected number of days of operation outlined in Chapter 5 Project Description. The output from the modelling of the shipping emission sources described in Table 9.20 has been combined with the annual mean output from the construction plant model described in Section 9.6.2.3, in order to enable an overall assessment of the impact of activities on long term pollutant concentrations to be made.

* Calculated based on 1.5% sulphur content in the fuel which is typical for Marine Diesel Oil (MDO) purchased in Russia

With respect to emissions from shipping which could cause short term impacts on sensitive receptors near to the shore line, it is considered that that the shallow water pipe lay operations to be undertaken in close proximity to the micro tunnel exits would have the greatest potential to affect local air quality. A scenario has been modelled which represents peak emissions during this part of the construction programme, consisting of a point source representing the pipe-laying vessel and the two anchor handling vessels at the microtunnel exit point, plus a further point source 300 m further from the shore representing a Multi Service Vessel (MSV).

The point source emissions used in the assessment of the contribution to short-term pollutant concentrations have been allocated a release height of 20 m and an emission temperature of 200°C, and have used the emission rates presented in Table 9.20. The assessment of impacts on short term concentrations has taken into account the expected utilisation as a percentage of engine load of the shipping types to be employed through the calculation of an emission rate.
factored over one hour, and the use of a complete year of meteorological data for a situation which is likely to exist for less than 7 days per pipeline ensures a robust assessment of impacts.

The shipping emission sources described in Table 9.21 have been incorporated into the construction plant model described in Section 9.6.2.3, in order to enable an overall assessment of the impact of activities on short term pollutant concentrations to be made.

9.6.2.3 Modelled Diesel (Construction) Plant

During the Construction Phase of the Project it was considered necessary to model the emissions from some of the diesel powered plant within the Study Area. A scenario was selected which represents a peak period where a number of construction activities are taking place simultaneously, and this was modelled in combination with the shipping emissions described in Section 9.6.2.2. This scenario included the plant associated with the Microtunnelling, Landfall Facilities, Trench Excavation and Pipeline Installation activities. The construction of the Varvarovka bypass road, site preparation and reinstatement phases are forecast to take place outside of this period of peak activity, and have not therefore been included within the modelling and the impacts on local air quality would be lower.

Table 9.22 presents the numbers of construction used in the modelling of the construction phase.

</table>
As with vessels, mobile construction plant are not static sources which makes it difficult to model their impact on a particular receptors. In order to consider the impact on pollutant concentrations from diesel plant on a robust basis, each plant type has been modelled as a combined point source situated in a worst case location with regard to proximity to sensitive receptors. The emission source has been assumed to discharge at a fixed height of 3 m above ground level with a nominal discharge velocity of 5 m/s.

In addition to the mobile plant, the diesel generators have also been included as individual point sources within the ADMS 5 model. Each 250 kW generator (as listed in Table 9.19) was modelled with an individual stack with a discharge height of 5 m, diameter of 0.2 m, volume flux of 1.22 cubic metres per second (m$^3$/s) and temperature of 350°C. The generators for the microtunnelling plant are larger and the volumetric flow rates for these items have been scaled pro-rata. The emissions associated with landfall and nearshore construction plant have been calculated based on Non Road Mobile Machinery Stage IIIA emission rates and assuming a sulphur content in the fuel of 0.002% (Ref. 9.8).

Table 9.23 to Table 9.27 inclusive present the emissions rates used to calculate long-term (abbreviated to ‘LT’ in the tables) and short-term (‘ST’) pollutant concentrations. Long-term (annual mean) emissions take into account the utilisation rate of the construction plant and assume a working period of 10 hours per day (with no night time use), with the exception of the microtunnelling which is a 24 hour operation. The assessment of short-term impacts assumes an emission rate based on 100% continuous running, which is a conservative approach.

* NOx mass (expressed as NO2)

The diesel compressors used during the Pre-Commissioning Phase for cleaning, gauging and drying of each pipeline will be placed between the temporary PIG launcher / receiver located at a temporary construction area to the south of the landfall facilities. The compressor spread will require 80, 440 kW, combined compressor and booster units which will operate for up to 24 days per pipeline. Over this period, the compressors would operate 24 hours per day. The layout was modelled as four rows of 20 units, with a spacing of 5 m between each unit in the row and 10 m between each line of units. Emissions from multiple flues within a small area will in effect act as a single plume, and some recognition has been made of this within the model by combining the 80 individual stacks into 14 point sources. The ADMS software has evaluated the characteristics of the individual point sources and the spacing between them in order to determine the combined source parameters within the model.

Each 440 kW generator was modelled with a stack with a discharge height of 3 m, diameter of 0.25 m, volume flux of 2.14 m³/s and temperature of 400°C. The emissions rates used to calculate long-and short-term pollutant concentrations are presented in Table 9.27 (Ref 9.12).

### 9.6.2.4 Other Emission Sources

The assessment methodology used to assess other emission sources associated with other activities and phases of the Project, such as road traffic, rail, dust generation and fugitive venting, is sufficiently similar to the above or have been screened out of the assessment. Where necessary, this is detailed within the impacts section.

### 9.6.3 Assessment of Potential Impacts: Construction and Pre-Commissioning

#### 9.6.3.1 Introduction

The Construction and Pre-Commissioning Phase has the largest potential to impact on the sensitive receptors identified in Section 9.6.1.3. This is mainly due to the increase in vessel movements, plant and traffic emissions.

This section identifies and evaluates the significance of the various predicted impacts that are likely to arise in association with the Construction and Pre-Commissioning Phase of the Project.

Industry-standard mitigation measures are assumed to be incorporated in the pre-mitigation assessment (such as incorporating a small stack on the diesel generators for example, which are mentioned previously).

#### 9.6.3.2 Assessment of Potential Impacts (pre-mitigation)

This section identifies and evaluates the magnitude of the various predicted pre mitigation impacts that are likely to arise in association with the Construction and Pre-Commissioning Phase. Industry-standard mitigation measures are assumed to be incorporated in the pre-mitigation assessment. Additional mitigation measures required to minimise potential impacts are discussed in later sections.

**Construction Plant and Vessel Impacts Diesel Exhaust Emissions**

Impacts associated with the Construction Phase emissions from diesel plant and vessels have been combined into a single modelling scenario including modelled sources from:

- Construction plant and diesel generators in the landfall facilities;
- Construction plant and diesel generators used during the nearshore area (micro tunnelling); and
• Vessels related to nearshore activity.

Table 9.28 presents the results of the modelled Construction worst case scenario at the overall worst affected human health receptors, which are Receptor 2, located approximately 2.5 km east of the microtunnel exit points and Receptor 5, located approximately 500 m northwest of the microtunnel entry points and 1.5 km southwest of the landfall facilities at the southern boundary of a proposed residential development currently under construction. Receptor 5 is also situated on the boundary of the SPZ. The highest results predicted for these two receptors are presented in the Table 9.26. The predicted impacts are also the highest obtained from the modelling of five one year hourly sequential datasets, and as such likely to represent the highest impacts that could be experienced within the range of meteorological conditions at the Project Area.

The contour plots, or isopleths, showing the predicted impact on short-term and annual average pollutant concentrations are presented in Appendix 9.3: Contour Plots. Tables presenting the modelled impacts at all the selected discrete receptor locations are included in Appendix 9.4.

### Chapter 9 Air Quality

**Pollutant** | **Averaging period** | **Predicted impact on pollutant concentrations at worst affected sensitive receptor** | **Total predicted concentration, incl. baseline**
---|---|---|---
| | | µg/m³ | % of national limit | µg/m³ | % of national limit | % of PS* | % of national limit | % of PS* |
---|---|---|---|---|---|---|---|---|---|
Total PM | MPC | 27.4 | 5% | 5% | 177 | 35% | 35% |
| | APC | 0.5 | 1% | 1% | 141 | 94% | 94% |
PM$_{10}$ (assuming all PM is PM$_{10}$) | Maximum 24 hour | 6.5 | n/a | 13% | 147 | n/a | 294% |
| Annual average | 0.5 | n/a | 1% | 141 | n/a | 352% |
PM$_{2.5}$ (assuming all PM is PM$_{2.5}$) | Maximum 24 hour | 6.5 | n/a | 13% | 147 | n/a | 294% |
| Annual average | 0.5 | n/a | 2% | 141 | n/a | 564% |
Benzene (assuming all VOCs are benzene) | MPC | 38.4 | 13% | 13% | 38.9 | 13% | 13% |
| APC | 0.7 | 14% | 14% | 1.2 | 24% | 24% |

* PS = Project Standard

For CO, the predicted magnitude is less 5% of the project standard for both the short term and long term averaging periods, which is categorised as a negligible magnitude of change. According to the criteria presented in Table 9.13, such impacts can be regarded as **Not Significant**.

The maximum predicted impact on annual mean NO$_2$ concentrations is less than 25% of the Russian national standard and would not result in an exceedence of the APC limit. An impact of this magnitude in combination with a receptor of negligible sensitivity can be regarded to have a **Not Significant** impact. The predicted change in maximum 1 hour (IFC guideline) and 20 minute (Russian MPC) concentrations is more than 50% of the short term standard of 200 µg/m$^3$ and as such is categorised as a high magnitude impact. As this impact would occur in an area containing receptors of negligible sensitivity (residential properties outside of urban centres) (Table 9.16), it can be regarded as of **Low** significance. Notably, the predicted maximum 20 minute concentration is just within 80% of the MPC, which should be achieved at locations with relevant exposure within the SPZ. Furthermore, the modelled impact is primarily due to a modelled scenario whereby worst case shipping emissions lasting no more than 6 days at the closest point to shore, have been combined with the most adverse 1 hour period of
meteorological conditions over 5 complete years. As such, the impact reported is highly unlikely to occur in practice.

The predicted impacts on annual mean SO₂ concentrations amount to less than 10% of the applicable limits (where the total predicted concentration complies with the limit value) and is therefore of negligible magnitude, which when combined with the low sensitivity of the receptor, is **Not Significant**. The predicted change in maximum 20 minute (Russian MPC), 10 minute and 24 hour (IFC guideline) SO₂ concentrations is of a low magnitude, being between 10% and 25% of the criteria where the total predicted concentration complies with the limit value. For receptors of low sensitivity (Table 9.16), impacts of this magnitude result in an impact significance of **Low**.

The predicted change in annual mean and maximum 20 minute concentrations of total particulate matter are less than 10% of the Russian Federation limit values, and no exceedence of the criteria would occur. This would be a negligible magnitude impact, which results in a **Not Significant** impact.

The predicted change in annual mean concentrations of PM₁₀ and PM₂.₅, even when conservatively assuming that the entire particulate emission would be PM₁₀ and PM₂.₅ is of a negligible magnitude. Based on the assumption that PM₁₀ and PM₂.₅ concentrations exceed the national limits currently, this change can be regarded as **Not Significant**.

The predicted change in 24-hour PM₁₀ and PM₂.₅ concentrations is 13% of the IFC guideline, which is within the low magnitude of change category when the highly conservative assumption that baseline concentrations are in excess of the guideline across the Study Area is made. A low magnitude change at locations that are of high sensitivity due to baseline concentrations in excess of the project standard would give an impact of **Moderate** significance. However, for the reasons given in the baseline section, the assumptions made about existing PM₁₀ and PM₂.₅ concentrations are very likely to have considerably overestimated concentrations of these pollutants in a rural location such as the Study Area. In reality the baseline concentrations are highly likely to be well within the project standards, thereby giving a receptor of negligible or low sensitivity, which would result in a **Not Significant** or **Low** impact. Further monitoring will be undertaken in order to confirm that PM₁₀ and PM₂.₅ concentrations are well within the project standards as expected.

In terms of the EU limits for protecting vegetation and ecosystems, the highest modelled mean annual NOₓ and SO₂ concentrations at the boundary of the Utrish nature reserve are 0.38 µg/m³ in respect of NOₓ and 0.07 µg/m³ in respect of SO₂. This would be a negligible magnitude impact which results in a **Not Significant impact**.

**Emissions from Vessel Incineration Plant**

Some of the vessels to be employed in the Pipeline construction and pre-commissioning activities would use on-board incinerators to dispose wastes generated on board. The types and composition of the wastes are discussed in detail in Chapter 18 Waste Management, and would comprise:

- General Garbage (International Convention for the Prevention of Pollution from Ships (MARPOL) Annex V);
• Food (MARPOL Annex V); and
• Sludge/slops (MARPOL Annex I).

The total volumes of wastes to be burned are small. For nearshore vessels, the quantity of Annex I wastes that would be incinerated would be less than 75 kg per vessel per day. The quantity of Annex V materials would range from 22 kg per day (suction dredgers) to 210 kg per day (shallow water pipe-lay vessel). The average incinerator operating time would be from 0.5 hours per day (dredgers) to around 2 hours per day (shallow water pipe-lay vessel). The larger intermediate depth and deep water pipe-lay vessels would incinerate slightly higher quantities of Annex V general wastes (up to 600 kg per vessel per day), and the incinerators would operate for longer periods (up to around 7 hours per day).

The incineration plant to be used will be the International Maritime Organisation (IMO) and MARPOL compliant units provided as standard on Project vessels. The IMO specification (Ref. 9.11) for shipboard incineration plant sets out the operational controls, emissions standards, testing and certification requirements to be employed in the operation of such units.

Given the low volumes of wastes to be incinerated within IMO approved incineration plant on nearshore vessels, and the relative distance between offshore vessels and human sensitive receptors, it has therefore not been deemed necessary to model incinerator emissions, and the magnitude of impact is considered to be negligible.

Based on the predicted negligible magnitude the worst level of impact significance that would be expected is Low.

Construction Landfall Dust Generation Impacts

The movement of soils and rubble and vehicle traffic on unsealed roads during construction activities is anticipated to lead to the generation of fugitive airborne dusts. The occurrence and significance of dust generated by earth moving operations is difficult to estimate, and depends upon meteorological and ground conditions at the time and location of earth working, plus the nature of the operations being undertaken.

Any such dust generation also has the potential to lead to environmental and socio-economic impacts, if not properly mitigated. The potential impacts to humans of construction dust are two-fold: as a potential impact on amenity, and as having the potential to cause human health effects. Typically, a large majority of complaints against construction works are associated with the former, relating to deposition of dust on crops, windows, cars, and the outside of buildings. In terms of health, the smaller the dust particles, the more likely they are to be inhaled, leading to respiratory problems. Airborne particulate matter with a diameter of less than 10 µm represents the particle size fraction of greatest concern to human health.

Large dust particles (greater than 30 microns in diameter), which make up the greatest proportion of dust emitted from construction works, will largely deposit within 200 m of the working area. Intermediate-sized particles (10–30 microns) are likely to travel up to 200–500 m, although at large minerals working sites, for example, they have been recorded at distances of up to 1 km (Ref. 9.12). Particle deposition rates decrease rapidly on moving away from the construction source, due to gravitational settlement.
Similarly, airborne particulate concentrations also decrease on moving away from construction sources, due to dispersion and deposition. It is unlikely that PM$_{10}$ would travel more than 1 km from any construction works (Ref. 9.13) providing they are properly managed. Table 9.15 shows that there are only two residential receptors within 1 km of the construction spread: Receptor 5, a proposed residential development currently under construction, approximately 500 m northwest of the microtunnel entry points and 1.5 km south-west of the landfall facilities; and Receptor 1, a group of residential dwellings situated in the southern extremity of the nearby town Varvarovka, approximately 800 m north of the microtunnel entry points.

During the construction of the Varvarovka bypass access road, construction will take place close to receptors on the eastern edge of Varvarovka. Such operations would be relatively short term in nature as the construction plant would advance along the route of the road as construction progresses. Whilst there are sensitive receptors within 50 m of the road construction site, the implementation of good site practice and the stringent use of dust mitigation measures throughout all elements of the works would be capable of controlling emissions, to the extent that the effect of any impact will not be significant. In use, the access road would be sealed, meaning that significant dust arisings from passing traffic would be unlikely, provided the road surface is kept clean.

Further to the main construction area, a spoil transfer area may be created and used to the east of the Varvarovka bypass access road. The minimum distance between the transfer area and residential properties is around 250 m, meaning that deposition of larger size fractions of dust are unlikely to be significant at these locations provided that standard measures to control dust arisings are maintained. PM$_{10}$ can travel this distance; but given the mainly coarse and damp nature of the spoil material to be handled, it is not expected that a significant increase in PM$_{10}$ concentrations would occur, provided that measures to control the resuspension of road dusts are maintained within the spoil area and along the unsealed access road during operations in dry or windy conditions.

The Gazprom access road from the south would pass within 50 m of receptors on the southern edge of Varvarovka; however, traffic on this route is expected to be low (less than 50 vehicles per day of which more than half would be cars and light vehicles). Standard dust control measures for haul roads would need to be implemented on this route, but if they are correctly applied it is unlikely that a significant impact on baseline dust deposition rates or PM$_{10}$ concentrations would occur from this source.

In addition to distance between the source and receptor, wind speed and direction is another important factor in determining the significance of dust effects. Figure 9.4 reveals that the predominant wind direction is expected to be from the northeast to the southwest. More detailed analysis shows that the wind would blow from the microtunnel entry points towards Receptor 1 for approximately 21% of the time, and only 5% of the time towards Receptor 5 (which is the closer of the two receptors).

Overall, given the distances between the working areas and the nearest receptors, and the relatively low amount of time that the dust would be blown directly towards these locations, it is not expected that a significant impact on local PM$_{10}$ concentrations or dust deposition rates would occur, provided that good working practices are utilised to minimise dust generation at the construction sites, including where appropriate, dust suppression, covering of long-term
stockpiles where practicable and not undertaking exposed tipping activities during periods of high wind speeds blowing in the direction of the receptors. A negligible magnitude of change is expected to existing dust and PM$_{10}$ concentrations at these locations.

Taking into account the high sensitivity of human receptors to dust and particulate matter, the overall significance is considered Not Significant.

The vegetation in the immediate vicinity of the Project Area is not known to be sensitive to dust deposition. Juniper is slow growing with low levels of photosynthesis, and significant quantities of dust would not accumulate on the fine leaves. Vulnerable herbaceous species within woodland would also not be affected as the surrounding trees would rapidly attenuate any incoming dust emissions. Any material that is deposited would be washed off during periods of precipitation. Therefore, it is anticipated that flora close to the construction site would be subject to an impact that is Not Significant.

**Road Traffic Impacts**

There will be a number of additional road movements in the vicinity of the construction site to deliver workers and materials, which is outlined in further detail in this subsection.

It is proposed that all traffic will come from the main highway M25 about 10 km north of the landfall location and will be diverted around Gai Kodzor to the east and south of the town using the bypass constructed by Gazprom. To the east of Varvarovka traffic will then turn onto the site access road, which is around 35 m from the closest residential properties.

On the access route from the M25, the baseline annual average daily traffic (AADT) vehicle flow is around 5,100 vehicles through Rassvet, falling to around 3,800 vehicles to the north of Gai Kodzor. Around 15% of this traffic is heavy vehicles of greater than 3 tonnes gross vehicle weight (GVW). To the east of Varvarovka close to the turn off onto the site access road, around 4,200 vehicles currently use the western Varvarovka road per day. An estimated 10% of this constitutes trucks, with the remainder being cars and light vehicles. Based on the assumption that each pipeline is built in turn over a single continuous period, the peak construction traffic is expected to occur during Pipeline construction, between an estimated August 2014 and December 2014, lasting approximately five months. During peak construction approximately 260 vehicles would use the access route to the site from the M25 each day, leading to around 520 additional movements. At any times during the construction programme, less than 30 Project vehicles per day would use the main road through Gai Kodzor, none of which would be trucks or other heavy vehicles as these would use the bypass. From the south of Varvarovka, the impact on existing traffic movements would be small, less than 25 vehicles in total, most of which would be trucks.

Figure 9.6 displays the estimated profile for the following five phases of development: (1) Site preparation, (2) Microtunnelling, (3) Pipeline construction, (4) Landfall facilities, and (5) Reinstatement of the Pipeline route.
The trip generation associated with the Project will therefore lead to a noticeable increase in traffic along the designated site access route. Despite this, it is not anticipated to lead to a significant air quality impact, as discussed below.

The estimated emissions associated with these vehicle movements are presented in Table 9.29. This is based on the assumption that each road vehicle would make a 100 km round trip from Novorossiysk to the Landfall Facilities construction site, where it is assumed many of the road trips would originate. In reality, this is a worst case assumption as a large number of truck movements would actually originate at locations closer to the construction site.

Russia has implemented European standards for new diesel engine vehicles. The current standards for existing models are based on Euro III standards and apply to both manufactured and imported heavy-duty vehicles (the implementation date of Euro IV for all new vehicles was delayed until 2013). For the purpose of this assessment, it has been assumed the average vehicle would have emissions equivalent to units built between 2000 and 2006, which corresponds with Euro I emission legislation.

The impact of additional road traffic on local air quality in the vicinity of the access route has been screened using the UK DMRB screening tool (Ref. 9.6) to check the effect of this increase in emissions. Although this screening tool is based on a current UK fleet, it has been adjusted to 2000 conditions to best represent Euro I emission factors\(^7\), and using a conservative assumption that the peak trip generation would be sustained for an entire calendar year. The locations that have been assessed are:

- Rassvet, at the junction with the M25;
- South of Rassvet, at residential properties close to the access route;
- East of Varvarovka, in the vicinity of the closest residential properties to the northern construction site access road;
- In the vicinity of the closest residential properties to the Varvarovka bypass access road, SW of the main road;
- Within central Varvarovka; and
- To the south of Varvarovka, at residential properties near to the Gazprom access road turning.

