**Complete.**

**Insectivora**

During the course of surveys in 2011, only the Caucasian common shrew was recorded. However during 2012, signs of both Caucasian mole and northern white-breasted hedgehog were noted.

Densities for Caucasian shrew were determined, with the species recorded within the shiblyak and mesophilic forest at densities of 20 individuals per ha, and 59 individuals per ha, respectively.

Signs of the Caucasian mole and northern white-breasted hedgehog were only recorded during the 2012 surveys. Evidence (droppings) of hedgehog was found along the cliff-top path and adjacent to shiblyak. This species is likely to occur throughout the Study Area, but at relatively
low densities. Evidence (footprints and mounds) of Caucasian mole were found throughout the agricultural habitat and also along streambed within mesophilic forest.

The absence of all other insectivora from the Study Area cannot be absolutely ruled out, although considering that they have not been recorded during the 2011, 2012 and 2013 surveys, it is assumed that these species are either likely absent from the Study Area or present in low numbers.

**Chiroptera**

Commuting and foraging bats were observed in the evening during both the 2011 and 2012 field survey. However, as no trapping or ultra-sound survey methods were employed during the survey, the majority of bats could not be identified to genus or species level. One common pipistrelle was however caught in the hand near to the settlement of Sukko during the 2011 surveys.

Suitable foraging and commuting habitat for bats exists across the majority of the Study Area, with the mesophilic forest, shiblyak, vineyards and meadow areas providing excellent opportunity for a variety of bat species to forage. The edges of these habitats and linear features within the landscape, including rivers, tree lines, and hedgerows, provide suitable commuting routes for bats. Bats have the potential to commute up to 20 km (e.g. barbastelle) from a roost site whilst foraging and commuting (Ref. 11.23).

Suitable habitat for supporting roosting bats is present within the Study Area and includes mature trees within the areas of mesophilic forest and buildings within the areas of human settlement. During the 2012 field surveys, bat droppings were found within a disused concrete building located along the valley to the south of the Study Area (see legend labelled “Chiroptera” on Figure 11.8). In addition, other disused vineyard buildings were assessed as being suitable for roosting bats.

The 2012 surveys observed approximately nine trees present within the mesophilic forest which exhibited some, albeit relatively low potential for supporting roosting bats. The potential for these trees to support roosting bats was assessed as low as they lacked favourable features such as deep hollows, cracks, or crevices within which significant number of bats could roost. These trees were considered to be suitable as transient summer roosts, supporting individuals or low numbers of bats during the summer months. Due to the lack of favourable features, the trees were unlikely to be used as hibernation or maternity roosts by bats.

All threatened mammal species potentially present within the Project Area are bats. These include: barbastelle (RDB KK (2)), lesser noctule (RDB KK (2)), pond bat (RDB KK (2)) and Bechstein’s bat (RDB KK (2)).

**Rodentia**

The 2011, 2012 and 2013 surveys recorded seven species of rodent within the Study Area: greater blind mole rat, forest dormouse, brown rat, house mouse, lesser wood mouse, striped field mouse and common vole. Evidence of brown rat and house mouse were recorded within the settlement areas in 2012. None of the Rodentia recorded are red list species.
The 2011 survey, which employed small mammal traps to assess species density within the Study Area, recorded and determined the density of four species of rodent. These results are presented in Table 11.18 below.

</table>

The 2011 surveys recorded greater blind mole rat within the secondary steppefied meadow where, in places, individuals were recorded at densities of 1 – 1.3 individuals per m². Relatively large numbers of individuals were also recorded within the mesophilic meadow and steppefied agricultural habitats.

The presence of other rodents potentially present within the Study Area, but not recorded during field survey, cannot be ruled out with absolute certainty. However, as they were not recorded during the 2011, 2012 and 2013 surveys, these species are likely to be either present in low numbers or absent from the Study Area.

*Lagomorpha*

Evidence of European hare was recorded only during the 2012 surveys, where droppings were noted throughout the agricultural habitats. European rabbit was recorded within the 2013 Study Area with droppings and warrens noted along all of the possible access tracks as well as in the juniper woodland. Adult animals were recorded twice during the 2013 survey work.

*Carnivora*

None of the carnivores potentially present within the Study Area are classified as threatened by the IUCN, RDB RF, or RDB KK, although Caucasian wildcat is listed as Rare (3) on the RDB RF.

The 2011, 2012 and 2013 surveys recorded nine species of carnivore within the Study Area; grey wolf, golden jackal, red fox, raccoon dog, common racoon, least weasel, pine marten,
beech marten, and Eurasian badger. Evidence of these animals was generally restricted to signs (e.g. bones, footprints and faeces).

Definitive evidence of the Caucasian wildcat was not recorded during any of the field surveys and this species is considered to be likely absent from the Study Area.

Artiodactyla

Evidence of wild boar was recorded during the 2013 surveys, with tracks of a single adult and 2 – 3 yearlings recorded within the mesophilic forest. This species is common within the forest areas on the slope of ravines and gullies located to the east of Varvarovka village.

Evidence and sightings of roe deer and red deer were recorded during the 2011 surveys. A roe deer skull was found during the 2012 survey in addition to droppings and prints in areas of the vineyards, woodlands and along the access tracks. Evidence of deer was not noted during the 2013 surveys.

11.5.2 Baseline Summary

No protected sites designated due to nature conservation interest occur within the Study Area. However, Utrish SPNA is located approximately 3.8 km to the south-east of the nearest boundary of the Pipeline construction corridor. In addition, all forest or woodland habitats in the Study Area are classified as ‘protective forests’ under the Forest Code of the Russian Federation.

A range of natural and modified habitats occur within the Study Area. Natural Habitats include shiblyak, mesophilic forest, juniper woodland, mesophilic meadow, tomillyar, rocky outcrops and coastal shingle. Of these, shiblyak covers the greatest land area (431 ha), whereas mesophilic meadow, tomillyar, rocky outcrops, coastal shingle are all limited in extent (all less than 10 ha). Modified habitats present include steppefied meadow (111 ha), as well as urban and agricultural habitats (273 ha). Agricultural habitats are dominated by areas of vineyards.

The habitats in the Study Area support a range of species that have been assessed by the IUCN RL as well as species included with the RDB RF and RDB KK. These include:

- Twenty six plant species listed within the RDB KK, including six assessed as Endangered within the Krasnodar Krai;
- Potentially up to 38 species of terrestrial invertebrates listed within the RDB KK, including three that have been assessed by the IUCN to be Vulnerable at an international level;
- A notable assemblage of herpetofauna, including twelve species included within the RDB KK. This includes Nikolski’s tortoise, which has been assessed by the IUCN as Critically Endangered;
- Six species of bird listed within the RDB KK that may have bred within the Study Area, of which two species, European roller and red-footed falcon have been assessed by the IUCN as Near-threatened;
- Twelve species of bat listed by the RDB KK, of which four are assessed by the IUCN as Near-threatened; and
A range of other mammal species of which one (Caucasian wildcat) is assessed by the RDB RF as rare.

Other receptors such as aquatic invertebrates, fish, phytoplankton and zooplankton are present within the Study Area, but not thought to be of notable conservation value.

**Critical Habitat Summary**

In addition to undertaking an evaluation of the ecological receptors present at the locations described above, for the purposes of undertaking an impact assessment, the IFC PS(6) emphasises the need for there to be particular attention to areas which qualify as 'critical habitat'. The key practical implication of the presence of critical habitat is that any proposed mitigation measures for impacts upon these areas should be designed to result in a net gain in biodiversity.

Appendix 11.1 provides an assessment of critical habitat applicable to the landfall section of the South Stream Offshore Pipeline – Russian Sector. Critical habitat is defined by IFC Performance Standard 6 (PS6) (Ref. 11.11) as areas with high biodiversity value. This includes areas that meet one or more of following criteria:

- **Criterion 1:** Critically Endangered (CR) and / or Endangered (EN) species;
- **Criterion 2:** Endemic and / or restricted-range species;
- **Criterion 3:** Migratory and / or congregatory species;
- **Criterion 4:** Highly threatened and / or unique ecosystems; and
- **Criterion 5:** Key evolutionary processes.