Table 9.30 presents the estimated contribution of road traffic (at residential properties) to local pollutant concentrations for the two key pollutants of concern, NO\(_2\) and PM\(_{10}\). The results show that the change in road traffic flows associated with the Project would be **Not Significant** on local air quality, depending on whether the baseline concentrations currently exceed the air quality limits.

Complete.
The largest predicted changes in annual mean pollutant concentrations are predicted to occur in the area around Rassvet and the M25 junction, at residential properties close to the affected route. A change in NO$_2$ concentrations of around 3 µg/m$^3$ and a change in PM$_{10}$ of up to 2 µg/m$^3$ would take place. At the closest properties to the Varvarovka bypass access road, the change in annual mean NO$_2$ concentrations would be up to 2.2 µg/m$^3$. Monitoring of NO$_2$ in Gai Kodzor (Tube 3, Table 9.7) and Eastern Varvarovka (Tube 4, Table 9.7) suggests that baseline concentrations of pollutants are well below the annual mean Project standards (NO$_2$ 40µg/m$^3$) at locations outside of urban centres. The predicted change is less than 10% of the relevant annual mean air quality standards and is considered to be a negligible magnitude of change which is unlikely to lead to an exceedence of the criteria.

Within central Varvarovka, the change in roadside contribution to NO$_2$ and PM$_{10}$ concentrations is well below 1% of the annual mean criteria for NO$_2$ and particulate matter. This is considered a negligible magnitude of change (i.e. less than a 5% change in baseline concentrations).

In other areas, including in close proximity to the northern and southern site access roads, there would be a very small change in pollutant concentrations at sensitive receptors and hence would be Not Significant.

Taking into account the sensitivity of the receptors, which is high in urban areas, the overall significance of the impact is predicted to be Not Significant.

**Use of Port Facilities**

Existing port facilities at Novorossiysk are likely to be used for the operation of supply and refuelling vessels, temporary storage of construction materials, plant and a limited quantity of pipe sections. The port would also receive vessels wastes. The Port of Novorossiysk is in an existing industrial use area. There are residential areas within approximately 300 m of the port.

As such operations would take place as part of the normal on-going business of the port, any additional emissions which do occur would be considered negligible in comparison to the surrounding existing industrial uses. It has therefore not been deemed necessary to undertake any further assessment of the use of the port facilities, and the magnitude of impact is considered to be negligible.

**Pre-Commissioning Compressor Generator Impacts**

The assessment of impacts associated with the Pre-Commissioning Phase emissions have focussed on impacts due to emissions from the 80 compressor / booster units to be located to the south of the landfall facilities construction site. The level of activity associated with the operation of diesel construction plant and vessel movements would be well below that assessed in the main onshore Construction Phase, and as such these sources have not been included within the pre-commissioning model.

Table 9.31 presents the results of the modelled pre-commissioning scenario at the most affected human health receptor. The predicted impacts are the highest obtained from the modelling of five one year hourly sequential datasets, and as such likely to represent the highest impacts that could be experienced within the range of meteorological conditions at the Project Area.
The compressor / booster units are expected to operate for 24 days per pipeline, and the annual mean results presented below have been factored on the assumption that there would be a maximum of 48 days operation (2 pipeline pre commissioning periods) in any one calendar year.

A contour plot, or isopleth, showing the contribution of the operation of the compressor / booster units to short-term NO₂ is presented in Appendix 9.3.

</table>
For SO2, CO and particulate matter (including PM10 and PM2.5), the predicted impact on short term and long term concentrations is less than 5% of the selected criteria for both the short term and long term averaging periods, which is categorised as a negligible magnitude change. According to the criteria presented in Table 9.13, such impacts can be regarded as Not Significant.

The predicted impact on benzene concentrations is 4% of the long term standard and 28% of the short term standard, which are categorised as negligible and moderate magnitude changes respectively. According to the criteria presented in Table 9.13, such impacts can be regarded as Not Significant.

The maximum predicted impact on annual mean NO2 concentrations is 5% of the Russian national standard and would not result in an exceedence of the APC limit. An impact of this magnitude can be regarded as Not Significant.

The predicted change in maximum 1 hour (IFC guideline) and 20 minute (Russian MPC) NO2 concentrations is between 25% and 50% of the short term standard of 200 µg/m³ and as such is categorised as a moderate magnitude impact. As this impact would occur in an area outside of urban centres containing receptors of negligible sensitivity (Table 9.18), it can be regarded as Not Significant. The predicted maximum 20 minute concentration is within 80% of the MPC, which should be achieved at locations with relevant exposure within the SPZ.
9.6.3.3 Mitigation and Monitoring

Construction Phase Emissions

Fugitive dust is expected to only represent a potential short-term nuisance to exposed human receptors in immediate proximity to the construction site and will be controlled through the application of a series of good practice measures including, but not necessarily limited to:

Controlling fugitive dust emissions through:

- Personnel will be provided with awareness training in understanding the need to minimise dust and gaseous emissions from construction activities and practical ways to achieve this;
- A trained and responsible environment manager will be located on site during working times to maintain a logbook of instances such as visible dust plumes and detectable odour at the working site boundary, and carry out site inspections, particularly at the start of each new phase of works;
- Use of water as a dust suppressant where appropriate during dry weather and windy conditions;
- Implementation of an appropriate speed limit within the construction corridor;
- Vehicles will be cleaned regularly, including wheel washing before leaving site, in wet conditions;
- All loose material loads entering and leaving site will be covered where practicable;
- No bonfires will be lit onsite and no waste will be burned onsite;
- If soil is to be stockpiled long term then it will be covered where practicable or seeded and vegetated as appropriate; and
- RoW vegetation to be reinstated in line with the contractor restoration and reinstatement plan following installation of the pipelines.

Controlling Construction vehicle emissions through:

- Planning of operation schedules for construction machinery to exclude as far as possible transportation of irregular loads during certain busy periods;
- All site vehicles and plant will switch off engines when not in use; and
- As far as possible, the main equipment used during construction (main plant, diesel generators, etc.) shall conform to Stage III emissions standards. Priority is given to the equipment which ensures compliance with environmental standards and air protection requirements.

Controlling vessel emissions through:

- Minimising the use of vessels as far as practical and adhering to national and international legislation regarding fuels;
- Systematic monitoring of the condition and the adjustment of the fuel systems of ship equipment;
The main ship engines must be certified in compliance with the MARPOL 73/78 convention, and priority is given to the equipment which ensures compliance with environmental standards and air protection requirements;

Starting and operating according to manufacturer's recommendations and implanting a schedule of mandatory maintenance to ensure that equipment is functioning properly to minimise emissions; and

Maintenance services will monitor the malfunctions of internal combustion engine fuel systems and diagnosing them for the permissible level of harmful substance emissions released into the atmosphere.

The main mitigation for vessel emissions is the appropriate design of the emission stacks and the use of marine diesel oil (MDO) fuel with a low sulphur content.

A minimum 3 m high stack will be associated with the pre-commissioning diesel generators, and 10 m for the 4 MW heaters.

A monitoring programme will be set up to track annual emissions and identify pollutant concentrations at sensitive locations in the vicinity of the project. This will be discussed with the Russian Federation and shall adhere with national requirements for inclusion in the Project Environmental and Social Management Plan (ESMP) discussed in Chapter 22 Environmental and Social Management. It will include keeping an inventory of emissions based on actual plant or fuel usage, to calculate tonnes emissions per year, and ambient air monitoring at a number of receptors during key construction activities.

The ESMP will provide a compilation of mitigation measures outlined in this section, along with monitoring requirements.

**9.6.3.4 Residual Impacts: Construction and Pre Commissioning**

Table 9.32 presents a summary of the potential residual impacts to air quality arising from the Project during the Construction and Pre-Commissioning Phase following application of the identified mitigation measures. The Table also presents the pre-mitigation impact significance, before the measures presented in Section 9.6.3.3 are taken into consideration.

In summary, the pre-mitigation impact significance is generally Not Significant or Low and therefore has not required rigorous additional mitigation measures beyond normal Good International Industry Practice (as listed in Section 9.6.3.3); the residual impacts therefore remain the same.

There are no predicted residual impacts that are considered to be Moderate or High significance.

9.6.4 Assessment of Potential Impacts: Operational Phase

9.6.4.1 Introduction

The Operational Phase (including the Commissioning Phase and Full Operational Phase) is likely to have a much lower potential to impact air quality in the vicinity of the sensitive receptors identified in Section 9.6.1.1 than the Construction and Pre-Commissioning Phases discussed above. This is mainly due to the very limited vessel, plant and road traffic associated with this phase.

9.6.4.2 Assessment of Potential Impacts (pre-mitigation)

This section of the chapter describes the potential impacts associated with the Operational Phase of the Project.

Offshore and Nearshore Section Vessels

There will be a need to mobilise vessels for Pipeline inspection (and possibly for repair) during operation. Inspection is expected to be an infrequent event (initially annually), using Remote Operated Vehicles to inspect the underwater sections, lasting for only a short duration and using relatively few vessels. The bulk of the emissions will also occur offshore, away from onshore sensitive receptors.

Based on the relatively limited volume of emissions at locations away from onshore receptors the impact magnitude is considered negligible. The overall impact significance, when taking into account the magnitude of emissions and receptor sensitivity is Not Significant to Low depending on pollutant.

Onsite Plant Exhaust Emissions

It is anticipated that the activities and emissions from onshore site plant during operation (for maintenance or repair work for example) will be negligible and no significant air quality impacts will arise.

The overall significance when taking into account receptor sensitivity is Not Significant due primarily to the low volume of vented gas.

Equipment Losses and Venting

Non-combusted, fugitive emissions are inevitable from gas pipelines, arising from leaking valves and flanges during routine operation. These are usually negligible in magnitude (and are expected to be significantly less than venting that may be required during a planned shutdown which is discussed below) and, given the distance to the nearest sensitive receptors, should not cause any detectable change in concentrations. The impact is therefore considered Not Significant.

In addition venting episodes of natural gas and nitrogen from the landfall facilities during maintenance activities and pigging activities and facilities during gas filling (commissioning) will
occur. During operation, there will be a permanent 21 m high stack located just outside the landfall facilities to vent gas. The stack height has been pre-determined based on safety requirements in the workplace in order to protect workers at the facility from asphyxiation, to ensure adequate dispersion in the atmosphere, and to ensure that an explosive mixture is not present at ground level. There will be some occasional venting of gas during pigging, which will result in the release of small amounts of hydrocarbons, but this will only take place only once every five years on average.

Given that the vent stack has been designed in order to provide for the safe venting of gas during a shutdown situation, it is not expected that this operational venting would pose a risk to the health of residents at nearby receptors given their distance from the vent. Due to the very low concentration of hydrogen sulphide (H₂S) in the gas, perceptible odour impacts on the amenity of residents are unlikely. The vent stack for releases of natural gas has been designed as 21 m in height for the safety reasons discussed in the Safety Design Philosophy for Landfall Stations; this is considered more than sufficient to avoid any significant impacts to nearby sensitive receptors. The impact is therefore considered Not Significant. The volume of gas vented during operation will also be monitored and reported annually.

9.6.4.3 Mitigation and Monitoring

In conclusion, no Moderate or High impacts are predicted to local air quality during the Operational Phase of the Project and it is not considered necessary to conduct monitoring or identify receptor specific mitigations strategies at this point in time. A planned maintenance and inspection programme would by necessity be necessary to minimise the potential for fugitive emissions to occur on safety grounds, and this need would also ensure that fugitive emissions to air would also be virtually eliminated.

The standard Good International Industry Practices outlined in Section 9.6.3.3 will be followed for any onshore and offshore plant and vessels required during the operational phase for maintenance and repair work.

9.6.4.4 Residual Impacts: Operational Phase

Table 9.33 presents a summary of the potential residual impacts to air quality arising from the Project during the Commissioning Phase and Full Operational Phase following application of the identified mitigation measures. Table 9.33 also presents the pre-mitigation impact significance, before the measures presented in Section 9.6.3.3 are taken into consideration.

It is not anticipated that any significant impacts to the ambient air quality conditions will arise from the Operational Phase of the Project; the emissions during operation are anticipated to be of negligible magnitude, resulting in an effect that is Not Significant.

9.6.5  **Assessment of Potential Impacts: Decommissioning Phase**

9.6.5.1  **Introduction**

The planned Project lifetime is 50 years, within which there may be changes to statutory decommissioning requirements, as well as advances in technology and knowledge.

The eventual decommissioning requirements will be taken into account several years prior to decommissioning by ensuring that a range of possible options will be available.

9.6.5.2  **Assessment of Potential Impacts (pre-mitigation)**

At this stage in the Project, the full extent of the decommissioning requirements is not known. However, it is likely that the impacts will be of a similar nature, albeit of a lesser magnitude, than those presented for the Construction Phase. The primary tasks to be undertaken would be associated with:

- The demolition of facilities and infrastructure;
- Equipment and vehicle movements;
- Earthworks; and
- Removal of wastes from site.

Given the timeframe involved there is also considerable uncertainty associated with what the baseline conditions will be like in 50 years’ time, and whether the receptor sensitivity is likely to differ. Generally, it is expected that vehicle emissions will improve through technological advancements, although this would be offset to some extent by a net increase in vehicle movements in the area in line with population growth. Overall, it is considered that impacts could be controlled to an acceptable standard during the Decommissioning Phase. An assessment, to be prepared at the time decommissioning takes place, will be conducted to assess the impacts in the light of prevailing air quality conditions and consider appropriate mitigations.

9.6.5.3  **Mitigation and Monitoring**

The potential impacts during the Decommissioning Phase would be no worse than that of the Pre-Commissioning and Construction Phases. It would be possible to design mitigation and monitoring measures to control fugitive dust arisings such that significant impacts would not occur at sensitive receptors, and the measures outlined in Section 9.6.3.3 will therefore be relevant.

9.6.5.4  **Residual Impacts: Decommissioning Phase**

As detailed above, an assessment will be produced at the time of decommissioning. At the current time, it is not anticipated that any significant impacts to the ambient air quality conditions will arise from the Decommissioning Phase of the Project.
9.6.6 Country Emissions of GHG and Pollutants

An important component to the assessment is the calculation of the tonnes emissions of greenhouse gases and pollutants emitted by the Project during construction and operation. Although there are no international, national or Project standards against which to assess these emissions, they can be compared against the existing regional or national emissions and a judgment made as to the scale and importance of these emissions.

Furthermore, the IFC Performance Standard 2012 (Ref. 9.14) states that:

“...for projects that are expected to or currently produce more than 25,000 tonnes of CO₂-equivalent annually, the client will quantify direct emissions from the facilities owned or controlled within the physical project boundary”.

According to the EIA for the Krasnodar 410 megawatt (MW) combined cycle gas turbine (CCGT) Combined Heat and Power (CHP) Plant (Ref. 9.15) the key emissions sources in the Anapa/Krasnodar region are road vehicles which contribute an estimated 92% of total atmospheric emissions in the Krasnodar region. Almost all of the remaining approximately 8% of emissions are from industrial sources, including Krasnodar Thermoelectric Power Plant (Krasnodarskaya TETs), AO Novorostsement in Novorossiysk, and the Krasnodar CCGT CHP Plant mentioned above.

The EMEP Centre on Emission Inventories and Projections (CEIP) presents the following country-wide emissions for Russia in 2010 (the latest year of available data) (Ref. 9.5):

- 1,314 thousand tonnes per annum of SO₂;
- 2,421 thousand tonnes per annum of NOₓ; and
- 10,122 thousand tonnes per annum of CO.

The United Nations Framework Convention on Climate Change (UNFCC) provides the following country-wide data for Russia during 2010 (Ref. 9.16):

- 950 million tonnes per annum of CO₂; and
- 600 million tonnes per annum of non-CO₂ GHGs.

Emissions data could not be identified on a regional basis for the Anapa/Krasnodar region.

Table 9.34 to Table 9.37 present the estimated emissions for all vessels associated with the nearshore and offshore Pipeline installation operations. It is conservatively assumed that up to 2 pipelines would be constructed per year.

In the absence of a detailed programme of works at this stage of the Project it has been assumed that all vessels associated with a particular area will be operating simultaneously. This is particularly unlikely for the nearshore area, which spans a relatively short distance and is more likely to have specialist vessels being used in succession as each sub-task is completed rather than simultaneously.

Full details of methodology and calculations for total emissions are provided in Appendix 9.5.

Table 9.38 presents the total emissions and emissions in tonnes per year (equally split between 3 years) during the Construction and Pre-Commissioning Phase and represents the sum of Totals for all pipelines as presented in Tables 9.34, 9.35, 9.36, and 9.37.

The Construction and Pre-Commissioning phase of the Project is predicted to increase national reported emissions of NO\(_x\) by 0.2%, most of which is attributed to the offshore vessels. The expected increase in PM, SO\(_2\), and NMVOC emissions is expected to be less than 0.2% of national emissions. As CO\(_2\) emissions are expected to exceed 25,000 tonnes per year a monitoring plan will be put into place to quantify direct emissions from the Project, as outlined in Section 9.6.3.3.

9.7 Unplanned Events

There is the potential for unplanned releases of non-combusted gas from the landfall section of and offshore sections of the Pipeline. The only possible sources of large scale releases of gas into the atmosphere would be the result of a pipeline rupture (or blowout). Statistically, a
pipeline rupture is a very rare event and the probability of such an extreme situation is very low.

In the unlikely event of rupture of one of the Project pipelines during operation a shutdown sequence would be initiated from the pipelines control room.

During operation, there will be a permanent 21 m stack located just outside the landfall facilities. This will be used to depressurise the landfall facilities during a planned shutdown, for example to allow repairs to be undertaken, or (if absolutely necessary) to vent gas from the offshore pipelines to allow repairs to be undertaken in the event of a leak.

The vented gas composition is presented in Table 9.39.

</tr>
</tbody>
</table>

Ambient air quality limits have not been set by the Russian Federation or IFC for the compounds listed in Table 9.39. Due to the very low concentration of H₂S in the gas, perceptible odour impacts on the amenity of residents are unlikely. The vent stack has already been designed as 21 m in height for safety reasons; this is considered more than sufficient to avoid any significant impacts to nearby sensitive receptors. The volume of gas vented during operation will also be monitored and reported annually.

Further discussion on unplanned events is presented in Chapter 19 Unplanned Events.

### 9.8 Cumulative Impact Assessment

The cumulative impacts associated with the Project relating to air quality are assessed in Chapter 20 Cumulative Impact Assessment.
9.9 **Conclusions**

The Pre-Commissioning and Construction Phase will result in the majority of the Project’s emissions to the atmosphere and therefore have the greatest potential to affect air quality. In summary, the pre-mitigation impact significance is generally **Not Significant** or **Low** and therefore has not required rigorous additional mitigation measures beyond normal Good Industry International Practice (outlined in Section 9.6.3.3). The residual impacts, therefore, remain at the same level of significance.

There are no predicted impacts considered to be of High significance to air quality.

The impact on the Utrish National Reserve will be **Not Significant** due to the negligible magnitude of change predicted for this high sensitivity receptor. Emissions to air during the Commissioning and Operational Phases will be minimal. Consequently it is not anticipated that any significant impacts to the ambient air quality will arise from the Commissioning Phase and Full Operational Phase. The impacts during operation are anticipated to be of negligible magnitude, resulting in an effect that is **Not Significant**.

At this stage, the full extent of the decommissioning requirements are not known; however, at the current time, it is not anticipated that any significant impacts to the ambient air quality conditions will arise from the Decommissioning Phase of the Project.

The impacts relating to the construction and pre-commissioning activities are temporary in nature, and will cease at the end of this phase of works. No significant impacts are expected during the Operational Phase of the Project.

10 Noise and Vibration

10.1 Introduction

This chapter presents an assessment of the likely impacts of noise and vibration generated by the Project on human receptors. Assessment of noise and vibration impacts on ecological receptors is addressed in Chapter 11 Terrestrial Ecology and in Chapter 12 Marine Ecology.

Both noise and vibration may impact the health and wellbeing of human receptors particularly with regards to disturbance of relaxation and sleep (Ref. 10.1). This could lead to elevated stress levels and other health impacts (Ref. 10.1). As such, both regional and international legislation and guidance have been used when assessing noise and vibration at sensitive receptor locations.

Aside from health impacts, noise and vibration can also impact community areas such as cemeteries, beaches and public open spaces, where elevated noise levels can be a nuisance.

This chapter characterises the existing ambient noise and vibration environment of the closest receptors to the Project Area (Section 10.3). Calculations have been undertaken to determine the noise and vibration levels that will be generated by the Project at sensitive receptors. The resulting noise and vibration assessments have been used to determine potentially significant impacts in terms of relevant international and Russian national standards and guidance. Where significant impacts are likely to occur, suitable mitigation measures are identified.

This chapter has been prepared in tandem with Chapter 14 Socio-Economics. Where relevant, Chapter 14 Socio-Economics draws upon the findings of this noise and vibration assessment.

10.2 Scoping

The scope of this noise and vibration impact assessment was defined through a scoping process that identified sensitive receptors and potentially significant impacts related to the Project. Key steps in the scoping process comprised:

- A review of the Project details to identify activities with the potential to generate significant levels of noise and vibration;
- Identification of sensitive receptors within the likely noise and vibration Zone of Influence (Section 10.3) through a review of secondary data (Section 10.4), a review of studies undertaken for the South Stream Offshore Pipeline and using professional expertise; and
- A review of relevant national and international legislative requirements and standards and guidelines for financing to ensure legislative and policy compliance.

An Environmental Issues Identification (ENVIID) process was undertaken to assist in the identification of impacts and receptors. During the ENVIID process, each activity was examined, drawing upon the experience of technical specialists and their understanding of the extent and nature of the Project Activities and the natural environment, to understand:
Chapter 10 Noise and Vibration

- How activities may give rise to noise and vibration impacts; and
- Which receptors would potentially be impacted by each activity and the potential significance of each impact.

The output of the ENVIID was an ENVIID register, which identified the various elements of the Project and their interaction with, or potential impact on, sensitive receptors.

10.3 Spatial and Temporal Boundaries

The Project Area is defined in Chapter 1 Introduction.

The Project will consist of the following phases: Construction and Pre-Commissioning, Operational, and Decommissioning Phase. The impact of each of these has been considered separately, and the assessment of the impact has considered the duration of each phase.

Sources of noise and vibration during the Construction Phase will include vehicles, vessels, plant and machinery used to undertake earthworks, pipeline fabrication and laying, construction of the microtunnels, and offshore dredging works at the microtunnel exit locations.

The Pre-Commissioning Phase will involve cleaning, gauging and hydro-testing of the Pipeline. During hydro-testing, pumps that provide the necessary testing pressure after flooding the Pipeline are likely to generate noise.

Sources of noise and vibration during the Operational Phase will be limited to activities associated with maintenance and repair, vessel operation, noise from vehicles, and unplanned events.

Decommissioning activities are not anticipated to give rise to higher noise levels than the Construction Phase.

The temporal boundaries of the impacts related to each phase are defined by the duration of each activity associated with the phase. All the sources of noise and vibration associated with the Project are temporary in nature and no noise and vibration will be generated that will last beyond each phase.

The spatial boundaries of the impact assessment of each phase will be defined by the presence of terrestrial receptors that are sensitive to noise and vibration resulting from the Project Activities. These include present and proposed human receptors, such as residential properties, and any sensitive ecological areas. These are identified and described in Section 10.6.1.3. Thus, sensitive terrestrial receptors closest to the Project Activities define the Study Area.

The applicable standards that have been used during the impact assessment (Section 10.6.1.4) include Russian noise and vibration limits for day and night-time periods. These standards apply absolute noise and vibration level criteria at sensitive receptors.

For the purpose of the noise and vibration assessment, two study areas have been defined and are referred to as follows:

- The Study Area comprises the landfall and the nearshore sections of the Project and encompasses terrestrial receptors sensitive to noise and vibration located in close proximity
to these locations (Figure 10.2). Marine receptors are not included in the Study Area as these are discussed in Chapter 12 Marine Ecology; and

- The Wider Study Area comprises the Study Area along with the port at Novorossiysk, and includes representative receptors in proximity to the proposed access roads used for the transportation of material from the port to the landfall section. Whilst a final decision on the use of the Novorossiysk port has not been made at this point in time, it is considered to be a fair representation of a potential scenario which defines the Wider Study Area.

As this chapter is concerned only with effects on terrestrial noise and vibration receptors, a list of impacts which are excluded from assessment in this chapter is included below:

- The impact of occupational noise and vibration on the employees in the Project team. Occupational health and safety is discussed in Appendix 15.1: Occupational Health Appendix;
- The impact of noise on ecological receptors. This chapter provides the baseline noise levels at ecological receptors, and the noise levels that will be present at them due to the Project Activities. These are provided for information only, and are used to determine the magnitude of impact and significance of effect in Chapter 11 Terrestrial Ecology;
- The impact of offshore works (i.e. those beyond the nearshore) as these will have no impact on terrestrial noise and vibration receptors, owing to the considerable distance and resulting attenuation of noise and vibration levels;
- The impact of underwater noise and vibration which is discussed in Appendix 12.3: Underwater Noise Study; and
- The impact of vibration on indirect human receptors, such as infrastructure, livestock and fisheries. The criteria for impact magnitude on human receptors, such as residential, are much more stringent than those that could be applied to indirect human receptors. Hence the assessment of the impact on human receptors will be the worst case, and the significance of the impact on indirect human receptors will be lower than that for human receptors.

The Wider Study Area for noise and vibration, therefore, incorporates the sensitive human receptors in proximity to the landfall and nearshore sections of the Project (Figure 10.2), the port, and the access roads that will be used for the transportation of material to the landfall section.

### 10.4 Baseline Data

#### 10.4.1 Methodology and Data

Baseline noise and vibration data are necessary to provide a description of the current ambient conditions at receptor locations. The secondary data review, gap analysis and further baseline monitoring that have been undertaken are discussed within the following sections.
10.4.2 Secondary Data

No baseline information regarding the ambient noise and vibration characteristics at sensitive receptor locations throughout the Wider Study Area was available at the Scoping Stage\(^1\). This was not unexpected given the rural and semi-rural nature of the Wider Study Area.

There are a number of development proposals in the area; however, assessments and reports\(^2\) could not be obtained at the time of baseline review.

Consequently, no secondary data was identified for any of the sensitive receptor locations within the Wider Study Area. Baseline surveys were therefore scoped and planned.

10.4.3 Primary Data and Baseline Surveys

Baseline surveys were undertaken in December 2011, December 2012, June through July 2013 (Ref. 10.2 and 10.3), and September / October 2013 to characterise the ambient noise environment within the Wider Study Area. The noise survey locations are shown in Figure 10.1. The measurements were taken in accordance with the requirements of the standards and legislation adopted.

Given that many of the identified noise monitoring locations are representative of remote properties, and that there were no identifiable sources of vibration, vibration baseline monitoring was not undertaken at all locations. Baseline vibration monitoring has been undertaken at four of the monitoring locations, 10, 12, 22 and 23. These locations were selected for baseline vibration monitoring owing to their proximity to the existing road network, which has the potential to result in ground borne vibration from passing vehicles.

During the baseline surveys a number of noise parameters were measured, in order to provide a detailed understanding of the variability of the ambient noise levels at the monitoring locations. The most important parameters, because of their use in the Russian legislation, were considered as follows:

- \( L_{Aeq} \) - Equivalent continuous A-weighted sound pressure level over a given period of time (i.e. the single continuous sound level that conveys the same acoustic energy as a variable noise source over a given period of time); and
- \( L_{A_{max}} \) - The maximum A-weighted sound pressure level over a given period of time (i.e. to the human ear, the maximum sound level recorded in a given time).

The vibration monitoring surveys at the identified receptor locations measured the ground borne vibration in terms of the acceleration (mm/s\(^2\)) as defined within the Russian legislation.

---

\(^1\) Peter Gaz report on 'Complex Engineering Surveys...' (2011, Ref. 10.2) reviewed available secondary data, and concluded that there were no Project-relevant secondary data for noise and vibration. Consequently, primary data were collected specifically for the Project.

\(^2\) Although these reports were not obtained at the time of baseline review, it is unlikely that they would have contained valuable secondary data; Russian standards rely on absolute noise level criteria, and therefore baseline ambient surveys of noise and vibration are not required for the acceptability assessment of most developments.
Received noise within the Wider Study Area varies significantly depending upon the location of the receptor. In particular, the proximity of the receptor to urban development is a defining factor. Two general receptor types with associated noise climates were identified:

- Rural Residential (and Ecological Receptors) - the noise climate outside of the major residential areas is not dominated by any one noise source but is instead made up of road traffic noise (from the inter village roads), ecological noise (primarily bird song), and meteorological noise (primarily wind through trees); and
- Urban Residential Receptors - the dominant noise source in urban areas, such as Varvarovka, is road traffic noise. Other significant noise sources include aircraft, construction activities, and operation of industrial and commercial facilities.

The baseline surveys included measurements of the day (0700 – 2200), and night (2200 – 0700) noise levels. The survey locations were selected considering both the location of human settlements and isolated residents, as well as key potential ecological receptors in the area immediately surrounding the proposed Pipeline corridor or in proximity to the access road and Varvarovka bypass road. A summary of the baseline measurements is provided in Table 10.1.

The measured ground borne vibration levels for the day (0700 – 2200), and night (2200 – 0700) time periods are summarised in Table 10.2.

10.4.4 Data Gaps

The primary baseline data are considered adequate to facilitate a robust assessment of existing ambient noise and vibration levels at key human receptors within the Wider Study Area. No data gaps exist that could limit the assessment of the impacts associated with the Project.

10.5 Baseline Characteristics

10.5.1 Baseline Summary

Details of the baseline ambient noise surveys (Ref. 10.2 and Ref. 10.3) are presented below in Table 10.1.

The measured noise levels are shown to reach or exceed the Russian daytime noise limit (Ref. 10.4) for residential areas (55 dB L_{Aeq}) at measurement points 2, 3, 6, 7, and 21. All other positions are below the limit.

The measured night-time noise levels are shown to reach or exceed the Russian noise limit (Ref. 10.4) for residential areas (45 dB L_{Aeq}) at measurement points 1 to 10 (inclusive), 12, and 21. All other positions are below the limit.

It is considered that, for the sites sampled, the main noise sources were:

- Road traffic;
- Ecological noise (e.g. bird song); and
- Meteorological processes (e.g. wind in vegetation).
This is reflected in the $L_{A\text{Fmax}}$ results (Table 10.1), which are consistent with passing of vehicles as likely sources of the maximum noise levels recorded.

The measured vibration levels are presented in Table 10.2.

The measured vibration levels are shown to reach or exceed the Russian vibration limit (Ref. 10.5) for residential receptors ($4 \text{ mm/s}^2$) at positions 10 and 23 during the night, and at positions 22 and 23 during the day. These levels were likely due to the vibration generated by the nearby road traffic. It should be noted that the Russian vibration criteria do not distinguish different limits for day and night time periods.

10.6 Impact Assessment

10.6.1 Impact Assessment Methodology

The assessment of potential noise and vibration impacts took into consideration applicable international standards, Russian national standards and recognised Good International Industry Practice (GIIP) regarding the control of environmental noise and vibration.

The closest human receptors to the Project Activities have been identified within the Wider Study Area to define the spatial scope of the assessment; as defined in Section 10.6.1.3. The sensitivities of individual receptors have been categorised by their nature using the criteria in Table 10.6 to help determine the potential significance of effects.

The assessment of impacts has been undertaken by identifying and evaluating a range of activities and scenarios that are likely to occur throughout the phases of the Project. The key activities likely to generate noise and vibration during each of the Project phases are included below in Table 10.3.

It is important to note that the methodology has been designed specifically to assess noise and vibration impacts upon a recipient population and cannot be applied to the assessment of occupational noise and vibration effects associated with the Project works. Occupational health and safety is discussed in Appendix 15.1.

N - Noise, V - Vibration

**10.6.1.1 Impact Assessment Criteria**

Criteria have been developed for assessing the potential impacts of noise and vibration from the Construction and Pre-Commissioning, Operational and Decommissioning Phases of the Project, and include impact magnitude and receptor sensitivity. The impact significance matrix in Chapter 3 Impact Assessment Methodology is used to determine the significance of each impact.

Sensitive human receptors have been identified (Section 10.6.1.3, Table 10.5) in proximity to the proposed Pipeline route, potential port and along construction traffic routes. Human receptors have been classified based on their likely sensitivity to noise and vibration impacts.

Specific ecological receptors have been identified in proximity to the Pipeline route. No assessment of the potential impacts on ecological receptors has been addressed within this chapter, although predicted noise levels are presented. The assessment of such impacts is considered within Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology.

Impacts have been assessed and classified using the appropriate noise level criteria as described in Chapter 2 Policy, Regulatory and Administrative Framework and Section 10.6.1.4.

**10.6.1.2 Receptor Sensitivity**

The sensitivity of receptors to noise and vibration is primarily dependent upon the activities which take place at the receptor location. Locations where people rest or sleep are considered to be more sensitive to noise and vibration than industrial areas. This approach is supported by the applicable Russian noise legislation (Section 10.6.1.4), which delineates standards based on the nature of the potentially affected receptors and the time at which the impact may arise (e.g. night or day). A combination of professional judgement, GIIP experience and Russian noise and vibration legislation (Section 10.6.1.4) has been used to develop noise and vibration receptor sensitivity categories as shown in Table 10.4.

10.6.1.3 Receptor Identification

The nearest human receptors (and ecological receptors for the purpose of Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology) were identified through use of available aerial photography and field surveys. It is considered that the selection of the closest sensitive receptors to the Project Activities will reflect the largest impacts, as noise and vibration levels will attenuate with greater distance.

The proposed pipelines cross under the coastline approximately 1 km to the north of the Shingari holiday complex and 1 km to the south of Varvarovka. The pipelines then proceed in a northeast direction for approximately 2.5 km where they terminate at the proposed landfall facilities.

In addition to Varvarovka and the Shingari holiday complex, residential dwellings are located to the south of the proposed Pipeline route.

Receptor 8 is representative of the closest residential receptors located to the south of the Pipeline corridor. The settlement of Sukko is located to the south of the Pipeline corridor at a distance of approximately 3 km. It is considered that achieving the noise level criteria at Receptor 8 would ensure that noise levels would be well below the criteria at Sukko, owing to its greater distance from the Pipeline corridor, and the topographical screening from the inter-lying hills.

A description of the identified receptors used for the assessment and corresponding assigned sensitivities are presented in Table 10.5 and shown on Figure 10.2.

Receptor 5 is representative of a site for proposed residential use, located at a distance of approximately 430 m to the northwest of the microtunnels. This site has been considered within the assessment as having a negligible sensitivity, as it is anticipated that the site will not be developed and occupied during the Construction Phase of the Project. Consequently, it is anticipated that there will be no residential receptors at this location during the Construction Phase.
Receptors 13 and 14 are representative of the Varvarovka village cemetery and Gai Kodzor War Memorials, respectively. Russian legislation does not stipulate noise levels for such land uses, and therefore noise levels are not regulated at these locations. However, people visit these sites during the day and evening periods and such sites may be used for services and burials. Therefore, these locations have been considered as receptors with a high sensitivity within this assessment; the sensitivity classification assigned for cemeteries and war memorials is the same as for residential dwellings.

Receptors 9-12 (inclusive) are identified as ecological receptors. The sensitivity of specific ecological receptors will be dependent upon the species affected. A diverse range of fauna has been identified within the area surrounding the proposed Pipeline including mammals, reptiles and avian species. Sensitivities have therefore not been assigned to ecological receptor locations; receptor sensitivity and impact significance for ecological receptors is discussed under Chapter 11 Terrestrial Ecology.

</tr>
</tbody>
</table>

The Russian regulations (Ref. 10.4) provide a more stringent approach to the limiting of noise than that given in the IFC General EHS Guidelines (Ref. 10.6) as there is no allowance for elevated noise levels where the prevailing ambient noise climate is already over the prescribed noise limit. The Russian standards also incorporate limits within each octave band level, in addition to a limit value on the maximum noise level $L_{A\text{max}}$. Therefore, as the Russian regulations provide the most stringent criteria from the standards and guidance applicable, these have been adopted for the purposes of assessing noise impacts. The noise level criteria from page 9, Table 3 of the Russian regulations (Ref. 10.4) are reproduced below in Table 10.7.

Areas immediately adjacent to hospital and sanatoria | 07:00 – 23:00 | 31.5: 83 | 63: 67 | 125: 57 | 250: 49 | 500: 44 | 1k: 40 | 2k: 37 | 4k: 35 | 8k: 33 | 45 | 60
| 23:00 – 07:00 | 31.5: 76 | 63: 59 | 125: 48 | 250: 40 | 500: 34 | 1k: 30 | 2k: 27 | 4k: 25 | 8k: 23 | 35 | 50

It should be noted that according to Note 2 which accompanies the above Russian regulations (Ref. 10.4), the equivalent and maximum noise levels for noise generated by motor vehicles and railway transport are allowable at levels 10 dB(A) above the limit stipulated. However, it is understood that this limit is solely used for the purposes of noise from railway transport, and noise from motor vehicles should instead be assessed against the noise criteria given in Table 10.7. Therefore, Note 2 has not been considered in the assessment for the impacts of noise from construction equipment and vehicle movements; a more conservative appraisal of the potential noise impacts has thus been undertaken.

The above standards were considered to develop impact assessment criteria compliant with Russian legislation and which can be meaningfully applied to the Project.

As the Russian legislation defines a single absolute noise level limit, it has been necessary to develop noise level criteria that can be applied to define the “high” to “not significant” impact magnitudes. It is considered that as the broadband daytime (55 dB(A)) and night time (45 (dB(A)) noise levels correspond to the WHO levels to prevent serious annoyance and to prevent sleep disturbance during the night time with an open bedroom window, respectively, these noise levels are attributed to correspond to a “low” impact magnitude.

The defined absolute noise level limits apply solely to noise emitted by the Project, and have no regard to prevailing baseline noise levels. It has been established that the prevailing ambient noise climate at a range of receptors already exceeds the absolute criteria. These exceedances are considered to be part of prevailing baseline environment and are not as a result of activities associated with the Project. Therefore, it will be necessary to attribute the noise from activities associated with the Project at these locations in the absence of the prevailing ambient noise. This issue will be further detailed within the overarching Monitoring Programme.

Adoption of the absolute noise level criteria and applying these to the noise from the South Stream Offshore Pipeline operations only will ensure that there is no significant change in the noise climate where prevailing ambient noise levels may exceed the limit. In such circumstances where the ambient noise climate may exceed the adopted day and night time limits, the IFC guidelines suggest that the overall change in noise level should be limited to no more than 3 dB(A). Adopting the Russian legislation noise limits and applying these to noise from the South Stream Offshore Pipeline operations will ensure that, where prevailing ambient noise levels are
greater than the limit, the resulting change in noise level will be no more than 3 dB(A), and
therefore compliant with the IFC guidelines.

It should be noted that the IFC guidelines define the daytime period as 07:00 to 22:00 hours,
and the night time period as 22:00 to 07:00 hours. However, the Russian regulation Sanitary
Norms specify the daytime period as 07:00 to 23:00 hours, and the night time period as 23:00
to 07:00 hours. Therefore the IFC guidelines time periods are considered to be slightly more
onerous as they specify a slightly longer night time period. Therefore, for the assessment of the
noise impacts the IFC guideline time periods for day and night time have been adopted, thereby
ensuring a worst case approach to the assessment.

The development of the noise impact magnitude classifications has also considered human
perception to changes in noise levels. A 3 dB(A) change in noise level is only just perceptible to
the human ear. Therefore, noise level bands covering 5 dB have been adopted where changes
in the corresponding noise level would be clearly perceptible to any receptors. The adopted
noise bands corresponding to defined impact magnitudes are shown in Table 10.8.

10.6.1.5 Impact Magnitude

Table 10.8 defines the magnitude of noise impacts on human receptors during all Project
phases. The limit values and categorisation criteria are based on applicable noise legislative
requirements and guidance. Russian standards and legislation do not differentiate between long
and short duration noise sources affecting residential receptors. Therefore, the magnitude of
impacts has been developed on the absolute noise level criteria within these standards.

The adopted vibration criteria have been derived from the above limits and are based upon the vibration velocity. For vibration velocities below the criterion of 0.11 mm/s the resulting levels are unlikely to be perceptible to human subjects. Therefore, for vibration levels below 0.11 mm/s, the impact magnitude is classified as being negligible. Vibration velocities less than 1 mm/s are generally tolerable by human subjects for short-term construction operations, where the residents are kept informed of the progress of such works (Ref. 10.7). Therefore, for vibration velocities below 1 mm/s the impact magnitude is categorised as low. At vibration velocities of 10 mm/s, there is the potential for superficial damage to building structures, for example cracks may appear in plaster. Therefore, for vibration velocities up to 10 mm/s the impact magnitude is classified as being moderate. For vibration velocities of 10 mm/s and above the impact magnitude is classified as being high. The above criteria have been used to derive the vibration magnitude criteria presented in Table 10.10.

The adopted criteria for construction vibration impact magnitudes are shown in Table 10.10. The laying of the Pipeline below ground and the relatively low levels of vibration anticipated from gas flow through the Pipeline or pigging activities, coupled with the offshore exclusion zone that will prohibit certain types of development within 410 metres of the Pipeline corridor have been collectively considered and it is concluded that the resulting potential impacts from operational vibration will be negligible. As there are no identified significant sources of ground borne vibration during other phases of the development, vibration has not been considered for other phases.