The discrete management unit (DMU) (see Appendix 11.1 for description) has been assessed against these criteria in accordance with PS6 and associated guidance notes (see Table 11.19).

The Project footprint and the Study Area are located within critical habitat defined under Criteria 1 and 2 (see Appendix 11.1 for a description of the DMU) due to the presence of four endangered and endemic species: the plants *Rindera tetraspis* and fern-leaved speedwell, the butterfly Levantine skipper and Nikolski’s tortoise. The presence of two specific habitat types also triggers critical habitat under Criterion 4 (mesophilic forest and tomillyar).

Impacts on key biodiversity values of critical habitat will be afforded particular consideration with regard to mitigation and monitoring protocols, with the aim of demonstrating that there will be a net gain in biodiversity once the proposed measures have been implemented (see mitigation section).

11.6 Impact Assessment

This section identifies and describes the potential impacts of the Project on terrestrial ecology receptors (see Section 11.6.6) and presents mitigation measures. The approach to the impact assessment is outlined below:

- Following the identification of potential terrestrial ecology receptors, the sensitivity of each receptor is evaluated according to their resilience and value;
- Impacts that could potentially affect receptors are identified and their nature described. The magnitude of potential impacts (negligible, low, moderate or high) resulting as a consequence of the Project is assessed. Measures that have been incorporated into the Project design to minimise or avoid impacts are described and are taken into account in the impact assessment;
• The likely significance (not significant, low, moderate or high) of these impacts on receptors are then assessed, and where possible quantified;
• Mitigation measures to avoid or reduce any moderate or high significance impacts are then described in conjunction with other elements of the design (including mitigation for other environmental disciplines). If necessary, specific measures to compensate for effects on features of nature conservation importance are identified;
• Mitigation measures for impacts to features which result in IFC critical habitat status are presented with the aim of leading to a gain in biodiversity; and
• The significance of potential residual effects is assessed.

11.6.1 Impact Assessment Criteria

The construction of the Project involves a wide range of activities that have the potential to affect the terrestrial environment, primarily during the Construction Phase. The relevant activities of the Project likely to give rise to impacts on receptors are summarised in Table 11.20.

11.6.2 Defining Receptor Sensitivity

As noted in Chapter 3 Impact Assessment Methodology, receptor sensitivity is a combination of receptor ‘resilience’ (i.e. its vulnerability) and its ‘value’. There are no universal and standardised methodologies for assigning resilience and value to ecological receptors. This is partly due to the very large number of factors that can influence any assessment. Within this chapter, the sensitivity of habitats and species has been assessed using surrogate measures of sensitivity that combine elements of both resilience and value.

For species, sensitivity has been defined according to conservation status within the IUCN RL, RDB RF and RDB KK. This is based on the assumption that a species with increased extinction risk is likely to have inherently lower resilience to a range of stressors. This is not an assessment of resilience to Project specific impacts, as these are considered within the impact assessment itself. The level of rarity of a species is a significant part of the assessment of extinction risk. Rarity is also a key factor in assigning value to a species, as partially demonstrated by its degree of protection through legal instruments, either at international, national or regional levels. This is the case in Russia, where wildlife protection legislation is driven by RDB status, either at local or national level. Table 11.22 presents the derived scale of species sensitivity.

Habitat sensitivity has been defined on the level of naturalness of a particular habitat (Table 11.21). This is based on the general relationship between naturalness and value, with natural pristine habitats valued higher than modified and artificial habitats. It can also be argued that natural habitats are less resilient than artificial habitats as they are often easier to damage and harder to restore than habitats that are already modified to some extent. This is reflected within IFC PS6 which distinguishes between natural and modified habitats. It is also partially reflected by protective legislation, which tends to apply to areas of natural habitat.

The concept of ‘critical habitat’ according to the IFC PS6 is not incorporated as a separate element into the determination of habitat sensitivity. This is due to the definition of critical habitat deriving from a number of different criteria that depend on both species and habitat criteria which do not fully align with the hierarchy of ‘high, moderate and low’ sensitivity used within this chapter. The definition of critical habitat and compliance with IFC PS6 is therefore considered as a separate, but parallel, procedure. A separate critical habitat assessment has been undertaken and is presented in Appendix 11.1. Notwithstanding this, where relevant, individual receptors are identified as being component of critical habitat within the chapter. Impacts on such receptors are also highlighted in relation to IFC PS6. For such receptors, mitigation proposals have been formulated in the context of IFC PS6 requirements. The chapter also presents a summary that demonstrates to what extent IFC PS6 requirements are complied with, following the implementation of appropriate mitigation measures.

11.6.3 Defining Impact Magnitude

The key potential impacts associated with the Project that have been considered in this chapter are:

- Direct land take, temporary (during Construction Phase) and permanent (during Construction and Operational Phases), resulting in loss or fragmentation of habitats;
- Direct impacts on protected species;
- Indirect noise, vibration and visual disturbance;
- Changes in air quality due to dust generation, site plant emissions and road traffic;
- Changes in hydrology due to changes in drainage regime;
- Increased risk of pollution; and
- Changes in floristic assemblages following completion of construction.

The frameworks for defining the magnitude of impacts on habitats and species are presented in Table 11.23 and Table 11.24 respectively.
Table 11.23 Impact Magnitude - Habitats

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High (4)</td>
<td>The impact has the potential to adversely affect the integrity of an area/region, by substantially changing in the long term its ecological features, structures and functions, across its whole area, that enable it to sustain the habitat, complex of habitats and/or population levels of species that makes it important.</td>
</tr>
<tr>
<td>Moderate (3)</td>
<td>The area/region’s integrity is predicted to not be adversely affected in the long term, but the project is likely to affect some, if not all, of the area’s ecological features, structures and functions in the short or medium term. The area/region may be able to recover through natural regeneration and restoration.</td>
</tr>
<tr>
<td>Low (2)</td>
<td>Neither of the above applies, but some minor impacts of limited extent, or to some elements of the area, are evident but easy to recover through natural regeneration.</td>
</tr>
<tr>
<td>Negligible (1)</td>
<td>Indiscernible from natural variability.</td>
</tr>
</tbody>
</table>

Table 11.24 Impact Magnitude – Species

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High (4)</td>
<td>Impact on a species that affects an entire population to cause a decline in abundance and/or change in distribution beyond which natural recruitment (reproduction, immigration from unaffected areas) would not return that population or species, or any population or species dependent upon it, to its former level within several generations6, or when there is no possibility of recovery.</td>
</tr>
<tr>
<td>Moderate (3)</td>
<td>Impact affects a portion of a population and may bring about a change in abundance and/or a reduction in the distribution over one or more generations*, but does not threaten the long-term integrity of that population or any population dependent on it. The size and cumulative character of the consequence is also important. A moderate magnitude impact multiplied over a wide area would be regarded as a high magnitude impact.</td>
</tr>
<tr>
<td>Low (2)</td>
<td>A low magnitude impact on a species affects a specific group of localized individuals within a population over a short time period (one generation or less), but does not affect other trophic levels or the population itself.</td>
</tr>
<tr>
<td>Negligible (1)</td>
<td>Indiscernible from natural variability.</td>
</tr>
</tbody>
</table>

---

6 These are generations of the animal / plant species under consideration not human generations
### 11.6.4 Determining Impact Significance

As outlined in **Chapter 3 Impact Assessment Methodology** of this ESIA Report, the significance of an impact on a receptor is determined as a relationship between the sensitivity of the receptor and the magnitude of the predicted impact. The relationship between receptor sensitivity and impact magnitude, along with the resultant significance of an impact (beneficial or adverse) is presented in Table 11.25 below.