10.6.1.6 Modelling Methodology

Noise predictions have been carried out using International Organisation for Standardisation (ISO) Standard 9613, Acoustics – Attenuation of Sound during Propagation Outdoors (Ref. 10.8). The propagation model described in Part 2 of this standard provides for the prediction of sound pressure levels based on either short-term downwind (i.e. worst case) conditions or long-term overall averages. For a downwind condition (for wind blowing 1 to 5 m/s from the proposed site towards the nearby receptors) worst-case noise levels will occur. When the wind is blowing in the opposite direction, noise levels may be significantly lower than those predicted. The ISO propagation model calculates the predicted sound pressure level by taking the source sound power level for each source and subtracting a number of attenuation factors according to the following:

Predicted Noise Level = LWA + D – Ageo – Aatm – Agf – Abar – Amisc

These factors are discussed in detail below.

The Sound Power Level (LWA) defines the total acoustic power radiated by a noise source expressed in decibels (dB) per 1 pico Watt (pW). Source noise terms for the various noise sources that will be utilised during the Construction Phase have been obtained from published data detailed within British Standard 5228 (Ref. 10.7).

The directivity factor (D) allows for an adjustment to be made where the sound radiated in the direction of interest is higher than that for which the sound power level is specified. For the purposes of the assessment, which considers construction plant operating at ground level and vessels on water, no directivity factor is considered. Other Project Activities as part of the Pre-Commissioning and Operational Phases have a different directivity factor; however, these have not been modelled for reasons explained in the relevant sections.

The geometrical divergence (Ageo) accounts for spherical spreading of the noise from the source within free-field conditions. The construction plant and associated noise sources can be considered as point noise sources, given the distance of receptors from proposed works, and therefore the attenuation due to distance may be calculated from:

- \( A_{geo} = 20 \log (d) + 11 \); and
- Where \((d)\) is the distance from the source to the receptor.
The atmospheric absorption factor ($A_{atm}$) considers the attenuation offered by the atmosphere as a result of the conversion of sound to heat. The degree of attenuation is dependent on the relative humidity and temperature of the air through which the sound is travelling and is frequency dependent. Increasing attenuation occurs towards the higher frequencies of sound.

Modelling parameters have assumed an ambient temperature of 10°C and 70% relative humidity which are found to result in worst case noise propagation. The annual average air temperature is 12.1°C, which fits well with the modelled parameters. The corresponding atmospheric attenuation factors are summarised below in Table 10.11.

The ground effect ($A_{gr}$) is the result of sound reflected by the ground interfering with the sound propagating directly from source to receiver, and the interaction of the sound with porous and absorptive ground cover. The prediction of ground effects depends on the source height, receiver height, propagation height between the source and receiver and the ground conditions.

The ground conditions are described according to a variable defined as $G$, which varies between 0 for 'hard' ground (includes paving, water, ice, concrete and any locations with low porosity) and 1 for 'soft' ground (includes ground covered by grass, trees or other vegetation). Predictions have been carried out using a receiver height of 1.5 m and an assumed ground factor ($G=0.8$). This ground factor corresponds to 20% of the ground being hard ground conditions between the source and receiver and represents a worst-case scenario. All areas where the sound is travelling over water are treated as being acoustically reflective ($G=0$).

The effect of any barrier or topographical obstruction ($A_{bar}$) between the noise source and the receiver position is that noise will be reduced according to the relative heights of the source, receiver and barrier and the frequency spectrum of the noise.

The predicted noise levels have been calculated using CADNA-A noise modelling software (Ref. 10.9), which implements the ISO 9613-2 prediction methodology. The predicted noise levels at receptors consider solely the noise from activities associated with the Project. Pre-existing ambient noise levels are not considered within the predictions, as the Russian regulations require that noise from South Stream activities achieves the absolute noise level criteria.

Noise levels have been calculated at the identified discrete receptor locations. Additionally, noise contour maps have been produced across the Wider Study Area at a height of 1.5 m above ground level.

Construction activity will vary in both intensity and location over time. Consequently, for the purposes of this noise impact assessment, eight different sub-phases within the Construction Phase were identified, focusing on stages where different activities overlap, some with pre-commissioning phases, and which likely represent peak activity levels for the Project.
Chapter 10 Noise and Vibration

10.12. It should be noted that this includes pre-commissioning activities during the later stages of the construction schedule.

Seven of these sub-phases relate to daytime construction activities and the eighth to night time construction activities. There are seven sub-phases that were used as the basis for different model simulations during the daytime period (Model References 1 - 7 in Table 10.12), which have been used to generate the set of noise contour plots. The different model simulations consider the peak activities that would occur throughout the Construction Phase. These, therefore, consider the worst-case noise impacts that may arise.

The scenarios have not considered the effects of offshore pipe-laying vessels. However, the scenarios 4 to 7 inclusive, incorporate the impacts associated with the dredging of the micro-tunnel exit pits. This is considered to be representative of the worst case offshore noise impacts associated with the construction of the Pipeline. This is as a result of the dredger being moored at the closest point to the shore, and assumed to be operating continuously, thereby having a great impact at onshore receptor locations. Noise sources terms for the dredger and gantry cranes on the pipe-laying vessels are broadly comparable. Therefore as pipe-laying vessels will be located at a greater distance offshore than the dredger, and will move further offshore as the construction of the Pipeline progresses, reduced noise levels at onshore receptor locations are anticipated to the levels predicted from dredging activities.

The noise impacts associated with the Varvarovka bypass access road have been modelled based on the vehicle flow data for each of the scenario time periods. The vehicle flow data comprises a majority of HGV traffic with a small percentage of light vehicles. For the purposes of the assessment it has been assumed that all vehicles predicted to use the Varvarovka bypass route are HGVs, which represents a worst case scenario. The noise impacts have been predicted assuming point noise sources travelling along the access road at the vehicular flow rates shown in Table 10.12. For the purposes of the assessment, it has also been assumed that vehicle speeds on the access road are 30 km/h, as a higher speed would not be representative of producing a worst case noise impact.

Night-time noise will result from tunnel boring activities and the operation of generator sets to supply power. The noise models run for the different time periods within the construction and pre-commissioning programme have been assessed in Model Reference 8. Table 10.12 details the noise models run for the different time periods within the construction and pre-commissioning programme. A further breakdown of the plant utilised for each source reference is given in Table 10.13.

Table 10.12 details the noise models run for the different time periods within the construction and pre-commissioning programme. The source references within Table 10.12 relate to the general activities undertaken. A further breakdown of the plant utilised for each source reference is given in Table 10.13.

To account for the shifting nature of work locations, various point source locations were used to aggregate the impacts of multiple noise sources, as detailed by the source reference number shown in Table 10.12. Point source locations were selected to represent the areas that would be expected to have the highest levels of activity and greatest number of noise sources.

Work to be undertaken in the nearshore section of the Project is included in the assessment. Activities considered include the dredging of the microtunnel exits. These activities are close to the shoreline and have the potential to impact on terrestrial receptors.

The details of the different plant items used for each source reference given in Table 10.12 are given below in Table 10.13. Source noise data have mainly been sourced from British Standard 5228-1 (Ref. 10.7), which provides sound level data ($L_{Aeq}$), maximum ($L_{Amax}$), and octave band data for a wide range of construction machinery. Each of the model simulations utilised this equipment data to predict construction noise level contours, as well as to predict noise levels at the closest sensitive receptors. All the simulations assumed a worst case scenario in which all equipment was operating simultaneously.

It is also necessary to consider the $L_{A_{\text{max}}}$ noise levels from construction operations, with regard to the criteria defined within the Russian Standard (Ref. 10.4).

Therefore, a review of available $L_{A_{\text{max}}}$ data has been undertaken from the published data contained within British Standard 5228. Data have been identified for specific items of plant where data exists for both the $L_{A_{\text{eq}}}$ and $L_{A_{\text{max}}}$ noise levels. The corresponding $L_{A_{\text{max}}}$ levels have been compared with the $L_{A_{\text{eq}}}$ levels to identify how much higher they are. A summary of the
plant identified, the corresponding noise levels, and noise level difference are given below in Table 10.15.

The analysis of typical construction plant noise levels indicates that typically the $L_{Amax}$ noise levels range from 5 to 9 dB(A) above the corresponding $L_{Aeq}$ noise level. Therefore, in order to assess the typical $L_{Amax}$ noise levels that may arise from construction activities, it is assumed that $L_{Amax}$ noise levels are 10 dB(A) above the predicted $L_{Aeq}$ noise levels at all receptor locations.

### 10.6.2 Assessment of Potential Impacts: Construction and Pre-Commissioning Phase

#### 10.6.2.1 Introduction

This section of the chapter assesses the noise and vibration impacts arising during the Construction and Pre-Commissioning Phase in the nearshore and landfall sections of the Project.

#### 10.6.2.2 Assessment of Potential Impacts (pre-mitigation)

**Pipeline and Landfall Construction and Pre-Commissioning Activities**

The noise emissions from activities associated with traffic on existing roads and port operations are treated separately.

The following noise generating activities have been identified:

- Onshore construction activities (e.g. noise emissions associated with the operation of construction vehicles, plant and equipment);
- Microtunnelling activities (e.g. noise emissions associated with the operation of construction vehicles, plant and equipment); and
- Pre-commissioning activities (e.g. noise emissions associated with operation of pumps used during hydro-testing, and boost compressors).
The assessment of noise impacts on human receptors resulting from these activities is discussed below. Only human receptors in the vicinity of the landfall area have been included in this assessment.

The predicted daytime noise levels for Model References 1 to 7, inclusive, are presented below in Table 10.16 to Table 10.22 respectively.

The predicted night time noise levels from Model Reference 8 are presented below in Table 10.23. The tables also provide the Impact Magnitude, based on the criteria in Table 10.8, developed from the Russian Standard (Ref. 10.4).

It should be noted that Model Reference 8 considers the impacts associated with the operations that will be undertaken 24 hour per day. These have been assessed with regard to the night time noise level criteria only. Achieving the night time noise level limit, which is 10 dB below the daytime limit, will ensure that noise from these sources will make a negligible contribution to cumulative construction and pre-commissioning daytime noise levels.

Note - The predicted noise levels for receptors of low sensitivity (Receptor 5 – unoccupied residential property) and ecological receptors (Receptors 9, 10, 11, and 12) are presented within the greyed out cells. The impact magnitude for Receptor 5 within the table is based on the property being occupied during construction works and hence having a high sensitivity – although it is not expected that this will occur. Predicted noise levels above the criteria are shown in bold italics.

Note: The predicted noise levels for receptors of low sensitivity (Receptor 5 – unoccupied residential property) and ecological receptors (Receptors 9, 10, 11, and 12) are presented within the greyed out cells. The impact magnitude for Receptor 5 within the table is based on the property being occupied during construction works and hence having a high sensitivity – although it is not expected that this will occur. Predicted noise levels above the criteria are shown in bold italics. The predicted noise levels from daytime construction operations are shown graphically within Figures 10.3 to 10.9 for Model References 1 to 7, inclusive. The 55 dB L<sub>Aeq</sub> noise level contour is shown in red on the figures relative to the identified receptor locations.

The predicted daytime noise impacts from Models References 1 to 7, inclusive, are given in Figure 10.3 to Figure 10.9, respectively, which indicates the location of the 55 dB L<sub>Aeq</sub> noise contour.

46369082
The night-time noise levels are shown graphically within Figure 10.10 for Model Reference 8. This figure indicates the location of the 45 dB LAeq noise contour which is the applicable night-time noise limit. It should be noted that the plant will operate during both the day and night time period. However, as the night time noise limit is more stringent than the daytime the noise impacts have therefore been assessed the night time criterion (45 dB LAeq) in both Table 10.23 and Figure 10.10.

As mentioned previously, the noise levels at the ecological receptors (receptors 9 to 12) have been calculated for use in Chapter 11 Terrestrial Ecology. Only the predicted noise levels at these receptors have been presented and no assessment of impact significance is included within this chapter.

A summary of the predicted impact significance for the construction noise Model References 1 to 8, inclusive, is given below in Table 10.24. This summary utilised the impact significance matrix provided in Chapter 3 Impact Assessment Methodology employing the predicted magnitude of the impact (Table 10.16 to Table 10.23) in combination with the sensitivity of the receptor (Table 10.6).

For the daytime period for the majority of the existing receptors, currently identified as occupied sites in proximity to the construction activities, sensitivity is high and the impact magnitude is negligible; therefore, according to the impacts significance matrix, the overall impact is Not Significant.

However, during Scenario 3 the impacts at Receptor 4, representative of a cluster of residential dwellings on the north-eastern part of Varvarovka, are moderate. As these receptors have a high sensitivity, the impact significance is High.

At Receptor 5, which is a new-build proposed residential building that is unlikely to be occupied during the Construction Phase, the sensitivity is negligible and the impact magnitude is, at worst, low; therefore the overall impact significance is Not Significant. Table 10.24 assumes that receptor location 5 is uninhabited during the Construction Phase.

The predicted noise levels have the potential to create greater impacts should Receptor 5 support human occupants during the Construction Phase. If this were to happen, the sensitivity would be high and the worst case impact magnitude would occur during the night-time period and is classified as low; therefore, the overall impact significance would be Moderate, as based on the overall broadband noise level (L_Aeq).

Figure 10.10
The Russian regulations also require an assessment of the spectral noise levels at the receivers. If it is assumed that Receptor 5 is occupied during the Construction Phase it can be seen from Table 10.17 (Scenario 2) that the noise level within the 1 KHz octave band may exceed the limit by 1 dB(A). The noise levels during the night time also exceed the 1 kHz and 2 kHz octave band levels by 2 dB(A) and 1 dB(A). The sensitivity of Receptor 5 (if occupied) is high and the impact magnitude is moderate; therefore, the overall impact significance would be **High**.

The predicted noise impacts during the night time period (Scenario 8), which indicate the cumulative noise impacts from micro-tunnelling and pre-commissioning using the booster compressor spread, indicate a high impact magnitude at the majority of receptors. As the receptors have a high sensitivity, the impact significance is **High**, for the majority of receptor locations. It should be noted that the significant noise source during this scenario is the booster compressors. Noise impacts arising from the micro-tunnelling plant, when considered in isolation, are **Not Significant**.

**Construction Vibration Impact Significance**

There are several sources of ground borne vibration anticipated during construction activities or from plant and equipment to be used (**Chapter 5 Project Description**).

At the microtunnel construction site, secant wall piling will involve the use of continuous flight augers, which give rise to levels of ground borne vibration that would be imperceptible beyond approximately 30 m (Ref. 10.7). Microtunnelling will be undertaken using a remotely controlled tunnel boring machine (TBM). The microtunnels will extend through soft to hard clay (<10 m) and loose to dense clayey gravel over predominantly marlstone, which has subordinate layering of sandstone, limestone and siltstone. When considering the worst case levels of ground borne vibration from the operation of the TBM (e.g. when encountering rock formations) the resulting levels of vibration would be imperceptible to human receptors at a distance of 100 m from the cutting face.

The proposed Pipeline corridors will employ a cut and fill method. Heavy plant associated with such operations will not give rise to high levels of ground borne vibration. Typically, the levels of ground borne vibration from a bulldozer are imperceptible to humans at a distance of approximately 20 m.

As the closest human receptors to the majority of construction works are at a distance of approximately 920 m (430 m for Receptor 5, if occupied) then the resulting levels of ground borne vibration will be imperceptible to occupants.

Note: The impact significance table assumes that Receptor 5 will not be occupied during the Construction Phase.
The Varvarovka bypass road is not anticipated to generate any significant level of ground borne vibration during construction as dynamic compaction, vibro compaction or piling techniques are not proposed to be used. The construction of a new level road surface, which will be adequately maintained, will ensure that ground borne vibration from vehicle movements will be negligible.

The booster compressors utilised during the pre-decommissioning stage are not anticipated to give rise to significant levels of ground borne vibration, as modern reciprocating engines are well balanced. Typically ground borne vibration would be imperceptible within tens of metres from such engines. Whilst there may be cumulative increases in the ground borne vibration where 80 such units are employed, given that the closest sensitive receptor is at a distance of approximately 1 km, it can be concluded that any ground borne vibration impacts will be negligible.

The existing residential receptors, cemetery and places of worship sensitivity classifications are high and the impact magnitude is negligible; therefore, the overall impact significance is **Not Significant**.

The impact of ground borne vibration on ecological receptors is not considered within this chapter, but is considered in **Chapter 11 Terrestrial Ecology**.

**Construction Traffic**

The impact of construction traffic is determined by assessing changes in road traffic noise levels due to the incidence of construction vehicles. The proposed construction traffic route will pass from the M25 through Rassvet, bypass Gai Kodzor and then onto the access road. The only other vehicles accessing the site will travel via the Anapa-Varvarovka road. The proposed transport routes are shown in **Chapter 5 Project Description**.

Data on the road traffic flows on the proposed transport routes have been gathered, the results of which have been presented in Appendix 9.1: Traffic and Transport Study. This includes figures showing the road links at which the traffic flow was counted. These locations were as follows:

- **Link 1** – Varvarovka, southern end of settlement, south of junction with access road;
- **Link 2** – Varvarovka, southern end of settlement, north of junction with access road;
- **Link 3** – North of Varvarovka, south of junction of Anapa to Sukko road and road from Gai Kodzor;
- **Link 4** – North of Varvarovka, east of junction of Anapa to Sukko road and road from Gai Kodzor;
- **Link 5** – Supsekh, western edge of settlement on Anapa to Sukko road;
- **Link 6** – Gai Kodzor, south of junction of temporary construction bypass and road from Rassvet;
- **Link 7** – Gai Kodzor, north of junction of temporary construction bypass and road from Rassvet;
Chapter 10 Noise and Vibration

- Link 8 – Gai Kodzor, east of junction of temporary construction bypass and road from Rassvet;
- Link 9 – Rassvet, south of junction of M25 and road to Gai Kodzor;
- Link 10 – Rassvet, east of junction of M25 and road to Gai Kodzor; and
- Link 11 – Rassvet, west of junction of M25 and road to Gai Kodzor southbound.

The total construction traffic proposed for the Project comprises a maximum of 531 HGV and 27 light vehicle movements per day; this peak will last from August to November 2014. During June and July 2014, there will be 498 HGV and 14 light vehicle movements per day. The proportions of vehicles that will access the different roads around the site have been estimated in Appendix 9.1.

The absolute change in the noise levels that will be generated by the increase in road traffic flow at these locations has been predicted using the Calculation of Road Traffic Noise (Ref. 10.10). The absolute change in the noise level generated by the increased traffic flow resulting from construction traffic using the pre-existing routes is shown below in Table 10.25.

According to GIIP, it is generally accepted that a change of less than 3 dB in noise level is not perceptible to human subjects, and therefore the magnitude of the impact at Links 1 to 6 and 8...
to 11 will be negligible, and the magnitude of impact at Link 7 will be low. The sensitivity of the receptors in the vicinity of the Links is high; therefore, the significance of the noise impact is **Not Significant** at receptors neighbouring Links 1 to 6 and 8 to 11, and **Moderate** at receptors neighbouring Link 7.

**Port Activities**

At the time of writing, a decision had not been made on the port that will be used to receive equipment and material for the purposes of the onshore construction activities. As detailed in **Chapter 5 Project Description**, the port of Novorossiysk is a potential option.

The port selected will be an existing commercial port. Consequently, ship movements and the handling of material would be part of the existing noise climate. It is therefore considered that whichever port is selected for the delivery of equipment and materials, it would be operated within the existing confines of potential impacts on neighbouring receptors.

### 10.6.2.3 Mitigation and Monitoring

The impact significance has been assessed as being **Not Significant** for the majority of the Construction and Pre-Commissioning Phase, and therefore the implementation of mitigation measured are not required for the majority of phases.

The exceptions where greater impacts have been identified, whereby mitigation measures need to be considered, result from periods of higher road traffic volumes (daytime), and pre-commissioning using the booster compressor spread (night time).

The residential area around Receptor 4 during Scenario 3, when the greatest road traffic flows will be experienced on the Varvarovka bypass road, will require mitigation to be implemented.

An acoustic screen along the boundary of the properties and Varvarovka bypass road will be installed to mitigate the noise impact. Typically this can be constructed from a timber fence, wall or earth bund, or any combination of the two. For fencing, example design principles to ensure effective mitigation include two layers of staggered boards, giving a minimum superficial mass of 10 kg/m², and ensuring that no air gaps exist at the base of the structure. The specification will be determined based on the number of vehicle movements on the road along with consultation with the owners of adjacent properties. An indicative location of the screen along with the noise contour plot is shown in Figure 10.11.

The predicted noise levels at the closest premises to the Varvarovka bypass road are predicted to fall to below 50 dB(A) with the implementation of a 3 m high barrier.

The resulting impact magnitude, with mitigation, is negligible, the receptor sensitivity is high, and the impact significance is **Low**.

The impact significance of Pre-Commissioning has indicated that during the cleaning, gauging and drying of the Pipeline between the Russian and Bulgarian landfall facilities (i.e. booster compressor spread operations) there is the potential for **High** impact significance to occur, and as such, mitigation measures need to be considered.
In order to reduce these noise levels by up to approximately 24 dB(A), it is expected that a combination of measures will need to be employed. These include the selection of inherently quiet plant with far lower sound power levels than used in the assessment; careful siting and orientation of the plant to minimise noise emissions at receptor locations; and the use of acoustic berms / barriers close to the pre-commissioning compound.

However, the degree of mitigation cannot be provided at this point in time, as the extent of mitigation will be dependent upon how great a reduction in noise levels can be achieved by the use of inherently quiet plant.

The predicted noise and vibration effects from the landfall and nearshore pre-commissioning cleaning and drying works have indicated that no mitigation measures need to be considered. In addition to the above it is considered that the Project will adhere to GIIP in order to reduce the impact of construction noise and vibration upon all receptors. Mitigation measures will be documented within the Project Environmental and Social Management Plan (ESMP) (Chapter 22 Environmental and Social Management), and are described below:

- Equipment will be throttled to a minimum or switched off when not in use;
- Internal access roads will be kept well-maintained to minimise noise impacts generated by vehicles dealing with difficult terrain;
- Drop heights of materials will be minimised which will reduce the noise levels generated by the collision of materials with the ground or other materials;
- As far as reasonably practicable, sources of significant noise will be enclosed;
- Plant and equipment will be used and maintained regularly in accordance with manufacturers’ instructions;
- Where possible, equipment and loading and unloading activities will be located away from noise-sensitive areas; and
- In consideration of the potential impacts arising from several noisy activities occurring at the same time, activities will be scheduled, where possible, to minimise overall noise levels.

Mitigation measures may need to be employed to reduce noise at Receptor 5 to acceptable levels; however, this is only in the event that this location is developed and occupied by residents during the Construction Phase. If this does occur, then consideration would be given to the following suitable measures:

- Selection of plant that gives rise to the lowest feasible noise emissions;
- Careful on-site location and orientation of plant; and
- The use of temporary soil screening bunds to reduce noise levels.

Figure 10.11
Details of the compliance noise and vibration monitoring that will be undertaken are included in the overarching Environmental and Social Monitoring Programme (Chapter 22 Environmental and Social Management).

The document collates the assessments undertaken for both this ESIA Report and the in-country EIA Report, and the monitoring commitments made in each.

The in-country monitoring requirements are based on fixed timescales for sampling and do not provide flexibility to capture the start of specific activities. In addition, the in-country requirements for noise monitoring are based on both receptor locations, and points that are not representative of sensitive receptors.

Therefore, the monitoring programme has collated the commitments from both the ESIA Report and the EIA Report into a single working document that fulfils the requirements of both.

The committed monitoring regime goes beyond the in-country requirements in terms of both monitoring location numbers and frequency of monitoring.

This has been undertaken in order to capture the range of activities being undertaken, and a risk based approach has been adopted in order to target compliance noise monitoring at the starting time when specific activities which have the potential to exceed the noise limits occur.

With regard to the construction activities monitoring has been specified to occur at the start of the following activities:

- Daytime construction traffic during period of maximum movements (mid-June to November 2014);
- Daytime trenching, pipe fabrication, pipe laying and landfall facilities construction; and
- Night-time microtunnelling works.

Further to the above the assessment of the Pre-Commissioning Phase noise levels has highlighted that cleaning, gauging and drying of the pipelines between the Russian and Bulgarian landfall facilities is likely to be a key stage when compliance monitoring will be required. Given that this plant will operate on a 24 / 7 basis, and that the night time noise criteria is more stringent, compliance monitoring during the night time period will need to be scheduled during the first night of such plant operations. Compliance noise monitoring would be undertaken at the closest receptor locations to the pre-commissioning plant. Demonstrating compliance with the noise criteria at the closest receptors would ensure compliance with the criteria at all receptor locations.

10.6.2.4 Residual Impacts: Construction and Pre-Commissioning

The residual impact significance of both noise and ground borne vibration at sensitive receptors during the Construction and Pre-Commissioning Phases is summarised in Table 10.26.

For the majority of impacts are predicted to be Not Significant with the exception of two sub-phase scenarios.
During periods of the highest traffic flows there is predicted to be an impact on the boundary of the Low impact significance following the inclusion of a noise barrier to mitigate noise levels.

The activities associated with the use of the compressor booster spread for the cleaning, gauging and drying of the pipelines between the Russian and Bulgarian landfall facilities during Pre-Commissioning, which will result in an estimated Low impact significance at neighbouring receptors. It should be noted that the degree of mitigation feasible cannot be directly quantified at this point in time.

10.6.3 Assessment of Potential Impacts: Operational Phase

10.6.3.1 Introduction

The activities associated with the Operational Phase of the Project are:

- Operation of the pipeline inspection gauge (PIG) launching facility on an infrequent basis;
- Occasional vehicle movements and associated routine maintenance activities;
- Gas flow within the Pipeline; and
- Venting of gas from the landfall facilities during a shut down for maintenance or repairs.

10.6.3.2 Assessment of Potential Impacts (pre-mitigation)

The operation of the PIG launching facility will not involve any significant noise generating plant or machinery. The closest residential receptor is at a distance of over 1 km from the facility. As receptor sensitivity is high and the impact magnitude is negligible, the resulting noise impact significance is Not Significant.

Noise impacts resulting from infrequent routine maintenance and associated vehicle movements to the facility are considered to be of negligible magnitude given the large distances to the nearest noise sensitive receptors. As receptor sensitivity is high and the impact magnitude is negligible, the resulting noise impact significance is Not Significant.

Gas flow within the Pipeline has the potential to generate relatively low levels of sound. However, as the Pipeline will be buried below a minimum of 1.5 m of backfill, the resulting sound levels above ground level are anticipated to be inaudible. The resulting noise impact at sensitive residential receptors at considerable distance from the Pipeline corridor is therefore considered to be of negligible impact magnitude. As receptor sensitivity is high and the impact magnitude is negligible, the resulting noise impact significance is Not Significant.

*Note – if Receptor 5 is constructed and becomes occupied during the Construction Phase, mitigation measures may need to be implemented.  

*Complete.*
The impact of operational noise on ecological receptors is addressed within Chapter 11 Terrestrial Ecology.

The landfall facility will house a vent stack for the venting of gas from the pipelines during maintenance activities. The venting of gas from the Pipeline has the potential to generate jet noise. The resulting noise that may be generated has therefore been assessed using the procedures for estimating gas jet noise given within Engineering Noise Control (Ref. 10.11). The resulting overall acoustic power is determined to be $5.7 \times 10^{-9}$ Watts, which equates to a sound power level ($L_w$) of 37.6 dB. The sound power level is further corrected to account for the directivity of the noise and the number of the pipes within the stack (eight), each of which will vent to atmosphere.

The predicted impact magnitude at all receptor locations is shown to be negligible. Though the sensitivity is high the resulting impact significance at all receptors is Not Significant.

10.6.3.3 Mitigation and Monitoring

No mitigation of noise or vibration from the Operational Phase is required.

The compliance noise and vibration monitoring is detailed in the overarching Environmental and Social Monitoring Programme (Chapter 22 Environmental and Social Management).

The document collates the assessments undertaken for both this ESIA Report and the in-country EIA Report, and the monitoring commitments made in each.

The Russian National EIA Report has committed to undertaking noise monitoring once per year during the Operational Phase.

Given that this ESIA Report has not identified any significant noise impacts, and no requirement for mitigation during the Operational Phase, it is concluded that noise monitoring at a greater frequency that the in-country commitment is not required.

10.6.3.4 Residual Impacts: Operational Phase

The noise and vibration impacts associated with the Operational Phase are not anticipated to require any form of mitigation. The resulting impact magnitudes for both noise and vibration are considered to be negligible, and noise and vibration levels are expected to be compliant with Russian Regulations; as the receptor sensitivity is high, the resulting impact significance is Not Significant, as summarised in Table 10.27.

10.6.4 Assessment of Potential Impacts: Decommissioning Phase

10.6.4.1 Introduction

A decommissioning programme will be developed during the Operational Phase. The South Stream Pipeline System has a design life of 50 years, although this may be extended subject to close monitoring.

The decommissioning of onshore facilities has the potential to result in noise impacts at sensitive receptor locations, including human and ecological receptors. Offshore decommissioning of the Pipeline is considered to be at suitably large distances from terrestrial receptors and, therefore, there would be no impact.

10.6.4.2 Assessment of Potential Impacts (pre-mitigation)

The anticipated onshore noise and vibration impacts are expected to arise from the following activities;

- The demolition of facilities and infrastructure;
- Equipment and vehicle movements; and
- Earthworks.

The intensity and duration of works associated with the Decommissioning Phase are expected to be no greater than the Construction Phase. Given that the noise and vibration impacts associated with the non-construction traffic related activities, and excluding pre-commissioning activities which would not be undertaken, have been shown to be Not Significant for human receptors, it is considered that decommissioning activities would be likely to give rise to similar insignificant impacts, subject to no further residential buildings being built closer to the Pipeline over the course of the Operational Phase, and selection of appropriate routes for traffic away from habitable areas.

However, it is likely that Receptor 5 would be occupied during the Decommissioning Phase of the Project. As this receptor is located closer to the Pipeline corridor, there is the potential for elevated noise levels at this location during decommissioning. If noise levels equivalent to those generated during construction are received at this location, the impact at Receptor 5 could be of High significance, prior to the implementation of mitigation measures.

Given that the Decommissioning Phase will be undertaken a considerable time in the future, a re-appraisal of the following would be undertaken:

- A review of prevailing international and national legislation, regulations and GIIP;
- An assessment of new receptors that may have been introduced into the immediate vicinity; and
- An assessment of potential noise and vibration impacts once a detailed methodology and programme has been developed for the Decommissioning Phase.
Assessments will be undertaken during the Operational Phase to confirm that the planned decommissioning activities are the most appropriate to the prevailing circumstances and proposed future land use.

**10.6.4.3 Mitigation and Monitoring**

The requirements for mitigation and monitoring will be identified as part of the assessment to decommission the Project. As noise levels equivalent to those generated during the Construction Phase are expected, and that Receptor 5 is occupied, it is considered that by careful selection and orientation of plant, combined with the implementation of noise barriers, it is feasible to reduce noise impact from High to Low significance.

**10.6.4.4 Residual Impacts: Decommissioning Phase**

It is anticipated that the resulting impacts from decommissioning are likely to be of Low impact significance. However, this will be assessed in full as part of once a decommissioning methodology has been developed.

**10.7 Unplanned Events**

There are no significant sources of noise that will occur in the event of an unplanned event. Hence the significance of the impact of the noise generated by unplanned events will be Not Significant. Further details on unplanned events relevant to the Project are detailed in Chapter 19 Unplanned Events.

**10.8 Cumulative Impact Assessment**

The cumulative impacts associated with the Project relating to noise and vibration are assessed in Chapter 20 Cumulative Impact Assessment.

10.9 Conclusions

An assessment of the worst case noise and vibration impacts associated with construction and pre-commissioning has been undertaken. The results predict that the majority of noise and vibration impacts will be **Not Significant** at existing sensitive receptors neighbouring the Project, with a number of exceptions.

At Receptor 4 a **High** impact is predicted. The Receptor 4 location is mainly affected by road traffic noise using the Varvarovka bypass road, and the **High** impact significance is only predicted to occur during periods when the greatest vehicle movements will occur. Mitigation in the way of a noise barrier is proposed along the boundary of the Varvarovka bypass road. Post mitigation noise impacts are predicted to be of **Low** impact significance.

The pre-commissioning stage that utilises the booster compressor plant is predicted to give rise to a **High** impact at the majority of neighbouring receptors. By selection of inherently quiet plant, careful siting, and the use of acoustic bunds / barriers it is potentially feasible to reduce noise impacts to **Low** significance. This would however, be dependent on being able to source inherently quieter plant than the type used in the assessment. Vibration impacts are classified as being **Not Significant**.

The assessment at a proposed residential site (Receptor 5) has indicated that the impact significance at this location is also considered to be **Not Significant/Low** during all construction and pre-commissioning scenarios considered. This is based upon the receptor having a negligible sensitivity through the Construction and Pre-Commissioning phases, as the development is not anticipated to be complete for occupation during this period.

The assessment of the Operational Phase has also concluded that noise and vibration impacts will be **Not Significant**.

The assessment of decommissioning activities will be undertaken during the Operations Phase of the Project. However, it is anticipated that decommissioning works can be suitably mitigated so that the majority of impacts are considered likely to be **Not Significant to Low** significance. An assessment of potential impacts will be undertaken prior to decommissioning.

11 Terrestrial Ecology

11.1 Introduction

This chapter presents an assessment of the potential impacts of the Project on terrestrial ecology. The assessment has identified sensitive ecology receptors within the Project’s zone of influence and considered the potential for these receptors to be impacted upon by the Project activities. The assessment follows the recommendations and requirements of the International Finance Corporation (IFC) Performance Standards 6 (PS6): Biodiversity Conservation and Sustainable Management of Living Natural Resources and other applicable standards (see Section 11.6.5).

In order to assess potential impacts, this chapter provides a description of the approach to the study. The scoping process is detailed, during which receptors were identified through an analysis of survey data, and a review of local, national and international requirements and standards. This chapter describes the spatial and temporal boundaries used in the assessment, the baseline conditions within these areas, the assessment methodology, the mitigation measures required to avoid or minimise any significant adverse effects, and the likely residual effects after these measures have been implemented. The relevant stakeholder consultation activities on-going and undertaken for the Project are also documented. The potential for cumulative impacts with other projects in the surrounding area is addressed in Chapter 20 Cumulative Impact Assessment.

This Project adheres to the ‘mitigation hierarchy’ as defined in IFC PS6, i.e. impacts should be progressively avoided, minimised, restored or offset if necessary, with priority given to the actions which are earliest in the hierarchy. Therefore, the Project will seek to avoid impacts on biodiversity. When avoidance of impacts is not possible, measures to minimise impacts and to restore biodiversity will be implemented. Offsetting is only considered if these measures do not result in a reasonable expectation of no net loss of biodiversity (or a net gain in respect of critical habitats). Given the complexity in predicting project impacts on biodiversity over the long term, the Project will adopt a practice of adaptive management in which the implementation of mitigation and management measures are responsive to changing conditions and the results of monitoring, until the necessary management objectives have been achieved.

11.2 Scoping

The terrestrial ecology impact assessment for the Project was defined through a scoping process, which identified ecological receptors and potentially significant impacts related to the Project. An important component of the scoping process was the definition of existing baseline conditions (i.e. the prevailing ecological characteristics against which the potential impacts of the Project could be assessed). Baseline conditions were identified primarily through the review of ecological information available from studies undertaken for the Project, including extensive feasibility, engineering and environmental surveys carried out in 2011, 2012 and 2013 (detailed in Section 11.4.4). Key steps in the scoping process for terrestrial ecology comprised the following:
Chapter 11 Terrestrial Ecology

- The Project design was reviewed to identify activities with a potential to significantly affect ecological receptors;
- Ecological receptors within the Project’s likely area of influence (see Section 11.3 for definition) were identified through a review of secondary data (see Section 11.4.2 for further detail), primary data (detailed in Section 11.4.4), and professional expertise;
- A gap analysis of the available information to identify shortfalls of ecological knowledge that would need to be addressed within the ESIA and in particular those that required additional ecological field surveys;
- Identified Project activities and receptors were examined through an Environmental Issues Identification (ENVIID) process (described in this section below);
- A review of relevant national and international legislative requirements and international standards and guidelines to ensure legislative and policy compliance (relevant requirements are detailed in Section 11.6.5 Applicable Standards and Chapter 2 Policy, Legislation and Administrative Framework); and
- Stakeholder consultation activities, including consultation meetings held after the scoping report was disclosed (detailed below).

11.2.1 ENVIID

An ENVIID was undertaken to assist in the identification of environmental and social issues and receptors, including those relevant to the terrestrial ecology (the ENVIID process is further described in Chapter 3 Impact Assessment Methodology). During the ENVIID process, each activity was examined, drawing upon the experience of the technical specialists and their understanding of the extent and nature of the Project activities and the natural environment, to understand:

- How activities were expected to interact with ecology receptors, and whether this would result in a positive or negative impact; and
- Which receptors would potentially be impacted by each activity and the potential significance of that impact.

The outcome of the ENVIID was a register which identified the various elements of the Project and their interaction or potential impact on sensitive ecological receptors.

11.2.2 Stakeholder Engagement

A number of stakeholder consultation activities were undertaken during the scoping phase (details can be found in Chapter 6 Stakeholder Engagement). The key issues that were raised by stakeholders related to the reinstatement of the cliff area to the west of the Study Area and general protection of the natural environment. Details of the issues raised relevant to this chapter are detailed in Table 11.1.

Chapter 11 Terrestrial Ecology

11.2.3 Analysis of Alternatives

An important part of the ESIA process was the analysis of alternatives (see Chapter 4 Analysis of Alternatives for more detail). In the course of considering Project design alternatives, technical decisions were taken that resulted in avoidance of some potential impacts completely.

A comparative ecological analysis of the two alternative routes (reasoning for the two routes can be found in Chapter 4 Analysis of Alternatives) was conducted by Gazprom in 2010 (Ref. 11.1); reference is also made in Appendix 20.1. That study showed that the location of the Russkaya compressor station (CS) had fewer environmental impacts compared to the alternative Beregovaya location. Undertaking the Project at the Beregovaya location in close proximity to the existing compressor station of the Blue Stream Pipeline Compressor Station would have resulted in unacceptable cumulative impacts associated with the contemporaneous operation of the Blue Stream Pipeline Compressor Station and the compressor station required for the Project. On this basis, the Russkaya CS site was selected, resulting in the Anapa landfall location being selected.

11.3 Spatial and Temporal Boundaries

11.3.1 Spatial Boundaries

11.3.1.1 Landfall Section

A detailed description of the landfall, nearshore and offshore sections of the Project Area is provided in Chapter 5 Project Description; the landfall, nearshore and offshore sections are

Complete.
defined primarily in relation to the different construction activities employed in each, and are not defined in ecological terms.

The landfall section, including the landfall facilities\textsuperscript{1}, is approximately 4 km in length. In this section, the pipelines extend from the tie-in approximately 100 m upstream of the landfall facilities, in a south-westerly direction to four microtunnel entry shafts approximately 2.4 km from the landfall facilities. The pipelines will enter the microtunnels and continue in a south-westerly direction for approximately 1.4 km, to emerge from the seabed approximately 400 m offshore. According to this technical definition, the landfall section includes approximately 400 m of marine environment, which is not a focus of this chapter. (Marine receptors within the nearshore and offshore sections (including sea birds) are addressed within \textbf{Chapter 12 Marine Ecology}). Upstream and downstream of the landfall facilities, the four pipelines will be installed using open-cut construction techniques.

\textbf{Study Area and Wider Study Area}

When defining study areas for terrestrial ecology, various elements of the Project were reviewed. Within the landfall section these included:

\begin{itemize}
  \item The four pipelines that will be installed using open-cut construction techniques;
  \item Access roads and junction(s) for access of operations vehicles from existing roads to the Right of Way (RoW);
  \item The landfall facilities; and
  \item Microtunnel onshore entry shafts and section of microtunnelling extending as far as the shoreline.
\end{itemize}

A Wider Study Area was defined as 15 km around the centrepoint of these elements (although only extending up to the coastline, see Figure 11.1). Contextual information on the occurrence of protected or designated sites and threatened species in this area was reviewed.

The Study Area was more focused than the Wider Study Area, and covered an area of approximately 1 km surrounding the landfall section, extending to the coastline. Where access roads were located outside of this 1 km buffer, the Study Area was extended to 50 m either side of the proposed alignment (see Figure 11.2). The Study Area was subject to field survey in 2011, 2012, and 2013 (see Section 11.4).

\begin{footnotesize}
\footnotesize
\footnotesize
\textsuperscript{1} The landfall facility (approximately 4.85 ha in area) will include of metrology equipment, PIG traps, ESD valves, block and other valves, gas heating system, electrical instrumentation and other equipment; see Chapter 5 for further details.

- Permanent access road to be constructed by Gazprom Invest
11.3.2 Temporal Boundaries

The assessment includes the four phases of the Project:

- Design and Development;
- Construction and Pre-Commissioning (the duration of which is approximately 18 months);
- Operational including Commissioning (an approximately 50 year period); and
- Decommissioning.

Therefore, the temporal boundary for the assessment is the end of the Decommissioning Phase, including associated demolition, removal of infrastructure and restoration works.

11.4 Baseline Data

11.4.1 Introduction

An extensive literature review and consultation with statutory bodies, interested parties and universities (see Sections 11.4.2 and 11.4.3) provided contextual information on potential terrestrial ecology receptors (habitats and species) within the Wider Study Area, and on their ecology, distribution, and pertaining threats. This information provided the contextual base upon which further field surveys were planned (see Section 11.4.4).

11.4.2 Secondary Data

11.4.2.1 International, National and Regional Assessments of Extinction Risk

In order to identify the potential presence of plant and animal species of conservation importance within the Study Areas, international, national and regional assessments of extinction risk were consulted. These included:

- The RDB of the Russian Federation (RF) for plants (Ref. 11.2) and for animals (Ref. 11.3);
- The Red Data Book (RDB) of the Krasnodar Krai (KK) for plants (Ref. 11.4) and for animals (Ref. 11.5); and
- The International Union for Conservation of Nature (IUCN) Red List of Threatened Species (RL) (Ref. 11.6).

---

2 Secondary data refer to existing information that was not collected for the purpose of the Project; e.g. published literature, or reports / information held by government and non-governmental organisations. Primary data refer to information that was collected specifically for the Project; e.g. ecological surveys described in Section 11.4.4.