#### Table 11.25 Impacts Significance Matrix

### 11.6.5 Applicable Standards

The terrestrial ecology assessment has considered relevant Russian federal (national) and regional legislation, applicable standards and guidelines for international finance, and international agreements to which the Russian Federation is a signatory. All applicable standards relevant to the ESIA are presented in **Chapter 2 Policy, Regulatory, and Administrative Framework**, with those of particular relevance to ecology and biodiversity summarised below.

#### Federal and Regional Legislation

Table 11.26 presents the federal laws of the Russian Federation which are applicable to biodiversity and conservation.
Table 11.26 Russian Federal Legislation Relevant to Biodiversity and Conservation

<table>
<thead>
<tr>
<th>Legislation</th>
<th>Date and Reference Number</th>
<th>Relevance to Project</th>
</tr>
</thead>
<tbody>
<tr>
<td>Federal Law ‘On Environmental Protection’ (Ref. 11.24)</td>
<td>10.01.2002, No. 7-FZ</td>
<td>This is the overarching law on environmental protection. This law states that an environmental review will be undertaken to verify that Project documentation complies with environmental requirements set by the technical regulations and environmental legislation preventing activities that could cause adverse environmental impact.</td>
</tr>
<tr>
<td>Federal Law ‘On Wildlife’ (Ref. 11.7)</td>
<td>24.04.1995, no. 52-FZ</td>
<td>This law regulates wildlife protection, as well as, conservation and restoration of wild habitats. It promotes the conservation of biodiversity, sustainable use of all the wildlife components, creation of conditions for sustainable livelihood, conservation of generic resources of wild animals and other protection of wildlife as an integral element of the natural environment.</td>
</tr>
<tr>
<td>Federal Law ‘On Specially Protected Natural Areas’ (Ref. 11.25)</td>
<td>14.03.1995, no. 33-FZ</td>
<td>This law establishes a system of specially protected natural areas, specifies conditions of their use and protection of natural resources. The protected area ‘Utrish’ is located approximately 4 km south-east of the landfall and offshore section of the Project.</td>
</tr>
<tr>
<td>Forest Code of the Russian Federation (Ref. 11.13)</td>
<td>04.12.2006, No. 200-FZ</td>
<td>The Forest Code establishes the regulatory basis of efficient use, protection, security and reproduction of forests, as well as increasing their environmental and resource potential.</td>
</tr>
</tbody>
</table>

Other national legislation relevant to biodiversity and the ESIA includes:

- Government Enactment ‘On the Red Data Book of the Russian Federation’ (Ref. 11.26);
- Government Enactment ‘On measures for enforcement of obligations arising from the Conservation on the Wetlands of International Importance (Especially as Wildlife Habitats dated 02.02.1971)’ (No. 1050 of 13.09.1994) (Ref. 11.27);
- Government Enactment ‘On the adoption of requirements for the prevention of wildlife loss’ (No.997 of 13.08.1996) (Ref. 11.28) This enactment sets out requirements to regulate operating activities in order to manage and prevent loss of wildlife species and habitats (as a result of changing habitat and migration paths). It covers: water intake facilities; production equipment units; mobile transport and agricultural machines; construction of production and other facilities; extraction, processing and transportation of raw materials; and technological processes of cattle breeding and plant growing; and
- Order ‘On the adoption of rules of using forests for construction, upgrade and operation of line facilities’ (Ref. 11.29).
The ESIA takes account of Krasnodar regional legislation, including Krasnodar Region Laws such as the Decree of the Head of the Administration for Krasnodar Krai, ‘On the Red Data Book of Krasnodar Krai’, dated 21.12.2010 No.1202 (Ref. 11.30) which outlines protection principles for the Red Data Book of Krasnodar Krai, as well as, its contents, the procedure for keeping records and the protection categories of the listed species.

**International Financial Institution standards and guidance**

The Project is undertaken in accordance with the standards and guidelines of relevant International Financial Institutions, including the IFC Performance Standards (PS) (Ref. 11.11), Equator Principles (Ref. 11.31) and OECD Common Approaches (Ref. 11.32). However the IFC PS, including IFC PS6 Biodiversity Conservation and Sustainable Management of Living Natural Resources, sets out an approach to protect and conserve biodiversity including habitats, species and communities, ecosystem diversity, and genes and genomes, all of which have potential social, economic, cultural and scientific importance. It also sets out definitions of natural, modified and critical habitat types, stating that there should be no net loss of biodiversity in natural habitats. In critical habitat, mitigation measures should result in a net gain of those biodiversity values for which the critical habitat was designated. Such measures should be described in a Biodiversity Action Plan (BAP).

**International Agreements**

The Russian Federation is a signatory of the following conventions of relevance to biodiversity and conservation:

- **Convention on Biological Diversity, 1992** (Ref. 11.33) - The Convention promotes conservation of biological diversity and sustainable use of its components, and the Project Pipeline corridor and temporary facilities will affect habitats; and  
- **Convention on Wetlands of International Importance, especially as Waterfowl Habitat (Ramsar), 1971** (Ref. 11.34) - The Ramsar Convention promotes the importance of the ecological functions of wetlands, and the Project onshore facilities may impact on wetlands.

### 11.6.6 Ecology Receptor Identification and Sensitivity

The section below identifies the receptors within the Wider Study Area to be included in the impact assessment and discusses their sensitivity in line with the criteria presented in Section 11.6.2 above.

#### 11.6.6.1 Designated Sites

**Utrish SPNA**

Utrish is a statutory protected site which is designated for its conservation and biodiversity value. The site is known to contain a wide range of red list species and habitats which are notable at the regional, national, and international level. It is also considered to be of particular importance to Nikolski’s tortoise. The site is therefore assessed as being of high sensitivity.
Protective Forest Areas

The areas designated as ‘protective forest’ include areas of shiblyak woodland, mesophilic forest, and juniper woodland. These areas of habitat have been assigned sensitivity individually in Table 11.27 below.

11.6.6.2 Habitats and Flora

Habitats

Table 11.27 describes each habitat type in relation to the criteria used to determine sensitivity for habitats.

| Coastal shingle                   | Designation  
This habitat type receives no formal designation or statutory protection.  
Naturalness  
The habitat is largely natural with relatively little evidence of artificial disturbance or anthropogenic transformation.  
Sensitivity  
This habitat is assessed as being of moderate sensitivity. |
| Urban and agricultural habitats    | Designation  
This habitat type receives no formal designation or statutory protection.  
Naturalness  
These habitats have been altered through human activity and are considered to be significantly altered from their original state.  
Sensitivity  
This habitat is assessed as being of negligible sensitivity. |
| Running Water                     | Designation  
This habitat type receives no formal designation or statutory protection.  
Naturalness  
The habitat is largely natural with relatively little evidence of artificial disturbance or anthropogenic transformation.  
Sensitivity  
This habitat is assessed as being of moderate sensitivity. |

Urban and agricultural habitats are assessed as being of negligible sensitivity. These habitats are therefore considered to be of insufficient ecological value to warrant further consideration in the impact assessment. These habitat types are therefore not discussed further within this assessment.

**Flora**

The species listed below have been recorded within the Study Area during field survey (Table 11.28).

### Fauna

#### Invertebrates

A notable assemblage of red list invertebrate species is potentially present within the Study Area. This includes 10 species likely to occur within the mesophilic forest, 20 within the areas of meadow habitat and one near riparian and aquatic environments (Table 11.28 above and Table 11.29 below for further detail).

Fish

None of the fish present within the Study Area are listed as species of conservation concern on the IUCN RL, RDB RF, or RDB KK. Individuals and the freshwater fish assemblage present within the Study Area are therefore assessed as being of negligible sensitivity and are considered to be of insufficient ecological value to warrant further consideration in the impact assessment.