These publications provide taxonomic, conservation status and distribution information for each listed species. Table 11.2 presents the classification system used by the IUCN RL, the RDB RF and the RDB KK for representing the extinction risk of species (Ref. 11.2, Ref. 11.3, Ref. 11.4, Ref. 11.5 and Ref. 11.6).

The IUCN considers species listed as VU and above to be species of particular conservation concern due to their high risk of extinction in the wild. Species classified as VU or above on the
IUCN Red List, or two and above on the RDB RF and RDB KK are referred to as ‘threatened’ in this chapter.

For ease of reference, all species which are listed on the IUCN RL, RDB RF and RDB KK are referred to in this chapter as ‘red list species’, or as species of conservation concern / importance.

Within the Russian Federation, species assessed as categories 1-3 by the RDB RF and RDB KK, are afforded protection under Russian legislation and are therefore ‘protected species’ (Ref. 11.7).

11.4.2.2 Consultation

Statutory Body Consultation

The Ministry of Natural Resources of Krasnodar Krai (MNRKK) was consulted in February 2013 to provide information on the presence of threatened flora and fauna, as well as protected areas, within the Wider Study Area. The MNRKK confirmed that the landfall section of the Project Area was outside of any designated site of regional or national importance. The MNRKK also confirmed that the RDB KK and RDB RF are the official documents which contain information on the status and distribution of threatened and protected species within the Krasnodar region.

The Ministry of Natural Resources and Environment (MNRE) of the Russian Federation was consulted in February 2013 to obtain information on the Utrish Specially Protected Natural Area (SPNA) and to enquire whether the MNRE were aware of previously conducted ecological studies within the Wider Study Area. The MNRE returned lists of RDB species supported by the Utrish SPNA and confirmed that it has no knowledge of previously conducted ecological surveys within the Wider Study Area.

Other Interest Groups

External Experts

A meeting was held with Semon Kustov, an invertebrate specialist from the Kuban State University on 11th September 2013. The purpose of the meeting was to discuss the potential presence of threatened invertebrate species included in the RDB RF and RDB KK. Mr Kustov was able to provide information on the known distribution and ecology of these species.

A meeting was held with Dr Olga Leontyeva from Moscow State University on the 31st July 2013. Dr Leontyeva is an ecologist with more than 20 years’ experience, and a recognised expert in the biology and ecology of Nikolski’s tortoise, *Testudo graeca nikolskii*. The discussion with Dr Leontyeva addressed the species’ population status within the Study Area, habitat requirements and biology. Taking into consideration existing data, the need for and scope of an additional population size class survey was discussed, and planned for October 2013. Dr Leontyeva also advised on a mitigation strategy in relation to Project activities proposed at the time.
Utrish Nature Reserve

An initial meeting was held in Anapa with Dr Alexandr Grigorievich Krokhmal, Director of State Nature Reserve “Utrish” on 18th April 2013. The purpose of the meeting was to understand the purpose, objectives and focus of the Utrish, which the Director explained. Potential cooperation during Construction and Operational Phase of the Project - in particular, mitigation measures for the Red Data Book species – were briefly discussed. Dr Krokhmal stated that, on the basis of information available to him, he had no concerns about the Project. A subsequent visit to the territory of the reserve was conducted on 1st June 2013 to contextualise information received from the Director.

A further meeting was held with Dr Krokhmal on 12th September 2013 to discuss potential involvement of the Utrish SPNA in providing mitigation options for Nikolski’s tortoise.

11.4.3 Data Gaps

A review of secondary data provided information on the likely presence of habitats and species within the Wider Study Area. However, secondary data alone were insufficient to accurately determine habitat type and quality, as well as species presence or absence within the Study Area. Field surveys (for primary data) were therefore undertaken to obtain this information, so that potential impacts could be assessed.

11.4.4 Primary Data / Baseline Surveys

11.4.4.1 Study Area

Introduction

Baseline surveys were undertaken in 2011, 2012, and 2013 to determine the presence of terrestrial ecology receptors within the Study Area. The field surveys have been used as the primary source for characterising the terrestrial ecology baseline. The approach and methods employed for these surveys are presented below.

The surveys completed in 2011 were limited to publically accessible areas across the entire Study Area (Figure 11.3). The surveys completed in 2012 focussed primarily on the Pipeline construction corridor (Figure 11.4). The surveys completed in 2013 focussed on the access route options (Figure 11.4).

Habitats and Flora

2011 Habitats and Flora Survey

Botanical surveys were undertaken between April and July 2011 to map broad habitat types within the Study Area in accordance within generally accepted survey methodology (Voronov, 1973, as cited in Ref. 11.9). Prior to the field survey, aerial photographs were reviewed to determine the location and extent of broad habitat areas or vegetation communities. These areas were then ground-truthed to confirm or to amend the findings of the aerial photography
review, as well as to gather information on the structure and composition of vegetation within the broadly identified habitat types.

Following the ground-truthing, a series of sample plots were prepared and surveyed within the Study Area (see Figure 11.3 for sample plot locations) with an exhaustive list of plant species recorded within each plot. Specimens requiring laboratory identification were stored and later examined. Species were identified with the use of local flora guides (Kosenko, 1970 and Zernov, 2002 as cited in Ref. 11.9); species of conservation concern were determined by reference to the RDB RF and RDB KK. Within each plot, abundance and projective cover were defined according to the Domin scale (Braun-Blanquet, 1965 as in Ref. 11.9). The location of each plot was recorded using a Global Positioning System (GPS) (Figure 11.3) and the plot and individual plant specimens photographed.

Surveys were undertaken at a suitable time of year for botanical survey (between April and July), when a wide range of both flowering forbs and grasses would have been visible for identification.

In addition, the freshwater habitat surveys were undertaken which included sampling both phytoplankton and zooplankton to contribute to the characterization of the waterbodies present (Ref. 11.9).

2012 Red List Flora Survey

Targeted botanical surveys were undertaken in August 2012. Surveyors focussed on recording species of conservation concern, along the proposed Pipeline construction corridor and within the landfall facilities footprint. Where encountered, red list species were recorded and mapped with the use of a GPS (see Figure 11.6). The location and extent of the area surveyed in 2012 is shown in Figure 11.4.

2013 Red List Flora Survey

Targeted botanical surveys were undertaken over a one-week period during June 2013. Surveyors focussed on recording red list species along the proposed access route options. Where encountered, red list plant species were recorded and mapped with the use of a GPS (see Figure 11.6). The location of the 2013 survey transects is depicted in Figure 11.4.

Fauna

Introduction

Extensive baseline surveys conducted for the Project in 2011 provided substantial primary data that informs this impact assessment. Surveys undertaken between April and July 2011 employed various methods to record and count animals present within the Study Area, including:

- Walked and driven transects surveys - employed to count amphibians, reptiles, birds, and larger mammals (Table 11.3);
- Traps and habitat cylinders - used to count smaller mammals such as rodents; and
Various aquatic sampling methods – employed to determine fish, phytoplankton and zooplankton presence and populations (Ref. 11.9).

Details of the 2011 faunal survey transects are summarised in Table 11.3, and depicted in Figure 11.3 and Figure 11.5. The following sections describe the surveys for faunal groups.

Invertebrates

2011 Surveys

Freshwater zoobenthos surveys were sampled in the two small watercourses within the Study Area. The zoobenthos were sampled, fixed in formalin and identified under a microscope using appropriate keys (e.g. Lipin, 1950, as cited in Ref. 11.9).

2012 Surveys

Invertebrate surveys were undertaken during 2012 and were largely restricted to a habitat suitability assessment, although where observed, species were recorded. Surveyors focussed on assessing the suitability of habitat along the Pipeline and landfall facilities construction footprint (excluding the micro-tunnel area) to support red list invertebrates.

Fish

Fish were sampled in 2011 in the two small watercourses within the Study Area in accordance with the best practice methods contained in Rass, Kazakova, 1966; Pravdin, 1966; Koblitskaya, 1981 (as cited in Ref. 11.9) and identified using field keys (Berg, 1948; Troiskiy and Tsunikova, 1988 as cited in Ref. 11.9). Presence or absence and where appropriate, population densities of fish were determined in accordance with these methods.

Herpetofauna

2011 Surveys

Transect surveys were employed to determine population densities of amphibian and reptile species within the Study Area. These were undertaken along transects 1, 2, 3, 5, and 6. Surveyors walked along each route with the aim of observing individual animals, as well as signs such as shed skins and droppings. Due to the relatively small size of herpetiles, the transect width was limited to two metres (one metre each side of the transect line). Where species were recorded, their location was noted with the use of a GPS. Surveys were timed to include early morning surveys, when reptile activity was likely to be at its highest. The population survey followed standard survey methodology for assessing herpetofauna populations, as is described in Novikov, 1953; Pesenko, 1982; and Scherbak, 1989 (as is cited in Ref. 11.9). This comprised the following:

- The peak count (highest number of individuals recorded on one survey across the entire survey effort) of each species was recorded per habitat type;
- The population density for each species was then calculated using a density formula which arrived at a number of species per 1 hectare (ha) (Chelintsev, 1996 as cited in Ref. 11.6); and

Relative abundance was also calculated based on the following scale of animal occurrence: 0 – species not encountered; 1 - species is rare; 2 – species inconsiderable in number; 3 – species is common; and 4 – species is numerous with many encounters on the majority of routes (Pestov,
During the transect surveys potential refuges encountered, such as wood or rock piles, were checked for sheltering individuals.

Additional specific surveys for amphibians were undertaken concurrently, which included the visual inspection of water bodies for both larvae and adults. Where water bodies were too deep or turbid for visual inspection, hand nets were used to capture animals. Potential amphibian spawning sites such as streams and ephemeral puddles were identified and mapped.

2012 Surveys

The proposed Pipeline and landfall facilities construction footprint was surveyed over six days in August 2012. The aim of the survey was to supplement the information collected during the 2011 surveys and target the proposed Pipeline construction corridor and within the landfall facilities footprint. Surveyors walked a series of transects through suitable reptile habitat with the aim of observing individuals or signs (e.g. shed skins, tracks etc.) (See Figure 11.6). In addition, surveyors conducted refugia searches, checking under fallen wood or boulders, to uncover sheltering reptiles. Care was taken to not harm or disturb any individuals where uncovered. Surveys were timed to include early morning and late afternoon surveys, when the probability of recording basking reptiles was greatest.

Amphibian surveys were undertaken concurrently with reptile surveys in 2012. Surveys involved direct observation and listening for (in the case of European tree frog *Hyla arborea schelkownikowi*) individual amphibians and their signs and refugia surveys. Areas most likely to support amphibians, including wet areas within the mesophilic forest and meadow and adjacent to streams, were targeted.

2013 Surveys

Route options for the temporary access roads were surveyed for reptiles and amphibians during June 2013. Surveyors walked a series of transects through suitable reptile habitat with the aim of observing individuals or signs (e.g. shed skins, tracks etc.) (Figure 11.4). In addition, surveyors conducted refugia searches, checking under fallen wood or boulders, to uncover sheltering reptiles. Care was taken to not harm or disturb any individuals where uncovered. Surveys were timed to include early morning and late afternoon surveys, when the probability of recording basking reptiles was greatest.

In addition to the access road survey, a targeted Nikolski’s tortoise *Testudo graeca nikolskii* survey was undertaken by Dr. Leontyeva from the 8th October to the 14th November 2013. This survey had the following primary objectives:

- To determine an approximate size class estimate for the Nikolski’s tortoise population within the Tortoise Survey Area (see Figure 11.5); and

---

3 The Tortoise Survey Area is a subset of the Study Area and was defined based on the location of the Project’s infrastructure and the known daily range of tortoise (approximately 300 m)
• To obtain information on the habitat preference and the likely distribution of the tortoise within the Study Area during its hibernation period.

The survey area covered the Pipeline footprint and associated access roads plus approximately 300 m buffer. The survey was completed by between three and five surveyors, walking transects through the Tortoise Survey Area. The total length of transects walked by the surveyors was 260 km. The visible survey width of the transects varied between four and six metres, depending on the density of the vegetation. This gives an approximate area surveyed of 130 ha (assuming an average of 5 m survey width). The location of all tortoises found during the survey was recorded using a GPS. Individual tortoises were marked with a temporary marker to avoid double counting during the survey. Furthermore, information including each individual’s sex, approximate age, and size was recorded, as well as a description of the habitat within which it was observed. Photographs of each individual were also taken.

As well as recording tortoises, incidental sightings of other herpetiles species were also noted during the survey.

Birds

2011 Surveys

During 2011, both transect and point count surveys were completed. Bird surveys were undertaken within the Study Area during six days between April and June 2011. During all surveys, information including the species, habitat and signs of breeding was recorded (Ref. 11.6).

Bird transect surveys were completed along routes 1-5 and 7, which totalled 18.5 km in length (see Figure 11.3 and Table 11.3). The surveys followed the borderless strip methodology described by Ravkin 1967 (as is cited in Ref 11.9). This method involved surveyors recording all birds which were heard or seen within each habitat type. Surveyors recorded the species, number of individuals, behaviour (e.g. nesting, feeding, and resting) and distance from the recorder. The census routes were representative of the habitats contained within the Study Area, with routes covering the following areas:

• Xerophilous shrub woodland (shiblyak) – 4.17 km;
• Mesophilic forest – 2 km;
• Juniper woodland and tomillyar – 3.18 km;
• Steppefied secondary meadow – 2.63 km;
• Mesophilic meadow – 0.8 km;
• Coastal shingle – 2.4 km; and
• Urban and agricultural habitats – 4.45 km.

Bird population densities were calculated according to Ravkin, 1967 (as cited in Ref. 11.9). This method calculates the density of birds encountered perched and flying separately.
Species composition within habitats with a complex structure, including the mesophilic and secondary steppefied meadow, juniper woodland and urban areas, was further investigated using point counts. Surveyors identified a typical stand of vegetation (or plot) within each habitat type subject to this survey method and recorded bird species and numbers within each plot. Surveying of each plot was repeated at each plot over the course of the three months (from April – June 2011).

2012 Surveys

During the August 2012 survey of the proposed Pipeline construction corridor and within the landfall facilities footprint, incidental sighting of birds were recorded. Information about the species, sex, age, behaviour, and habitat was recorded. The surveys included early mornings when birds are likely to be more active. A single dusk survey was also completed.

2013 Surveys

During the June 2013 survey of the access road options and landfall sites, a field ornithologist recorded all bird species observed. The following information was collected for each species recorded: sex, age, notes on behaviour and the habitat in which the species was observed. Population densities were not calculated. The surveys included early mornings when birds are likely to be more active.

Mammals

2011 Surveys

Mammal surveys were undertaken in 2011 within the Study Area, which employed both transect surveys and the use of traps (depending on the species). A summary of the methods employed for these surveys is provided below (Ref. 11.9).

Small rodents were surveyed using a trap-line methodology. This involved using baited traps arranged in a line of 25 traps, spaced 5 m apart. Fifty trapping days were undertaken within mesophilic forest and shiblyak habitats, while 25 trapping days were completed within the mesophilic meadow and steppefied meadow, juniper woodland and agricultural land. A conversion factor developed by Ravkin and Livanov, 2008 (as cited in Ref. 11.9) was used to determine population density for each species recorded.

Small insect eating mammals (excluding moles, and hedgehogs) were counted using cylinder traps. Five cylinders were installed every 50 m along a 15 cm high polyethylene fence in accordance with the method described in Ravkin and Livanov, 2008 (as cited in Ref. 11.9). Traps were placed for 10 days within both the shiblyak and mesophilic forest, whilst 5 trapping days were completed in the steppefied meadow. A conversion factor developed by Ravkin and Livanov, 2008 (as cited in Ref. 11.9) was used to determine population density for these species.

Bats were recorded through visual observation at dusk (sound detectors were not employed for survey). Additionally, structures such as trees and buildings located along the Pipeline and landfall facilities construction footprint (excluding the micro-tunnel area) assessed for their bat roost potential.
Concerning carnivores and other large mammals, information on the presence, distribution, and habitat preference of these species was gathered through sightings of individuals and recording of animal signs (e.g. burrows, snuffle holes, tracks, faeces, etc.) during the walked and driven transects. The population density of species recorded was determined using a formula based on the distance of each transect and number of interaction per species noted.

2012 Surveys

The 2012 surveys were focussed on assessing the suitability for and recording the presence and behaviour of mammals within habitats within the Pipeline and landfall facilities construction footprint (excluding the micro-tunnel area).

As well as sightings of species, surveyors searched for and recorded mammal field signs (such as footprints, mammal paths feeding remains, droppings, and burrows or holes which may have been used by mammals). A single dusk survey was completed when emerging nocturnal species (such as bats) are best recorded.

In addition, surveyors assessed potential structures, including trees and buildings (where appropriate), for their potential to support roosting bats. Trees were classified in accordance with guidance provided by the Bat Conservation Trust (UK) (Ref. 11.10).

2013 Surveys

The 2013 survey repeated the methodology of the 2012 survey, although it focused on the access road options under consideration at the time of the survey (Figure 11.4).

11.4.4.2 Habitat Characterisation according to IFC PS6

As required by IFC PS6, each habitat type is assessed as either modified or natural habitat. These are defined by IFC PS6 (Ref. 11.11) as follows:

Modified habitats are areas that may contain a large proportion of plant and/or animal species of non-native origin, and/or where human activity has substantially modified an area’s primary ecological functions and species composition. Modified habitats may include areas managed for agriculture, forest plantations, reclaimed coastal zones, and reclaimed wetlands.

Natural habitats are areas composed of viable assemblages of plant and/or animal species of largely native origin, and/or where human activity has not essentially modified an area’s primary ecological functions and species composition.

A subset of the above two habitat groupings represent either modified or natural habitat which is of particular ecological importance, termed ‘critical habitat’. This classification is of importance in the determination of the extent and type of mitigation measures required. A separate critical habitat assessment was undertaken to identify areas of this type and is presented in Appendix 11.1, the conclusions of which are integrated into this chapter in the relevant sections.
11.4.5 Data Assumptions and Limitations

11.4.5.1 Habitats and Flora

The optimal period for habitat and botanical survey is generally between April and August, when the majority of plant species are apparent and critical identification features such as flowers and seeds are observable. The 2011 surveys, undertaken between April and July, 2012 surveys, undertaken during August and 2013 surveys, undertaken during June, are therefore likely to have captured a large proportion of the plant species present within the Study Area.

It is acknowledged that the Study Area is relatively floristically diverse and therefore contains plants with a range of flowering strategies (early or late flowering plants). While a small proportion of species may therefore not have been recorded or were under-recorded, the survey timings are not considered a limitation as sufficient information has been gathered to classify habitats and identify their dominant and indicator species.

In terms of red list plant species, secondary data has provided sufficient information to identify which species are likely to be present within the Study Area. Primary data (field surveys), have been undertaken at an appropriate time of year for identifying these species, and have covered a representative proportion of the Study Area, including the proposed Pipeline, landfall facilities, and access roads.

Sufficient data has therefore been gathered to determine the type of habitats, their distribution, and presence (or potential presence) of red list plants within the Study Area.

11.4.5.2 Fauna

Invertebrates

The invertebrates potentially present within the Study Area exhibit a variety of lifecycles, with optimum survey periods for species varying between March and September. The 2012 invertebrate survey (the only survey where invertebrates were surveyed) was undertaken during a six day period during August 2012, is therefore likely to have missed or under-recorded a large proportion of the invertebrates potentially present within the Study Area.

Therefore, species presence or likely absence from within the Study Area has largely been completed through a combination of secondary data sources and based on habitat suitability assessments. The potential presence of threatened invertebrate species was further investigated through consultation with an invertebrate specialist from Kuban State University.

In combination, the primary and secondary data has provided sufficient information to determine with confidence the presence or absence of habitats suitable to support populations of red list invertebrates within the Study Area.
Amphibians and Reptiles

Timing of Surveys

The active period for amphibians and reptiles is largely between March and October. The optimal survey period is generally during cooler months (such as March, April, May and September – mid-October). Surveys were undertaken during April and July (2011), August (2012), and June and October – November (2013). Therefore, the surveys were generally conducted during the main active period, although not always at an optimal time of year.

The 2013 targeted Nikolski’s tortoise survey undertaken by Dr. Leontyeva and team, encountered cold, unseasonal weather in late September and early October. The temperatures experienced at this time were considered by Dr. Leontyeva low enough to prompt a potentially significant proportion of the local tortoise population to go in to hibernation early. This view was confirmed through survey, which revealed that a number of tortoises were already beginning to ‘dig-in’ for hibernation. The weather conditions are therefore likely to have reduced the number of active tortoises within the Tortoise Survey Area, and their numbers are therefore likely to have been under-recorded.

Methods Employed

The walked transect method employed for all reptile surveys, while relatively effective at recording larger reptiles such as Nikolski’s tortoise, can under record smaller species and those which are highly sensitive to human presence (such as lizards and some snake species). A proportion of reptile species may therefore have been missed or under-recorded during the field survey.

Implications for the ESIA

The limitations associated with survey timing and methods have been addressed by:

- Employing a relatively high survey effort (61 days of transect surveys over the course of the three year survey period). This included 11 days in 2011, 6 days in 2012, and 40 days in 2013. The repeat visits over a three-year period increase the likelihood of presence or absence of species being confirmed; and

- Undertaking a thorough review of secondary data sources, including consultation with Dr Olga Leontyeva, a recognised national expert in herpetology from Moscow State University (see ‘Herpetofauna’ within Section 11.5.1.3).

The methods employed during the field surveys combined with the data gathered through the review of secondary data, are considered sufficient to determine the presence or likely absence of various species of reptile, to assess species population densities, and to assess the likely effects of the Project on these species.

Birds

Within the Study Area, birds are present throughout the year, either breeding (peak periods are between March and July inclusive), on migration (the spring migration occurs between mid-February and mid-June and the autumn migration between mid-July and mid-November), or
overwintering (overwintering birds generally arrive in approximately October and leave in March). The 2011 field surveys (undertaken between April and June) would therefore have recorded a sample of breeding birds and spring migrants although they would have missed overwintering birds. The field surveys in 2012 (August) and 2013 (June) would have largely recorded middle to late season breeders and the last of the spring migrants.

The limitations inherent in the timing of the field survey have been mitigated for through the provision of secondary data which have provided context to the field survey data.

The terrestrial ecology baseline for birds presented in this chapter is therefore considered to be an accurate representation of bird species composition and habitat occupation within the Study Area.

**Mammals**

Mammal species potentially present within the Study Area are generally most active between March and September when mating, rearing of young, and foraging activity occur. The field surveys in 2011 (April - June), 2012 (August) and 2013 (June) were therefore undertaken at an appropriate time for recording mammals. However, due to the fact that larger mammals are highly mobile and may be transient within the Study Area at certain times, these species could potentially have been missed or under-recorded during the transect surveys.

The limitations in terms of survey timing and duration have been addressed through supplementing field survey data with a thorough literature review. The secondary data has provided additional information with which to predict species’ presence or likely absence from within the Study Area throughout the year, while the field survey information has provided data to determine their likely presence or absence from the Study Area based on habitat preferences.

In terms of bats, ultra-sound detection and recording was not employed during surveys. Bats are difficult to record and identify without this equipment and individuals may therefore have been missed or under-recorded. The identification or differentiation between species of bat which were observed also could not be undertaken.

Physical data has been gathered to determine whether roosting bats are likely to be directly affected by the Project. Furthermore, sufficient information has been gathered to identify potential commuting and foraging habitat for bats. Finally, secondary data sources have allowed the determination of those species of bat which are likely to be present within the Study Area (based on their known range and habitat preferences).

### 11.5 Baseline Characteristics

The baseline information in this section summarises the findings of the 2011, 2012, and 2013 surveys and the secondary data reviewed for the Project. It characterises the ecology of the Study Area.
11.5.1 Study Area

11.5.1.1 Designated Sites

Special Protected Natural Areas

The Utrish SPNA is located approximately 3.8 km south-east of the Pipeline construction corridor (see Figure 11.1). It covers an area of approximately 10,800 ha and includes both onshore (9225 ha) and offshore (783 ha) areas.

Habitats and Flora

The onshore portion of the Utrish SPNA is located at the north-western extremity of the Caucasus mountain range and abuts the Black Sea along its western boundary. Two bands of vegetation predominate within the site, largely the result of the altitudinal differentiation within the area and the mountainous terrain (the influence of slope aspect and steepness). The vegetation of the lower altitudinal belt (0 – 200 m) is characterised by xerophilous (shiblyak) vegetation comprising juniper Juniperus sp. and pubescent oak Quercus pubescens. The vegetation of the upper altitudinal belt (150 m – 500 m) is characterised by mesophilic broad-leaved forests of oriental beech Fagus orientalis, oriental hornbeam Carpus orientalis, sessile oak Quercus petraea and ash Fraxinus excelsior (Ref. 11.12).

The SPNA supports a total of 117 endemic plant species, nine percent of the total number of plant species recorded within the SPNA (Ref. 11.12). The reserve does not support plant species listed as threatened (Vulnerable and above) on the IUCN RL, but it does support 72 species listed as threatened on the RDB RF or the RDB KK.

Invertebrates

The Utrish SPNA supports a large variety of invertebrate species. This includes 3 species listed as threatened on the IUCN RL and 51 species listed as threatened on either the RDB RF or RDB KK (Ref. 11.12). The juniper woodland, shiblyak and steppefied meadow contained within the reserve are of particular importance for sustaining populations of threatened insects which are dependent on the food plants contained within these habitat types.

Herpetofauna

The Utrish SPNA supports at least 14 species of reptile and eight species of amphibian. It is of particular importance to Nikolski’s tortoise, a species listed as CR on the IUCN RL. It has been estimated that the SPNA supports a population of between 5000 – 6000 Nikolski’s tortoise (or ca. 20 to 30 percent of the global population of this species) (Ref 11.12). It also supports two other threatened species of reptile listed on the RDB KK (the Aesculapian ratsnake Elaphe longissima and European glass lizard Pseudopus apodus) and three species of threatened amphibian listed on the RDB RF or RDB KK (southern crested newt Triturus karelini, smooth newt Lissotriton vulgaris lantzi and Caucasian toad Bufo verrucosissimus).
**Birds**

The Utrish SPNA supports approximately 157 species of bird belonging to 43 families of 19 orders (Ref. 11.12). It supports a variety of species throughout the year, including breeding, over-wintering, and transient species that use the site as a stop-over point on migration. The site supports a number of species which are listed on the IUCN RL (e.g. peregrine falcon *Falco peregrinus*) RDB RF and RDB KK (e.g. short-toed snake eagle *Circaetus gallicus*, booted eagle *Hieraaetus pennatus*, oystercatcher *Haematopus ostralegus*, gull-billed tern *Gelochelidon nilotica*, little tern *Stern albinoris*, wood lark *Lullula arborea* and rufous-tailed rock thrush *Monticola saxatilis*).

**Mammals**

Utrish SPNA supports approximately 45 species of mammal (Ref. 11.12). This includes five species of bat listed as threatened on the RDB RF or RDB KK: barbastelle *Barbastella barbastellus*, lesser mouse-eared bat *Myotis blythii*, pond bat *Myotis dasycneme*, Bechstein's bat *Myotis bechsteinii*, and Leisler's bat *Nyctalus leisleri*.

**Protective Forest Areas**

All forest or woodland habitat within the Study Area are identified as ‘protective forests’, as defined within the Forest Code of the Russian Federation (Ref. 11.13). This includes all mesophilic forest, shiblyak and juniper woodland. These forests are recognised as important features within the environment, as they perform important functions, such as protection of water resources and soils, and recreational spaces for local communities. This designation is not strictly related to the forest's intrinsic ‘biodiversity value’, but rather is associated with the ecological function it provides.

**Anapa Resort Town Sanitary Protection Area**

The town of Anapa was assigned the status of a federal resort by President Decree No. 1954 dated September 22, 1994. It was given this status due to its recreational value as a ‘health improving’ (spa) resort area. This designated area is referred to as a Sanitary Protection Area.

The centre of the Pipeline construction corridor is located approximately 500 m from the boundary of the second and third exclusion zones of the Sanitary Protection Area of Anapa (Figure 11.1).

It is acknowledged that habitats and plant and animal species are important components of the Sanitary Protection Area and contribute to the town of Anapa’s status as a resort area. The potential for the Project to affect these ‘component parts’ of the Sanitary Protection Area is considered in this chapter and any potential for indirect effects to the designated site will therefore be accounted for. However, as this Sanitary Protection Area is designated for its amenity and recreational value, it is not considered further in this chapter.
11.5.1.2 Habitats and Flora

Introduction

The Study Area is located in the foothills between the Greater Caucasus mountain range and the Azov-Kuban lowland. It largely comprises an undulating plateau extending north-east away from a steep coastal cliff with the shoreline of the Black Sea at its base. The plateau has been eroded by streams; forming steep gullies in places (see Chapter 7 Physical and Geophysical Environment). The Pipeline crosses two small watercourses within the Study Area, which include the Shingar River (1.5 - 2.5 m wide) and an unnamed tributary of the Sukko River (see Chapter 8 Soils, Groundwater and Surface Waters).

The Study Area falls within a typically Mediterranean climatic zone, and it experiences relatively warm and moist winters and hot dry summers. On average, the warmest months are June to September with a maximum monthly average temperature of 21.0 °C. The coolest are November to March, with a minimum average temperature of 4.4 °C. The annual average precipitation is 539 millimetres (mm) (an average of 45 mm per month), mainly in the form of rain. The maximum recorded daily precipitation is 85.9 mm. There is relatively little seasonal variation in precipitation, with the greatest amount occurring during the months of November, December and January.

A diversity of soil types exists within the Study Area, which reflects the variety of bedrock and soil forming processes that underlie it (Ref. 11.9). Soils covering higher slopes and ridges are typically formed by the weathering and re-deposition of calcareous argillites and interbedded sandstones and siltstones. Soils encountered within river valley systems typically comprise weathered calcareous marls, interbedded limestones, siltstones and shales. Valley bottoms comprise variable gravel and sand deposits with occasional layers of clays and loam material interbedded in the coarser grained material (Ref. 11.9).

The topography, soil types, climate, as well as anthropogenic influence, has created relatively diverse conditions on which a range of habitat types have developed (Ref. 11.9). This has in turn created diverse conditions within which various plants and animals, including species of conservation concern, can inhabit. The following section describes these habitats and presents those species which either have been, or have the potential to be, present within the Study Area.

Habitats and Flora

The Study Area supports a range of relic arid sub-Mediterranean vegetation types that have a restricted range within Russia. Surveys undertaken in 2011 recorded a total of eight natural habitats are areas composed of viable assemblages of plant and/or animal species of largely native origin, and/or where human activity has not essentially modified an area’s primary ecological functions and species composition. As per IFC PS 6 (Ref. 11.38).
and two modified terrestrial habitat types within the Study Area (Ref. 11.9). These are: xerophilous shrub woodland (also known as shiblyak), mesophilic forest, juniper woodland, secondary steppified meadow, mesophilic meadow, tomillyar, rocky outcrops, coastal shingle and agricultural habitats. In addition, running water habitat is present in the form of two watercourses. These habitat types are discussed in further detail, below and their location and extent mapped on Figure 11.6. Table 11.4 presents the area of each habitat type within the Study Area.

* Refer to Table 11.33 for area of loss within the project footprint

Surveys recorded approximately 340 species of plant belonging to 75 families within the Study Area (Ref. 11.9). This data revealed that species diversity is highest in the Asteraceae (39 species), Poaceae (36 species), Fabaceae (23 species), Lamiaceae (23 species), and Brassicaceae (16 species) families. The average species richness with the various plant communities within the Study Area varies between nine species per 100 m² on the eroded slopes to 22 species per 100 m² within the tomillyar habitat.

---

5 Modified habitats are areas that may contain a large proportion of plant and/or animal species of non-native origin, and / or where human activity has substantially modified an area’s primary ecological functions and species composition. As per IFC PS 6 (Ref. 11.38).
**Shiblyak**

Shiblyak woodland is the dominant woodland type in the Study Area. It comprises dwarf woodland and shrub vegetation communities 4 m – 6 m in height. Shiblyak is characterised by xerophytic species that are adapted for surviving in dry environments (Florov 1926, Maleev 1931, Povarnitsyn 1940, as is cited in Ref. 11.9). These woodlands are diverse in structure, floristically rich and are dominated by woody species including pubescent oak *Quercus pubescens*, oriental hornbeam *Carpinus orientalis* and juniper species. Occasionally, other species such as Pitsynda pine *Pinus pityusa*, common pine *Pinus sylvestris*, field maple *Acer campestre*, European alder *Alnus glutinosa* and Mt. Atlas mastic tree *Pistacia mutica* are present. Within the understory, European cornel *Cornus mas* is dominant. Species including blood twig dogwood *Thelycrania australis* and common privet *Ligustrum vulgare* are also occasionally present. Within the ground layer, herbaceous species include wood avens *Geum urbanum*, forest violet *Viola silvestris*, Kavakh peony *Paeonia kavachensis* and common primrose *Primula vulgaris*. Grasses include heath false brome *Brachypodium pinnatum*, cocksfoot *Dactylis glomerata* and Japanese bromegrass *Bromus japonicus* (Ref. 11.9).

The shiblyak habitat within the Study Area comprises predominantly native plant species and there is little evidence of human modification of this habitat type. Shiblyak is therefore considered to be a natural habitat according to IFC PS 6 criteria.

**Mesophilic Forest**

Within the Study Area, mesophilic forest is restricted to the riverine floodplains and valleys of the Graphova and Kblerova gaps, as well as along the floodplain of the Shingar River (refer to Figure 11.6). The woodland reaches a height of approximately 14 m – 16 m and is dominated by woody species including European alder and almond-leaved willow *Salix triandra*, with locally dominant stands of European ash *Fraxinus excelsior*, Caucasian pear *Pyrus caucasica* and field maple. The understory comprises predominantly Eurasian cornel, blood twig dogwood and common privet. Localised stands of common hazel *Corylus avellana*, European elder *Sambucus nigra* and bladdernut *Stephylea pinnata* are also present. The ground layer is relatively dense and comprises bishop's weed *Aegopodium podagraria*, common nettle *Urtica dioica*, wood avens, white dead-nettle *Lamium album* and cleavers *Gallium aparine*. In the spring, forb species include Siberian squill *Scilla sibirica*, lesser celandine *Ficaria verna*, Arum lily *Arum orientale*, common primrose and Greek corydalis *Corydalis marschalliana*, as well as orchid species such as man orchid *Orchis mascula*.

The mesophilic forest within the Study Area comprises predominantly native plant species with little evidence of human modification of this habitat type. It is therefore considered to be a natural habitat in accordance with IFC PS 6 criteria.

**Juniper Woodland**

Within the Study Area, juniper woodland mainly occurs on the coastal cliffs, although other isolated stands are present. Juniper woodland is a relatively heterogeneous community, dominated in the canopy by juniper species, with abundant pubescent oak and oriental hornbeam. Within the shrub layer, southern sumac *Rhus copallinum*, common privet, Etruscan honeysuckle *Lonicera etrusca*, evergreen jasmine *Jasminum fruticans* and bladder fern
Cystopteris dickieana are relatively abundant. The ground-layer is diverse and comprises species including felty germander Teucrium polium, wall germander Teucrium chamaedrys, sword-leaf inula Inula ensifolia, goldendrop Onosma polyphyllum, common ephedra Ephedra distachya and bindweed Convovulus cantabrica. During the spring months, the more open areas within the juniper woodland contain species including mouse hyacinth Muscari muscarini, dwarf flag iris Iris pumila and Breckland speedwell Veronica praecox.

An isolated area of sparse juniper woodland is present along the Pipeline route, bordered by two areas of agricultural land (refer to Figure 11.6). This area contains species as listed for the habitat above, in addition to common pine, blackthorn Prunus spinosa, goat’s beard Tragopogon graminifolius and melic grass Melica transsilvanica.

The juniper woodland within the Study Area comprises predominantly native plant species with little evidence of human modification of this habitat type. It is therefore considered to be a natural habitat in accordance with IFC PS 6 criteria.

Tomillyar

Tomillyar is relatively fragmented and scarce within the Study Area, largely confined to the coastal cliffs (Ref. 11.9). The habitat comprises herbaceous plant communities with the majority of species associated with dry and hot environments. Dominant species include felty germander, Marshall’s thyme Thymus marschallianus, sage-leaf mullein Phlomis tuberosa and goldendrop. Grass species include melic grass Melica spp., cocksfoot, and golden feather grass Stipa pulcherrima. Tomillyar is generally species-rich, containing on average 13 – 15 species per m². The vegetation structure is also relatively diverse, comprising three different height tiers. The first tier is generally fragmented and comprises grasses and herbs such as sage-leaf mullein and pyramidal orchid Anacamptis pyramidalis. The second tier is represented by medium-height herbs including felty germander and thin-leaved flax Linum tenuifolium, while the third tier is represented by creeping or low growing species including Thymus helendzicus, Marshall’s thyme, and sprawling needle sunrose Fumana procumbens. In the spring, species including mouse hyacinth Hyacinthus orientalis and reticulated iris Iris reticulata are evident.

The tomillyar within the Study Area comprises predominantly native plant species with limited evidence of human modification. It is therefore considered to be a natural habitat in accordance with IFC PS 6 criteria.

Secondary Steppefied Meadow

Secondary steppefied meadow occupies a relatively large proportion of the Study Area. They are areas dominated by grasses and herbaceous species that were previously agricultural land (i.e. former vineyards, orchards and fields), which have been derelict for some time.

The dominant grasses within these areas include crested wheatgrass Agropyron pectiniforme, couch grass Elytrigia repens, Japanese brome, cock’s-foot, and bushgrass Calamagrostis epigeios. Grasses make up approximately 75-80 percent of the sward within these areas. Abundant forbs within the meadow areas include blue daisy Cichorium intybus, lady's bedstraw Galium verum and British inula Inula britannica. Threatened forbs found within this habitat type include monkey orchid Orchis simia and pyramidal orchid. Shrub species contained within the
meadow areas include common smoke tree *Cotinus coggygria*, dog rose *Rosa canina*, young specimens of Pubescent oak and juniper.

Secondary steppe meadow areas used to be agricultural land and so have been modified to a large extent. The habitat in its current condition does however contain predominantly native plant species which are representative of natural meadow communities. However, as this habitat is essentially modified from its natural (or original) state through human intervention (and was most likely modified from shiblyak woodland in the majority of areas) it is considered to be modified habitat in accordance with IFC PS 6 criteria.

**Mesophilic meadow**

Within the Study Area, mesophilic meadow is rare. Thin strips of the habitat are located along the river floodplains, predominantly within the Graphova and Kiblerova valleys. These vegetation communities are typical of periodically inundated soils which support plants favouring nutrient-rich environments. Within this habitat type, three different plant sub-communities were recorded: a grass-forb sub-community, a forb-dominant sub-community, and a sub-community comprising almost entirely of plants belonging to the family Fabiaceae (Ref. 11.9).

Approximately 85-90 percent of the vegetation within the grass-forb sub-community comprises grasses. The vegetation structure comprised roughly four tiers. The first tier contains taller grasses and forbs including velvet mullein *Verbascum Thapsus*, wild sunflower *Verbisina enclioides*, Fuller’s teasel *Dipsacus fullonum* and common agrimony *Agrimonia eupatoria*. The second tier contains lower growing grasses and forbs, such as bush grass, cocksfoot, yarrow *Achillea millefolium* and common agrimony. The third tier comprises predominantly creeping forbs, including cinquefoil *Potentilla reptans* and wild strawberry *Fragaria vesca*. The fourth tier is largely comprises of moss species.

The forb-dominant sub-community comprises various forbs including blue daisy, wild carrot *Daucus carota*, Italian aster *Aster amellus* and field daisy *Leucanthemum vulgare*. Smooth-stalked meadow-grass *Poa pratensis*, field brome *Bromus arvensis*, sterile brome *Bromus sterilis* and other grass species are also present. Although rare, monkey orchid has been recorded within this sub-community type at a density of 1-2 plants per 100 m².

The Fabiaceae-dominant plant sub-community is present at the edges of the mesophilic meadow. The dominant species here is crown vetch *Coronilla coronata*, which in places covers 100 percent of the land surface.

The areas of mesophilic meadow within the Study Area comprise predominantly native plant species with limited evidence of human modification to this habitat type. It is therefore considered to be a natural habitat in accordance with IFC PS 6 criteria.

**Rocky Outcrops**

Fragmented areas of rock or scree habitat are restricted to areas of the coastal cliffs. Shrubs growing within these areas include southern sumac, Jerusalem thorn *Parkinsonia aculeate*, bladder fern and common smoke tree. There is a relatively high diversity of herbaceous species growing within these areas, with species including dog’s parsley *Seseli ponticum*, sword-leaf
inula, pyramidal orchid, thorny-head lamira *Lamya echinocephala*, goldilocks *Linosyris vulgaris* and felty germander. Species diversity within these areas is 5 – 10 per m².

The areas of rocky outcrops within the Study Area comprise predominantly native plant species with limited evidence of human modification to this habitat type. It is therefore considered to be a **natural habitat** in accordance with IFC PS 6 criteria.

**Coastal Shingle**

Coastal shingle exists along the coastal strip to the west of the Study Area. No plant species were recorded within these areas.

These areas are subject to limited modification through human activity and are therefore considered to be a **natural habitat** in accordance with IFC PS 6 criteria.

**Urban and Agricultural Habitats**

Urban and agricultural habitats form a considerable part of the Study Area and include vineyards, orchards, fallows and other habitats associated with human activity (e.g. roads) (Ref. 11.9). Within these areas, fragmented grass-forb communities are present (largely adjacent to the access roads servicing the abandoned vineyards) comprising wormwood *Artemisia absinthium*, Bermuda grass *Cynodon dactylon*, yellow foxtail grass *Setaria glauca*, green foxtail grass *Setaria viridis*, bristle thistle *Carduus acanthoides*, field bindweed *Convolvulus arvensis*, common nettle, Mediterranean elder *Sambucus ebulus* and horse sorrel *Rumex confertus*.

The areas of agricultural habitats have been heavily modified through human influence. Although these areas contain pockets of semi-natural vegetation, they are considered to be a **modified habitat** in accordance with IFC PS 6.