Birds

**Breeding Birds**

Seven of the bird species that are considered to have bred within the Study Area are red list species (Table 11.31). In addition, a further five species are listed on appendix 3 of the RDBKK, which are species that are recommended for further research in the region. The sensitivity of the latter species are not assessed individually, but included as part of the breeding bird assemblage. The combined breeding bird assemblage largely consists of a wide range of common and ubiquitous species which are typical for the habitats present in the Project Area. This combined assemblage is assessed as being of low sensitivity.

**Non-breeding Migratory and Overwintering Birds**

Five non-breeding migrants of conservation concern were recorded flying over the Study Area; however, the Project Area does not contain habitats that would support significant aggregations of red list migratory bird species. In addition, the Project Area is not identified as a bottleneck migration site or a significant stop over site. It is not anticipated that the Project will result in a direct or indirect impact on migratory bird species of ecological importance and these are not considered further in this assessment.

The wintering bird assemblage supported by the terrestrial habitats of the Study Area consists of widespread and ubiquitous species of passerine birds. The terrestrial habitats of the Study Area does not offer suitable foraging or nesting opportunities for large aggregations of wintering birds and therefore impacts on wintering bird species within the Study Area are not considered further.

11.6.7  Assessment of Potential Impacts: Design and Development

Geotechnical surveys were undertaken in 2012 to inform the design and layout of the Project. Some geotechnical surveys were undertaken along a section of the sea cliff, located to the west of the proposed microtunnel entry shafts. The surveys were undertaken in compliance with Russian regulations.

To facilitate the geotechnical surveys, four strips, each approximately 4 m wide and 120 m long, were cleared of vegetation from the top of the cliff, down the western face and to the shoreline. Various access roads and drill pads were also constructed to facilitate access for the geotechnical surveys.
The drill pads and their associated access roads were constructed within areas of shiblyak (largely within the drill pad access road areas), juniper woodland and tomillyar habitats (located along the top of the cliff).

The impact of the site preparation works for the design and development works resulted in loss of natural terrestrial habitat along the cliff tops as well as down the cliff itself. Additional habitats were removed to accommodate the drill pads and associated roads. The total area of habitat lost was approximately 0.39 ha of shiblyak, 0.03 ha of tomillyar and 0.32 ha of juniper woodland. In addition to the loss of habitat, the access track is being used by people to access the area. During a site visit made in September 2013, signs of fly tipping and fire lighting were evident. Increased access could also lead to increased disturbance of threatened species.

It was agreed with the Forestry Department that the main access track up to the cliff top will not be reinstated as this track will be used by the Forestry Department for forestry maintenance works. Due to the presence of habitats of a moderate sensitivity, and presence of flora species of up to high sensitivity (including fern-leaved speedwell and *Rindera tetrapsis*), the impact within this area could be of up to high adverse significance in the absence of any mitigation or successful reinstatement of lost or damaged habitats.

In order to mitigate for these impacts, a re-instatement plan has been devised to mitigate for the impact of the geotechnical works. This mitigation has been incorporated in to a Cliff Area Habitat Reinstatement Plan which is included in Appendix 11.2. All works stipulated in this plan will be completed by the client and the works will result in the re-establishment of a significant proportion of the original habitats, both through planting and natural re-colonisation. The Cliff Area Habitat Reinstatement Plan will be implemented as part of the BAP.

As tomillyar, fern-leaved speedwell and *Rindera tetrapsis* confer critical habitat status, a BAP will be developed to deliver net gains in these biodiversity features. The BAP will provide a robust long-term biodiversity monitoring and evaluation programme as well as engagement with relevant stakeholders.

Taking into consideration the planned reinstatement works and monitoring plan (refer to Appendix 11.2) it is likely that the residual impacts of the design and development works within the cliff area will be of no more than **Low** adverse significance. Any impact on tomillyar or the populations of fern-leaved speedwell and *Rindera tetrapsis* would constitute an effect on critical habitat (see Appendix 11.1). However, following implementation of the Cliff Area Habitat Reinstatement Plan, it is considered that there would be no net loss of these components.

### 11.6.8 Assessment of Potential Impacts: Construction and Pre-Commissioning

This section presents and discusses the impacts and mitigation measures of the Construction and Pre-Commissioning Phase of the Project on the identified terrestrial ecology receptors within the Study Area (see Section 11.6.6). The Project has been designed to reduce a number of impacts at source. Design measures have been incorporated to reduce the potential impacts from a given Project activity. Potential Construction and Pre-Commissioning Phase impacts are assessed on this basis. Additional mitigation and monitoring measures are then identified that can further reduce impacts, and the residual impact is identified.
Design measures are presented in Chapter 5 Project Description. Those of particular relevance to terrestrial ecology include the following:

- Microtunnelling below the Shingar River;
- Drainage to manage surface run-off, which will be constructed along access roads and at the landfall facilities;
- The use of geotextiles in the construction of permanent and temporary access roads;
- Stripping and stockpiling topsoil (stockpiles will normally be less than 2 m in height) for later use during reinstatement;
- Backfilling of trenches, which will normally occur immediately after the Pipeline has been lowered;
- Reinstatement of the Pipeline corridor, which will include restoration of original land contours as closely as possible, except grading of slopes at the Graphova Gap to manage slope stability;
- Dedicated mobile plant and refuelling areas. Fuel storage tanks will be double-walled. Secondary containment by bunding will surround the tanks;
- Provision of wastewater collection systems and offsite disposal by licensed waste management operators; and
- Chemical storage areas, which will be constructed on hard standing with bunding.

11.6.8.1 Designated Sites

Project activities have the potential to affect designated sites directly (through land-take, whether temporary or permanent) and / or indirectly (through degradation due to changes in air quality, introduction of pollutants (aerial or otherwise), invasive species and potentially damage due to fire).

Utrish SPNA

Utrish SPNA is located approximately 3.8 km to the south of the landfall section. Land-take within the SPNA will therefore not occur. Due to the distance between the site and construction activities, damage or degradation to the SPNA due to dust is not anticipated. The potential for NOx and SO2 to degrade the habitats contained within the Utrish (predominantly the forest habitats) has been considered. Air quality modelling has determined that, during the course of construction, the change in the atmospheric concentrations of NOx and SO2 within the vicinity of the SPNA will be minimal (a change of less than approximately two percent, when compared to the relevant criteria / standards) (see Chapter 9 Air Quality). Furthermore, considering that the impact will last only for the duration of construction (approximately 1 year), and will cease following completion of construction, changes in NOx and SO2 concentrations are unlikely to affect the habitats contained within the Utrish SPNA. In the absence of mitigation, the impact is assessed as being of negligible magnitude resulting in a Not Significant effect.

In the absence of appropriate controls, there is the potential for the introduction of invasive fauna and flora during construction. Invasive species have the potential to significantly alter the
ecology of the SPNA and affect its overall integrity in the long term. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of high sensitivity resulting in an effect of **High** significance.

**Protective Forests**

The assessment for the areas of habitat within the Study Area designated as ‘protective forest’ are considered in the relevant habitat sections below (see assessments for shiblyak, mesophilic forest and juniper woodland).

### 11.6.8.2 Habitats and Flora

**Habitats**

Direct impacts due to landtake will occur within the juniper woodland, mesophilic forest, shiblyak, and secondary steppefied meadow all of which fall within the Project’s construction corridor. Table 11.33 presents the area of each habitat that will be removed during construction.

In addition to the above, there is the potential for indirect effects due to changes in air quality, introduction of pollutants (aerial or otherwise) and invasive species.

**Table 11.33 Direct Habitat loss within the Study Area**

<td>0</td>
</tr>
</tbody>
</table>

**Juniper Woodland**

Approximately 2.6 ha of juniper woodland will be cleared during construction. Approximately 1.9 ha of this loss will be permanent due to the requirement for a permanent RoW along the Pipeline route. The remaining 0.7 ha has the potential to be reinstated post-construction
although the habitat would be likely to only return to its pre-clearance state in the long term (20 years or more).

The loss of 2.6 ha constitutes approximately 4.6 percent of the juniper woodland within the Study Area. The loss of this woodland is unlikely to affect the ability of this habitat type to persist within the region. The impact is assessed as being of a moderate adverse magnitude on a receptor of moderate sensitivity resulting in Moderate significance effect.

There is the potential for degradation to juniper woodland (which has not already been affected by land take) due to dust and adverse changes in air quality. The impact on vegetation will be temporary (lasting for approximately one year) and for this reason is unlikely to alter the structure or composition of affected juniper woodland in the long term (see Chapter 9 Air Quality). The impact is assessed as a low magnitude impact resulting in an effect of Low significance.

There is the potential for the introduction of invasive fauna and/or flora during construction. Invasive species have the potential to significantly alter the ecology of juniper woodland and affect its overall integrity in the long term. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of moderate sensitivity resulting in an effect of High significance.

**Mesophilic Forest**

Approximately 1.4 ha of mesophilic forest will be cleared during construction. Approximately 0.8 ha of this loss will be permanent while the remaining 0.7 ha has the potential to be reinstated post-construction. As with juniper woodland, this would likely only occur in the long term. The loss of this habitat is also likely to fragment remaining mesophilic woodland habitat to the north and south within the Graphova Gap.

The proportion of mesophilic forest directly affected is approximately 2.2 percent of this habitat type recorded within the Study Area. The loss of a relatively small proportion of this woodland is unlikely to affect the ability of this habitat type to persist within the region.

In the absence of mitigation, the impact is assessed as being of a moderate adverse magnitude on a receptor of moderate sensitivity resulting in an effect of Moderate significance.

There is the potential for degradation to mesophilic woodland (which has not already been affected by land take) due to dust and adverse changes in air quality. The impact on vegetation will be temporary (lasting for approximately one year) and for this reason is unlikely to alter the structure or composition of affected mesophilic forest in the long term (see Chapter 9 Air Quality). The impact is assessed as a low magnitude impact resulting in an effect of Low significance.

There is the potential for the introduction of invasive fauna and/or flora during construction. Invasive species have the potential to significantly alter the ecology of mesophilic forest and affect its overall integrity in the long term. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of moderate sensitivity resulting in an effect of High significance.
The impact on mesophilic forest constitutes an effect on critical habitat (see Appendix 11.1)

**Shiblyak**

Approximately 3.5 ha of shiblyak will be cleared during construction. Approximately 2.4 ha of this loss will be permanent due to the requirement for a permanent RoW. The remaining 1.1 ha has the potential to be reinstated post-construction although, as with juniper woodland, the habitat would only return to its pre-clearance state in the long term.

The proportion of shiblyak directly affected is approximately 0.8 percent of the habitat type recorded within the Study Area. The relatively small loss of this woodland is unlikely to affect the ability of this habitat type to persist within the region. In the absence of mitigation, the impact is assessed as being of a moderate adverse magnitude on a receptor of moderate sensitivity resulting in an effect of *Moderate* significance.

There is the potential for degradation to shiblyak (which has not already been affected by land take) due to dust and adverse changes in air quality. The impact on vegetation will be temporary (lasting for approximately one year) and for this reason is unlikely to alter the structure or composition of affected shiblyak in the long term (see *Chapter 9 Air Quality*). The impact is assessed as a low magnitude impact resulting in an effect of *Low* significance.

There is the potential for the introduction of invasive fauna and/or flora during construction. Invasive species have the potential to significantly alter the ecology of shiblyak and affect its overall integrity in the long term. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of moderate sensitivity resulting in an effect of *High* significance.

**Secondary Steppefied Meadow**

Approximately 4.1 ha of secondary steppefied meadow will be cleared during construction. This includes permanent habitat loss along the Pipeline RoW, and temporary loss associated with the construction of the temporary access roads. There is therefore the potential for the majority of this habitat to be reinstated and a large proportion of the loss (up to 90% of the cleared habitat) is therefore considered to be in the short term (within 1 – 2 years following completion of construction).

The loss of approximately 3.7 percent of the habitat within the Study Area is therefore assessed as being an impact of low adverse magnitude on a receptor of low sensitivity. This equates to an effect of *Low* significance.

There is the potential for degradation to other habitats due to dust and adverse changes in air quality. The impact on vegetation will be temporary (lasting only for the duration of construction). It is therefore unlikely that the structure or composition of these habitats will be affected in the long term. The impact is assessed as a low magnitude impact resulting in an effect of *Low* adverse significance.

There is the potential for the introduction of invasive fauna and/or flora during construction. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of low sensitivity resulting in an effect of moderate significance.
Tomillyar and Mesophilic Meadow

There is the potential for degradation to other habitats due to dust and adverse changes in air quality. The impact on vegetation will be temporary (lasting only for the duration of construction). It is therefore unlikely that the structure or composition of these habitats will be affected in the long term. The impact is assessed as a low magnitude impact resulting in an effect of Low adverse significance.

There is the potential for the introduction of invasive fauna and / or fauna during construction. Although of a relatively low probability, it is potentially a high magnitude impact on a receptor of moderate sensitivity resulting in an effect of High significance.

Running Water

The Pipeline crosses two watercourses (the Shingar River and an unnamed tributary of the Sukko) on one occasion each (please see Figure 11.7 for further detail). The effect of the Project on the soils and hydrological regime of these watercourses is discussed in Chapter 8 Soil, Groundwater and Surface Water.

The Shingar River will be crossed with the use of micro-tunnelling (see Chapter 5 Project Description) and impacts to this watercourse during its crossing are therefore anticipated to be limited. However, there is the potential for other construction activities within the RoW and at the microtunnel construction site to cause runoff and increased sediment to enter the watercourse. The impacts associated with construction in the catchments of the Shingar River are likely to be medium term and of moderate magnitude and Moderate significance prior to mitigation.

With regards the crossing of the unnamed tributary in the Graphova Gap, open cut trenching is proposed at this location. Open cut trenching across the river will temporarily alter the flow during the works at the crossing and potentially result in flows during a flood event being diverted onto the surrounding floodplain. Given the nature of the topography at the crossing site with relatively steep valley sides, the impacts on the flow regime are likely to be local to the crossing. The crossing may also affect the sediment load and quality of the water at the crossing and along the downstream stretch of the watercourse. It is anticipated that the construction be undertaken in the low rainfall season when there is little to no flow in the ephemeral watercourse, which will reduce the likelihood of impacts. However, based on the worst case assumption that there are flows in the watercourse due to rainfall at the time of crossing construction, the impacts on the tributary in the Graphova Gap are medium term and is of moderate magnitude and Moderate significance (see Chapter 8 Soils, Groundwater and Surface Water).

The proposed Gazprom Invest permanent access road route crosses the Graphova Gap. Depending on the timing of the construction works, there could be impacts on the surfacewater flow regime, water quality and the hydromorphology of the river channel. Construction details are not currently available; however, construction of the stream crossing could temporarily alter the flow route during the works and potentially result in flood flows being diverted onto the surrounding floodplain. Given the nature of the topography at the crossing site with relatively steep valley sides, the impacts on the flow regime are likely to be local to the crossing. The
crossing may also affect the sediment load and quality of the river at the crossing and along the downstream stretch of the watercourse. The impacts of the construction works will be temporary and the watercourse will recover through natural processes. It is recommended that the construction be undertaken in low rainfall season when there is little to no flow in the ephemeral watercourse. Based on the worst case assumption that there are flows in the watercourse due to rainfall at the time of crossing construction, the impact on the tributary in the Graphova Gap is medium term and is of moderate magnitude and Moderate significance.

**Flora**

There is the potential for the direct loss and damage of flora of ecological value during the Construction Phase of the Project. There is also potential for indirect effects on flora located adjacent to the construction corridor due to dust and other construction related emissions.