**Running Water**

The landfall section of the Project crosses two small watercourses, the Shingar River and an unnamed tributary of the Sukko River (Figure 11.7). Both watercourses have the characteristics of upper course streams, being narrow (less than 3 m), occur in valleys with relatively steep gradients and exhibit short response time to rainfall events. These watercourses therefore have episodic high and low flows in response to seasonal rainfall patterns. In summer, the channels partially dry-out to leave intermittent pools along the rivers’ reach. Within the Graphova gap, at least two pools have been enlarged through a combination of excavation and embankment. Both pools appear to hold water all year, even when the remainder of the watercourse has dried.

The phytoplankton communities found within the Study Area reflect the physical characteristics of the watercourses. Their low species richness and abundance are typical of watercourses in their upper courses and also possibly reflect the low water temperatures and mineral concentrations (phytoplankton and zooplankton communities tend to be generally best developed in lacustrine environments or slow flowing rivers). Species recorded include green algae, diatoms (which were dominant) and blue-green algae (which were far less prevalent).
Average phytoplankton biomass in the Shingar River was 0.41 g/m³ and 0.37 (g/m³) in the unnamed tributary of the Sukko River.

As many zooplankton species feed on phytoplankton, the low density of phytoplankton is reflected by low zooplankton populations within the two watercourses. The composition of the zooplankton associated with the two watercourses comprised a mixture of Rotifers (six species), Copepods and Cladocerans. Average zooplankton biomass in the Shingar River was 0.13 g/m³ and 0.11 g/m³ in the unnamed tributary of the Sukko.

The running water within the Study Area is subject to limited modification through human activity and is therefore considered to be a natural habitat in accordance with IFC PS 6 criteria.

Red List Plant Species

Secondary data indicates that the Study Area has the potential to support 28 red list plants species (Ref 11.2, Ref. 11.4). This includes 28 plant species listed in the RDB KK, 14 on the RDB RF and two on the IUCN RL (some species are listed in more than one list or book). In total, the three surveys recorded 26 different red list plant species within the Study Area (Figure 11.6). Table 11.5 presents all red list plants recorded during the 2011, 2012 and 2013 surveys, along with the habitats within which they are likely to occur.

Complete.

The density of red list plant species for each habitat type was estimated during the 2011 surveys for 14 of the total 26 species; the results presented within Table 11.6 below. Red list species were recorded within all habitat types apart from the coastal shingle and agricultural habitats. The greatest diversity of red list flora was found within the juniper woodlands (8 species), tomlilyar (4 species) and rocky outcrops (five species).

11.5.1.3 Fauna

Introduction

The mosaic of habitats described in the previous section, as well as their relative floristic diversity, provide suitable foraging, breeding, and sheltering habitat for a range of fauna (Ref. 11.9). During surveys undertaken in 2011, 2012, and 2013, a variety of invertebrate, amphibian reptile, bird and mammal species were recorded across the habitat types present within the Study Area. The results of these surveys are detailed below.

Invertebrates

According to secondary data, 43 red list invertebrate species have the potential to be present within the Study Area. All 43 are listed on the RDB KK and nine on the RDB RF. Three species have been assessed as threatened on the IUCN RL. Table 11.7 indicates their habitat preference and conservation status.

Targeted invertebrate surveys were not undertaken in the 2011 and 2013 surveys. During the 2012 surveys, six red list invertebrate species were recorded within the Study Area. These species are highlighted in bold in Table 11.7 and their locations are shown in Figure 11.8.

Subsequent to the field surveys, a meeting was held with Dr Semen Kustov from the Kuban State University to discuss the known distribution and ecology of the threatened species of invertebrate listed in Table 11.7. The aim of this meeting was to obtain additional information on the likelihood of these species to be present and on their habitat requirements. Based on the information obtained during the meeting, a number of these species are considered unlikely to be present within the Study Area:

- *Cardiophorus juniperinus* - Very rare species only known from two locations within Utrish. Requires juniper deadwood habitats occurring on the ground;
- *Platypterynx auritus* – Has only been recorded within Utrish;
- *Kretania zamotajlovi* - Very rare species which has only been recorded from 3 locations within Utrish. Populations have been reduced by collectors and possibly number less than 500 individuals;
- *Zygaena laeta* – Only known from one site near Novorossiysk and has not been recorded since the 1980s. Possibly extinct; and
- *Jordanita graeca* – RDB KK record from Utrish is considered likely to be an error as the species is otherwise restricted to lowland habitats on the Taman Peninsula.

Aquatic Macro-invertebrates

The taxa recorded during the 2011 surveys are found in a range of benthic freshwater habitats. The community recorded in both streams included the larvae of caddis flies (Trichoptera), dragonflies (Odonata), mayflies (Ephemeroptera), mysids (Gammaridae) and polychaetes (Polychaeta), many of which are often associated with good quality waters. No red list species were recorded.

Fish

Six species of fish were recorded within the Study Area. Southern riffle minnow was abundant in both watercourses with western transcaucasian gudgeon, colchian minnow and Rodion’s river goby occurring less frequently. In downstream reaches of the Shingar River, Caucasian chub and three-spine stickleback occurred in low numbers. One species has been assessed on the IUCN RL and none are listed on the RDB RF. Rodion’s river goby *Neogobius rhodioni* and Colchis minnow *Phoxinus phoxinus colchicus* are listed on the RDB KK within appendix 3 (Table 11.8).

Herpetofauna (Amphibians and Reptiles)

The woodland, grassland, wet and open habitats, as well as the ecotones (habitat edges) between them, provide suitable habitat for amphibian and reptile species. Desk study information indicated the potential presence of five amphibian and 16 reptile species within the Study Area (Ref. 11.9, Ref. 11.3, and Ref. 11.5). During the field surveys in 2011, 2012 and 2013 a total of five amphibian and 15 species of reptile were recorded (these are shown in **bold** in Table 11.9). Table 11.9 lists all herpetofauna species potentially present within the Study Area and their conservation status.

Two amphibian species and ten reptile species recorded during the field surveys are threatened at the regional, national, and/or international level. In addition, meadow lizard is assessed as Near Threatened by the IUCN. The locations of RDB herpetiles recorded during the 2011, 2012, and 2013 are presented on Figure 11.9 and Figure 11.10.

The preferred habitat of herpetofauna recorded within the Study Area was identified through literature review (Ostrovskikh and Chuskin 1998, Ostrovskikh and Plotnikov 2006, as are cited within Ref. 11.9), through consultation with Dr. Olga Leontyeva, and through observations made during the 2011, 2012 and 2013 field surveys. These are summarised in Table 11.10.

**Notes:** + High probability of habitat occupation; - Low probability of habitat occupations; ‘blank’ Occupation unlikely.

The coastal shingle habitats within the Study Area were shown to support grass snake and tessellated water snake, both of which prey on fish present along the coastal strip (Ref. 11.9). Brauner’s rock lizard was also recorded on the coastal cliffs and rocky outcrops habitat basking and feeding on small invertebrates present within the habitat.

Within the stands of juniper woodland, three species were recorded during field surveys: Nikolski’s tortoise, European glass lizard and Dahl’s whipsnake. In addition to these species, other reptile species including meadow lizard, large whipsnake, and Pallas whipsnake potentially occur within this habitat (Ref. 11.9).

The structure and plant species contained within the areas of tomililyar habitat are relatively similar to that in juniper woodland. Consequently, similar species of reptile are supported by these habitats, including glass lizard, large whipsnake, Dahl’s whipsnake, three-lined lizard and Nikolski’s tortoise (Ref. 11.9).

Within the stands of shiblyak woodland, Nikolski’s tortoise, European glass lizard, Pallas whipsnake, and meadow lizard were recorded during the 2011, 2012 and 2013 surveys. European tree frog was also recorded within this habitat. The shiblyak habitat within the Study Area is structurally and floristically relatively diverse, providing a variety of habitats for reptiles and amphibians to forage, bask, shelter, and breed (Ref. 11.9).

Conditions within the mesophilic woodlands suit reptiles and amphibians that favour moist or wetter environments, including tessellated water snake, grass snake, marsh frog and European tree frog. Meadow lizards and sand lizards were also recorded within these areas during the surveys (Ref. 11.9). Where the mesophilic forest areas grade into mesophilic meadow, species favouring these edge habitats were found. This included tessellated water snake, large whip snake, smooth snake, slow worm, sand lizard, and meadow lizard (Ref. 11.9).

The steppefied secondary meadow was shown to support Nikolski’s tortoise, European glass lizard, meadow lizard, and sand lizard. Although not recorded in these habitat areas during any of the surveys large and Pallas whipsnake, may occur within these areas.
Nikolski’s tortoise is known to occur within agricultural habitats early in the season (April to early May); however, none were recorded in this habitat type during the field surveys. Other species of snake and lizard may be present in agricultural habitats but were also not recorded. Two species of amphibian; green toad and Caucasian toad were recorded in or on the tracks adjacent to the vineyards in August 2013. It is considered that due to the relatively high levels of human disturbance within agricultural habitats, the occurrence of these species is, in general, short-term and episodic (Ref. 11.9). These habitats are thus not considered optimal habitat for many reptile and amphibian species. That said, for opportunistic species, such as the large whipsnake and Pallas whipsnake, the suitability of these areas increases during the orchard and vineyard fruiting periods, as numbers of prey species such as birds and rats increase within these areas at these times (Ref. 11.9).

It is important to note that the distribution of reptile and amphibians within the Study Area changes according to seasonal and climatic variability. In the spring and autumn months, when temperatures are generally cooler, reptiles prefer open habitats where they are able to bask and warm themselves. During the summer months when temperatures are very high and there is a general lack of moisture within open habitats, reptiles will move to the forest areas where it is cooler. Amphibians such as the European tree frog, Eurasian marsh frog, green toad and Caucasian toad will be present in ponds and waterbodies during the breeding season (roughly March – July), but as these ephemeral waterbodies dry up these species will move to adjacent terrestrial habitat (Ref. 11.9).

Based on the surveys undertaken in 2011, the relative abundance of each reptile and amphibian species present within the Study Area was determined. Table 11.11 below summarises this information for each species.

**Herpetile Hibernation Habitat Preference**

All species of reptile and amphibian hibernate, and it is considered that this could happen in all habitat types within the Study Area, with the exception of active vineyards. However, the results of surveys undertaken by Dr. Olga Leontyeva during October – November 2013 (during which 51 individual Nikolski’s tortoise were recorded), suggest that Nikolski’s tortoise may favour hibernation sites near the ecotone between the forested valleys and meadows (see Figure 11.9); during the survey, Dr. Leontyeva stated that these data indicate that individuals are moving into these areas to hibernate over the winter period (Ref. 11.14).

In terms of hibernation habitat preferences for other herpetile species, they will find old animal burrows, cracks in tree roots or other suitable areas (e.g. under large logs, rubbish or under buildings) within grassland or forest areas for hibernation, but generally within areas with suitable vegetation coverage.

The hibernation season will vary slightly from species to species and according to prevailing night-time temperatures. However, in general terms is considered to last from mid-October to mid-April. Nikolski’s tortoise will begin to emerge from hibernation after approximately five consecutive days where night-time temperatures have been above 10°C.

**Nikolski’s Tortoise Population Estimate**

Given the high sensitivity of Nikolski’s tortoise (i.e. listed as internationally Critically Endangered), an attempt was made to determine the size of the population likely to be supported within the Study Area. An estimate was derived from a review of studies undertaken since 1985, and consideration of data obtained during the targeted Nikolski’s tortoise field survey undertaken for the Project by Dr. Olga Leontyeva between October and November 2013.
Studies reviewed included the following:

- Inozemtsev and Pereshkolnik in 1985 (Ref. 11.15);
- Lukina and Sokolenko in 1991 (Ref. 11.16);
- Pestov and Leontyeva in 2011 (Ref. 11.17); and
- Leontyeva et al. in 2012 (Ref. 11.18).

Inozemtsev and Pereshkolnik (1985) state that the species can occur in densities of 0.2 to 0.5 per ha depending on the type and quality of the habitats present. Lukina and Sokolenko (1991) recorded 0.2/ha in Sochi National Park and in the Anapa district on the edge of agricultural land. Based on the total area of ‘suitable’ habitat contained within the Study Area (691 ha, a figure which excludes agricultural and urban habitats which are generally considered to be sub-optimal for supporting tortoises), this would equate to a population of between 138 – 345 individuals for the Study Area.

Pestov and Leontyeva (2011) calculated a range of population densities for different habitat types, based on data from over 300 km of transects completed during 2007-2011 on the Abrau Peninsula (Ref. 11.17). Table 11.12 presents the derived density figures / habitat type (ha).

**Table 11.12 Calculated densities of Nikolski tortoise within the Study Area based on Pestov and Leontyeva (2011)**

</tr>
</tbody>
</table>

Therefore, based on the density data published by Pestov and Leontyeva (2011), the Project Study Area has the potential to support between 437 and 1220 individual tortoises.

The late autumn 2013 survey by Dr. Leontyeva was undertaken to refine the tortoise population estimate for the Study Area (see Section 11.4.4.1). This survey recorded a total of 51 individuals within the Tortoise Survey Area; taking into consideration the seasonal limitations of the survey (see Section 11.4.5.2), it is likely that larger numbers of individuals would be recorded during more suitable survey conditions.
Moreover, the vast majority of the adult individuals recorded (24 of the individuals recorded were juveniles) during the survey were female (21 of 27). Considering that the sex ratio within Nikolski’s tortoise populations has generally been shown to be 1:1 (Ref. 11.19), it can be inferred that at least another 21 males are likely to be present within the Tortoise Survey Area. Therefore, the minimum density of tortoises within the Tortoise Survey Area (130 ha) is likely to be 0.55 individuals per hectare. Extrapolated to the entire Study Area (taken to include approximately 556 ha of suitable habitat) would provide an estimate population size of approximately 350 individuals. However, further survey is recommended to refine this estimate (see Section 11.6.9.4).

The population of Nikolski’s tortoise within the Abrau peninsula has been estimated by Dr. Leontyeva to be in the region of 7000 individuals (Ref. 11.20). If the Study Area is assumed to support a population of 150 to 350 individuals (and potentially more), then the Study Area would support approximately 2 to 5% of total population of the Abrau peninsula; ecologically, this is considered to be a significant portion of the regional population).

Birds

The Study Area consists of a range of habitats that between them support a diverse assemblage of birds. In total, 137 species were recorded during the 2011, 2012 and 2013 bird surveys.

The species are classified by the following ecological status:

- **Resident (R)** – these species are present all year round and breed within the Study Area;
- **Breeding Migrant (BM)** – these species migrate to and breed within the Study Area during the summer months (indicatively April – September); and
- **Non-breeding Migrant (NBM)** – these species do not breed within the Study Area but migrate through the area. These species can be present at any point during the year but the majority would be present during spring (April / May) and autumn (July to October) passage.

None of the species recorded within the Study Area are considered likely to be present during the winter months only. A full species list of birds recorded and their ecological status is included in Table 11.13 below.

**Table 11.13 Species recorded during the 2011, 2012 and 2013 survey and their ecological status on site**

**Breeding Birds**

A total of 107 species were recorded which are considered to breed or possibly breed within the Study Area (Ref. 11.9). Of these, 39 species are thought to be present all year-round and do not migrate. The remaining 68 species breed during the spring and summer months and over-winter in other regions. Species were recorded breeding within all habitats surveyed and the large recorded assemblage is as a result of the diversity of habitats present within the Study Area.

In 2011, comprehensive bird surveys were completed which aimed to record the densities of breeding birds within each terrestrial habitat type. Those species that could be affected by the Project are shown in Table 11.14. Densities of breeding birds recorded within settlements, rocky outcrops and along the shoreline are not shown as these habitat types will not be affected by the Project, although species of conservation concern recorded within these areas are discussed.

**Mesophilic Forest**

The greatest diversity of breeding birds was recorded within the mesophilic forest. However, the assemblage consists largely of fairly widespread and ubiquitous species of woodland and woodland edge birds. Mesophilic woodland in the region is known to support seven species of breeding raptor, of which three: short-toed snake-eagle, booted eagle and red-footed falcon, are of conservation concern (Table 11.14). All three of these species are considered to have the potential to breed in this woodland habitat, although no nests of these species were confirmed on mature trees within the Study Area. All of these species have been confirmed as hunting over the Study Area. Another species of conservation concern, wood lark, breeds within the mesophilic forest. Wood larks were confirmed as breeding within this habitat and are associated with the woodland edges.

**Shiblyak**

Shiblyak supports the second most diverse breeding bird assemblage within the Study Area, with 34 species recorded. However, all of the species recorded are widespread and ubiquitous.
and are typical for this habitat type. No red list species were recorded breeding within this habitat type. The species with the greatest breeding densities were European turtle doves, thrushes and finches. This habitat also provides nesting opportunities for Eurasian nightjar, and two species of bunting: yellowhammer and ortolan bunting.

**Secondary Steppefied Meadow**

Twenty-six species are considered to have nested within this habitat type of which one species: wood lark is of regional conservation concern and listed on the RDB KK. The remaining breeding species are widespread and ubiquitous, typical for this habitat type. The assemblage consists of species that prefer more open habitats with associated scrub and includes: larks, pipits, shrikes, warblers, finches and four species of bunting (corn bunting, yellowhammer, rock bunting and ortolan bunting).

Two species of raptor are considered to have possibly bred within this habitat: western marsh harrier and Montagu's harrier. A female and juvenile of both species were recorded in this suitable breeding habitat in August 2012, although it is possible that all individuals seen were on migration.

**Mesophilic Meadow**

Out of the nine species considered to breed in this habitat type, wood lark is a red list species. The remaining species are widespread and ubiquitous.

**Juniper Woodland with Tomillyar**

Fifteen species were confirmed as breeding within the stands of juniper woodland within the Study Area, although none are red list species. The breeding assemblage consisted of lesser grey shrike, corvids and finches, all of which are widespread and typical for this habitat type.

**Agricultural Habitats**

These consist of vineyards and orchards and associated human habitation and consequently a diverse assemblage of breeding bird species is supported by these habitats. One of these species, wood lark, is listed on the RDB KK. All other birds are common species.

**Other Habitats**

Other habitats surveyed within the Study Area included rocky outcrops, cliff and the coastal strip. These areas supported three red list species: peregrine falcon, European roller, and rufous-tailed rock-thrush. One of these species, European roller, is listed as Near Threatened by the IUCN. All of these species are also listed on the RDB RF and RDB KK.

These habitats do not support aggregations or communities of nesting seabirds (e.g. gulls) as the cliff areas within the Study Area do not contain suitable habitat for these species. Impacts on nesting seabirds are therefore not considered further within this chapter.
Red Listed Breeding Birds

Seven of the bird species that are considered potentially to have bred within the Study Area are listed on the IUCN RL, RDB RF, and / or RDB KK. In addition, a further five species are listed on the appendix 3 of the RDB KK, which are species that are recommended for further research in the region. Table 11.15 includes a summary of their conservation status and their preferred habitats.

Table 11.15 Red list species considered potentially to have bred or potentially bred in the Study Area in 2011, 2012 and 2013.

**Non-breeding Migratory and Overwintering Birds**

The Black Sea coast is a major migration corridor where birds move in a north-west direction in spring and in a south-east direction during autumn. The majority of migrants follow estuarine valleys of rivers flowing into the Black Sea, where they stop to feed along the coast (Ref. 11.6).

Spring migration starts in the second or third week of February with spring migration ending in late June. Some species of birds will merely pass over the Study Area for more northerly breeding grounds whilst others migrate to the area to breed. Autumn migration begins from the second week of July and finishes in the second half of November.

A range of species were observed migrating over the Study Area in both spring and autumn. However, the Study Area is not used as a stop-over site for large numbers of birds. Migrating raptors, European bee-eaters and hirundines will feed over the site during migration and it is also probable that the site also supports migrating passerine species (e.g. warblers, thrushes, skrikes, pipits, larks and buntings). The site is not a recognised bottleneck migration site and it does not support large aggregations of staging birds. Wildfowl and wading birds, divers, grebes, gulls and terns were recorded migrating over, and over-wintering on the sea. However, these are discussed further in **Chapter 12 Marine Ecology**.

**Red Listed Non-breeding Migratory and Overwintering Birds**

Five non-breeding migrants of conservation concern were recorded flying over the Study Area. These are shown in Table 11.16.

**Table 11.16 Red Listed Non-breeding Migrants**

The Project Area does not contain habitats that would support significant aggregations of red listed migratory bird species. The Project Area is not identified as a bottleneck migration site or a significant stop over site. The wintering bird assemblages supported by the terrestrial habitats of the Study Area consist of widespread and ubiquitous species of passerine birds. The terrestrial habitats of the Study Area do not offer suitable foraging or roosting opportunities for large aggregations of wintering birds.
Terrestrial Mammals

Secondary data indicates that the Study Area has the potential to support at least 48 species of mammal (Ref. 11.9). These include species from six orders, comprising six species of insectivore, one species of lagomorph, seven species of rodent, 17 species of bat (Chiroptera), 10 species of carnivore and three species of artiodactyla (Ref. 11.9). Table 11.17 presents these species and provides their classifications on the relevant IUCN RL and RDBs.