Of the 26 notable plant species recorded within the Study Area, four have been recorded within the Pipeline construction corridor: Greek juniper, stinking juniper, pyramidal orchid and Kavakh peony. These species have the potential to be directly affected during construction.

*Greek and Stinking Juniper*

Greek and stinking juniper have been recorded within the juniper woodland and shiblyak habitats that will be directly affected during construction. Approximately 2.6 ha of juniper woodland and 3.5 ha of shiblyak will be cleared, resulting in the loss of specimens within these areas.

As is discussed above, the proportion of juniper woodland and shiblyak habitat lost is approximately 4.6 percent and 0.8 percent of each resource within the Study Area, respectively. The loss of this amount of habitat is not considered of sufficient magnitude to significantly affect the persistence of these species within the local area (within the Wider Study Area).

Construction is therefore expected to have a localised direct long term impact on Greek and stinking juniper. This is assessed as an impact of moderate adverse magnitude on a receptor of moderate sensitivity resulting in an effect of Moderate significance.

There is potential for dust and adverse changes in air quality to damage or degrade Greek and stinking juniper (see Chapter 9 Air Quality). Based on the temporary nature of construction activities (approximately 1 year), it is not anticipated that dust and air quality impacts would significantly affect the ability of these species to persist within the affected habitats. The degraded habitats would also be likely to recover to their original state in the short term (1 - 2 years) following cessation of the impact. It is assessed as an impact of low adverse magnitude on receptors of moderate sensitivity resulting in an effect of Low significance.

*Pyramidal Orchid, Campanula komorovii, Salvia ringens, and Linum hirsutum*

Four RDB plant species have been recorded in meadow habitats either within or in close proximity to the construction area for the Varvarovka bypass road. Clearance of this habitat during construction could therefore result in the loss of individuals or possibly a sub-population of these species within the construction area. As discussed above, approximately 4.1 ha of secondary steppefied meadow will be temporarily lost during construction; approximately 3.7
percent of the resource within the Study Area. The loss of this amount of habitat is not considered of sufficient magnitude to significantly affect the persistence of this species within the local area (within approximately 15 km of the Pipeline).

In the absence of mitigation, construction is therefore expected to have a localised, direct impact on these species. The impact is however considered reversible within the short – medium term (2 – 3 years) as the secondary steppefied meadow habitats are reinstated. The impact is therefore assessed as being of up to moderate adverse magnitude on receptors of moderate sensitivity resulting in an effect of Moderate significance.

The species may also be affected by dust and changes in air quality (discussed above for Greek and stinking juniper). The impact is assessed as an impact of low adverse magnitude on receptors of moderate sensitivity resulting in an effect of Low significance.

**Kavakh Peony**

Kalakh peony was recorded within the mesophilic forest within the construction corridor of the Pipeline. Clearance of this habitat during construction will result in the loss of all specimens within the construction corridor.

The proportion of mesophilic forest which will be cleared is approximately 2.2 percent of the resource within the Study Area. The loss of this amount of habitat is not considered of sufficient magnitude to significantly affect the persistence of this species within the local area (within approximately 15 km of the Pipeline).

Construction is therefore expected to have a localised direct long term impact on Kavakh peony. This is assessed as an impact of moderate adverse magnitude on a receptor of moderate sensitivity resulting in an effect of Moderate significance.

The species may also be affected by dust and changes in air quality (discussed above for Greek and stinking juniper). The impact is assessed as an impact of low adverse magnitude on receptors of moderate sensitivity resulting in an effect of Low significance.

**All Other Notable Flora**

No other notable plant species were recorded within the construction corridor and they are therefore considered to be either absent from the zone of direct impact of the Project or present in very low numbers. It is therefore very unlikely that the Project would affect the integrity of the local population of these species.

Therefore, as a worst case assessment, construction could potentially have direct and long term impact on a small population of these species. This is assessed as an impact of low adverse magnitude on receptors of low to moderate sensitivity resulting in an effect of no more than Moderate significance.

These species may also be affected by dust and changes in air quality (discussed above for Greek and stinking juniper). The impact is assessed as an impact of low adverse magnitude on receptors of up to moderate sensitivity resulting in an effect of Low significance.
Any impact on fern-leaved speedwell and *Rindira tetraspis* would constitute an effect on critical habitat (see Appendix 11.1). However neither species have been recorded within the construction corridor. Both species appear to be restricted to the coastal cliffs which will be micro-tunneled and therefore no impacts to either species would occur.

### 11.6.8.3 Fauna

**Invertebrates**

The potential impact pathways to invertebrates may be direct or indirect. Direct impacts may occur due to loss and fragmentation of habitats, as well as changes in the character of habitats. Indirect impacts may occur due to a decrease in floral species diversity resulting in a decrease in food availability, light pollution from construction works or changes in air quality.

Invertebrates of ecological importance are potentially relatively abundant within the Study Area, comprising beetles (nine species), weevils (one species), moths and butterflies (14 species), bees and wasps (two species), leaf hoppers, flies (one species), crickets (one species), mantids (one species) and dragonflies (one species). The majority of these species are most likely to be found within areas of meadow and woodland habitats (including the steppefied and mesophilic meadow, mesophilic forest, juniper woodland, and shiblyak).

The loss of relatively small proportions of suitable invertebrate habitat contained within the Study Area (mesophilic forest (2.2 percent), shiblyak (0.9 percent), steppefied meadow (4.1 percent), juniper woods (4.6 percent) and no loss from within the mesophilic meadow, tomillyar, coastal shingle or residential / ruderal habitats) will be partially mitigated by the availability of similar habitat adjacent to the Pipeline route where land take will occur.

Degradation to adjacent habitats may occur as a result of light, dust and emission of air pollutants during construction. If left unmitigated, this could potentially result in larger areas of suitable invertebrate habitat being affected. However, this impact would be of short duration (restricted to approximately one year).

Considering the relatively limited extent of habitat loss, availability of other suitable habitat within the local area, the impact on invertebrates is assessed as being of low adverse magnitude. The effect of construction on invertebrates is assessed as considered to be of up to Moderate significance, due to the sensitivity of the receptor (up to moderate) and magnitude of the impact (adverse moderate).

Any impact on Levantine skipper populations would constitute an effect on critical habitat (see Appendix 11.1). This species is associated with dry open grassland habitats. The loss of such habitat as a result of the Project is limited in extent and unlikely to adversely affect the population of this species. Due to the operational requirement for open habitats to replace lost woodland, the likely available habitat for this species will increase in extent as a result of the Project.
Herpetofauna

Potential impacts on reptiles during the Construction and Pre-Commissioning Phase include the loss and fragmentation of habitats, direct mortality or injury to individuals, disturbance to individuals during the breeding and hibernation period, and obstruction of movement.

Nikolski’s tortoise

**Habitat loss:** Works occurring during the species’ active period will affect areas of shiblyak (3.5 ha), juniper woodland (2.6 ha), mesophilic forest (1.4), and secondary steppefied meadow (4.1 ha); all of which are important to the tortoise for foraging, shelter and breeding. Areas of agricultural habitat which are less important, but are a potential foraging resource for the species, will also be cleared.

A proportion of this loss will be reversible, as the cleared habitats will be reinstated following completion of construction. However recovery of these habitats could take from 2-5 years (in the case of the steppefied secondary meadow and vineyard) to over 20 years (in the case of the woodland habitats) (see the Habitats assessment above for further detail).

**Disturbance impacts:** In addition to direct habitat loss during construction, tortoises could also be impacted through disturbance. A number of studies have recorded disturbance effects on tortoises from roads. Both Nafus et al., (2013) and Boarman and Sazaki, (2006) recorded declines in the apparent densities of tortoises within 400 m of roads; Nafus et al., (2013) reported a decline in tortoise signs of over 40% between low and medium/high traffic roads, although a large proportion of this may have been due to road kill (Ref. 11.21 and Ref. 11.22).

**Direct mortality impacts:** In the absence of mitigation, direct mortality to tortoises could occur due to plant or vehicle collisions, damage during trenching activities, harm by humans or introduced animals (e.g. dogs). Tortoises hibernating in the ground could be directly affected by works undertaken during the hibernation period.

**Habitat severance and fragmentation:** Construction of the Pipeline and of the access roads, could affect seasonal migrations of the tortoise (i.e. from the hill areas or open habitats (shiblyak and juniper woodland and meadow) to the valley floors within the mesophilic woodland). In particular, the route of the Pipeline crosses the Graphova Gap, fragmenting two significant areas of habitat located to the north and south. This would affect the species during the construction period (for approximately 24 months), with the impact within the Pipeline route ceasing on completion of construction.

The effect of habitat loss and fragmentation, as well as the potential for direct mortality and disturbance of tortoises, has the potential to affect not only the population of tortoises within the Study Area (currently estimated 150 - 350 individuals) (Ref. 11.14), but potentially may also affect the population beyond the Study Area due to the effects of reduced fecundity and population fragmentation. The Project therefore has the potential to affect the integrity of a
significant\(^7\) population of tortoises (150 – 350 individuals or approximately 2 - 5% of population of the Abrau peninsula).

In the absence of mitigation, the impacts arising at the Construction Phase therefore have the potential to affect the integrity of a globally significant population of a critically endangered species of tortoise in the medium – long term. The impact magnitude is assessed as being moderate adverse on a receptor of high sensitivity, resulting in an effect of **High** significance.

Any impact on Nikolski’s tortoise would constitute an effect on critical habitat (see Appendix 11.1).

**European Glass Lizard and Aescalupean Ratsnake**

European glass lizards were recorded at various locations within the Study Area and are considered a frequently occurring species. Aescalupean ratsnake was also recorded at various locations within the Study Area although at lower densities. The species is therefore considered either likely absent or present in relatively low numbers within the Study Area.

Both species forage, shelter, breed and hibernate within habitats that will be directly impacted during construction: including shiblyak, juniper woodland, mesophilic forest and steppefied secondary meadow. They are also potentially present foraging within the agricultural habitats although these areas are considered sub-optimal. When viewed within the context of the local area (within the Wider Study Area), the proportion of habitat lost and fragmented is not anticipated to be sufficient to significantly affect the ability of the local species populations to survive in the long term. It is also likely that the majority of habitat which will be directly affected during construction will be reinstated post-construction (see Habitats assessment above). The impact is therefore assessed as being of low adverse magnitude on a receptor of moderate sensitivity resulting in an effect of **Low** significance.

As discussed above, the construction of the Varvarovka bypass access road will occur when reptile species are potentially hibernating. There is the potential for both European glass lizard and Aescalupean ratsnake to be present within the open habitats (such as the secondary steppefied meadow). Therefore, habitat removal during the hibernation period could result in the direct mortality of a number of these species.

There is also the potential for the killing and injury of these species outside of the hibernation period (as discussed above for Nikolski’s tortoise). The deaths of individuals will reduce the size of the local population and potentially the pool of breeding adults. This could have a long term adverse impact on the local population of these species. The impact is assessed as being of up to moderate adverse magnitude resulting in an effect of **Moderate** significance.

There is some potential for construction activities to restrict the movement of these species. European glass lizards generally have a relatively limited range and the severance effect is unlikely to be of a magnitude which would affect the population within the Study Area.

\(^7\) Significant in this context refers to greater than 1% of a regionally important population (i.e. the Abrau peninsula population).
Construction related severance may restrict the movement of Aesculapean snake slightly, although it is unlikely to stop the species from accessing sufficient foraging, sheltering hibernation or breeding habitat within the Study Area. It will also only persist for the duration of the construction period. The impact is assessed as being of low magnitude resulting in an effect of **Low** significance.

**All Other Common Reptiles**

The effects on common reptiles are anticipated to be the same as for glass lizard and Aesculapean snake, discussed above. This includes habitat loss, killing of individuals (including during the hibernation period) and creation of barriers to the dispersal of species.

The Project is anticipated to have a medium term localised impact on terrestrial habitats used by reptiles during the Construction Phase, resulting in a temporary loss of habitat and biota along the alignment. It is assessed that this is a negative impact of low to moderate magnitude on species of low sensitivity resulting in an effect of up to **Moderate** significance.

**Amphibians**

Amphibians are potentially sheltering and foraging within habitats which will be directly impacted during construction, including the shiblyak, juniper woodland, mesophilic forest, secondary steppefied meadow and agricultural habitats. Suitable breeding habitat, adjacent to watercourses within the mesophilic forest, and within ephemeral waterbodies which are not location specific, are also likely to be subject to direct loss. This loss is not anticipated to be sufficient to significantly affect the ability of the local amphibian population to survive in the long term as sufficient habitat remains within the Study Area to support these species. The impact is therefore assessed as being of low adverse magnitude on a receptor of low to moderate sensitivity resulting in an effect of up to **Moderate** significance.

Construction activities also have the potential to kill and injure species potentially present within the aforementioned habitats (including during the hibernation period, as discussed above for reptiles). This has the potential to affect the amphibian population, including the RDB listed Caucasian toad, within the Study Area in the medium term. This impact is assessed as being of up to moderate magnitude, as it will affect the local amphibian population in the medium term. It is therefore assessed as an effect of **Moderate** significance.

Construction activities may restrict the movement of amphibians, particularly during the breeding season when these species need to access waterbodies for breeding. This has the potential to fragment and interrupt the breeding of the population of amphibians within the Study Area. This impact is likely to persist for only one breeding season as construction is predicted to last for 16 months. The impact is assessed as being of moderate magnitude resulting in an effect of up to **Moderate** significance.

**Birds**

Potential impacts on birds during the Construction Phase include the direct loss of breeding habitat. Breeding bird habitat with the potential to be directly affected during construction includes shiblyak (3.5 ha will be lost), juniper woodland (2.6 ha will be lost), mesophilic forest (1.4 ha will be lost), and steppefied secondary meadow (4.1 ha will be lost). There is also the
potential for individual birds which are nesting within these habitats to be killed or injured and for their nests to be damaged.

Breeding birds may also be affected by noise and visual disturbance from construction activity. Noise modelling has been undertaken at four locations to predict the likely noise levels associated with construction experienced at various locations within the Study Area (see Chapter 10 Noise and Vibration). The noise modelling predicts that within woodland, grassland, and vineyard areas close to the Pipeline route, during construction, noise levels will be experienced of between 39 - 59 dB depending on the activities being undertaken, compared to an ambient background levels of between 43 - 53.2 dB (noise modelling locations 9 to 12).

Short-toed Snake-eagle and Booted Eagle

Short-toed snake-eagle and booted eagle do not breed within areas of woodland which are likely to be directly or indirectly affected by the Project. Loss of potential breeding habitat, killing or injury of individuals, and damage to nests is therefore not anticipated.

Impacts on these species of raptor will therefore be limited to loss of suitable foraging habitat. Given the large amount of suitable hunting habitat for all species outside the Project area and as the population of breeding raptors is limited to one pair of each species this impact is considered to be of Low significance.

Wood Lark

Wood lark have been recorded breeding within the mesophilic woodland, steppefied secondary meadow, and agricultural habitats. Based on the population density surveys completed in 2011 the potential reduction in the number of wood lark in the Project Area is shown in Table 11.34.

Table 11.34 Potential Reduction in Breeding Pairs of Species of Ecological Importance as a Result of Habitat Loss

In addition to the loss of breeding habitat and potential for the killing or injury of individual wood lark, impacts will occur in a wider area due to increases in noise and visual disturbance so the 'loss' of breeding pairs is likely to be slightly higher. However, there are large areas of natural habitat that should be able to support some of these displaced breeding birds.
Therefore, the loss of 3 pairs is probably a reasonable estimate. The temporary loss of 3 breeding pairs would represent 1-1.5 percent of the total estimated breeding population of wood larks in the Krasnodar Krai (200-300 pairs), which would represent an impact of low magnitude. Post construction, the Pipeline route will be allowed to periodically re-vegetate (allowed to grow for 2 to 3 years and then cut). This area will therefore develop into a more open edge type habitat which is favoured by wood larks as well as many of the commoner breeding bird species breeding in the Project Area. In the long-term, this will allow all these species to breed in this area and it is therefore predicted that the Project will not result in a long-term decrease in breeding species.

In absence of mitigation, the impact on woodlark is therefore assessed as being of Moderate significance.

**Breeding Bird Assemblage**

As has been discussed above for the threatened breeding bird species, construction activities will result in the loss of potential breeding bird habitat, potential killing, injury and disturbance to individuals, potential damage to nests, and potential loss of foraging habitat. The proportion of habitat affected when compared to the amount of available habitat within the Study Area is unlikely to be sufficient to affect the ability of the breeding bird assemblage to breed and survive within the local area, either during construction or in the long term. The impact is therefore considered to be temporary and of a relatively low magnitude resulting in an impact of Low significance.

**Mammals**

Potential impacts on mammals during the Construction Phase include the loss and fragmentation of habitats and direct mortality or injury to individuals. Mammals may also be affected by noise and temporary lighting, which may result in disruption to foraging, breeding and migration.

**Bats**

Twelve species of bat are potentially present within the Study Area. This includes species assessed as being of low to moderate sensitivity.

Within the construction corridor, there are limited roosting opportunities for bats. Potential roost sites are restricted to 9 trees assessed as having low roost potential. These trees will be removed during construction and there is therefore potential for a small proportion of relatively low quality roosting habitat for bats to be lost. This is assessed as a low magnitude impact on a receptor of low to moderate sensitivity resulting in an effect of no more than Moderate significance.

There is potential for construction noise, vibration and construction related light pollution to disturb roosting bats (see Chapter 10 Noise and Vibration and 'Birds' Section above for further detail). This impact is likely to be restricted to works within the vicinity of the mesophilic woodland where potential roosting habitat exists. Construction activities within this area will be of a relatively short duration (approximately 1 year) and restricted in extent. Furthermore, other roosting habitat is available (including buildings and other trees) within the Study Area which
bats could use to roost. Temporary disturbance within areas of low roost potential is a low magnitude impact on a receptor of low to moderate sensitivity resulting in an effect of no more than **Moderate** significance.

In terms of foraging bats, habitats within the Study Area, including the woodland, meadow, rivers and agricultural habitats are likely to support foraging bats. The loss of these habitats and potential disturbance to foraging bats are unlikely to affect the ability of the local bat population to persist within the Study Area, as sufficient habitat of a similar quality remains. The impact is assessed as a low magnitude resulting in an effect of no more than **Moderate** significance.

Bats favour linear features such as rivers, forest edges and tree lines, which they use for navigation when commuting. The Graphova Gap which contains the unnamed tributary of the Sukko River flows is a potentially important commuting corridor for bats. Works within this area, if undertaken at night and during the bat activity season, have the potential to disturb bats commuting along this flight line. Light and noise disturbance are not anticipated to be of a scale which would result in the total severance of this route, although some disturbance to bats is possible. Low numbers of commuting bats have the potential to be temporarily disturbed although no commuting routes are likely to be completely severed during the Construction Phase. The impact is therefore assessed as a low magnitude impact of no more than **Moderate** significance.

**Other Mammals**

The following may be present both within the Study Area and along the Pipeline route: insectivores (confirmed sightings of hedgehog, Caucasian mole-rat, Caucasian common shrew); rodents (confirmed sightings of greater mole-rat, forest dormouse, field mouse); lagomorphs (sightings of brown hare and European rabbit); carnivores (including sightings of wolf, common jackal, red fox, common racoon, common marten, rock marten, and badger) and artiodactyls (including sightings of roe deer). Thus, construction of the Project has the potential to result in the loss of foraging and breeding habitat for these species, as well as to disturb them at various stages in their lifecycle (e.g. breeding and hibernation).

Construction will result in the loss of suitable foraging, sheltering, and breeding habitat for mammals. This includes areas of shiblyak, juniper woodland, mesophilic forest, secondary steppified meadow, and vineyard. When viewed within the context of the local area (within approximately 5 km of the Project), the proportion of habitat lost is not anticipated to be sufficient to affect the ability of mammals supported within the Study Area to survive. Habitat loss is therefore a low magnitude impact on receptors of low sensitivity resulting in an effect of **Low** significance.

There is the potential for killing and injury of individuals during construction (particularly the subterranean dwelling species such as mole-rats and smaller burrowing rodents). The other mammal species are have greater mobility and are likely to be able to quickly leave affected areas of habitat during the Construction Phase. In the absence of mitigation, construction activities could result in the deaths of relatively low numbers of mammals within the Study Area. The impact is potentially of moderate adverse magnitude resulting in an effect of **Low** significance.
Mammals are likely to be indirectly affected by noise (see Chapter 10 Noise and Vibration) and / or light disturbance during the Construction Phase. The impact is likely to be short term and reversible i.e. mammals will return to affected areas once construction ceases. This could affect a relatively small number of mammals within the vicinity of the construction corridor. It is assessed as an impact of low magnitude on a receptor of low sensitivity resulting in an effect of Low significance.

11.6.9 Mitigation and Monitoring: Construction and Pre-Commissioning

Where the likely impacts on ecological receptors are assessed to be of high or moderate significance, mitigation measures are proposed to lower the overall magnitude of impact on a particular receptor and to avoid or reduce significant impacts on habitats and protected species. Additional mitigation measures are required where there are potential impacts to component features of critical habitats so that the requirements of IFC PS6 are met.

The mitigation approach comprises a number of elements:

- General mitigation measures, including provision for an Ecological Clerk of Works (ECoW), training of construction personnel and implementation of a Construction Management Plan (CMP);
- Herpetile Mitigation Strategy that covers: firstly the construction period and details the measures to be undertaken to protect key ecological receptors such as the Nikolski’s tortoise, particularly during initial site clearance works (Appendix 11.3);
- A Habitat Reinstatement Plan (RP) (also referred to in the Projekt as the ‘Technical and Biological Recultivation Plan’) will provide detailed specifications for the restoration of habitats post-construction. Management and monitoring requirements for an appropriate length of time for each activity will also be specified; and
- A BAP will be developed to describe how the Project will meet IFC PS requirements for no net loss of biodiversity within natural habitats, and net gain requirements for components of critical habitat. Therefore, the BAP will provide a framework for a long-term biodiversity monitoring and evaluation programme. Development of the BAP will take into consideration relevant industry guidance, and will allow for adaptive management and consultation with stakeholders on topics of conservation related to the Projekt’s biodiversity interests.

The implementation of the management plans will be monitored by the Environmental and Social Monitoring Programme for the South Stream Offshore Pipeline.

11.6.9.1 General Mitigation Measures

Ecological Clerk of Works

A suitably qualified ECoW will be appointed by South Stream Transport, independent of the construction site contractor, for the duration of the onshore Construction Phase of the Project. The ECoW will be tasked with overseeing onshore construction activity and with ensuring that all mitigation measures are implemented in accordance with the CMP and associated documentation. Furthermore, the ECoW will be given the responsibility of compiling weekly /
monthly reports on issues such as non-compliance and on modification or supplementation of the CMP, and these reports will be submitted to South Stream Transport and to the construction contractor.

Due to the scale of the Project, the ECoW will be supported by specialists (e.g. botanists, zoologists) as necessary to assist with monitoring the implementation of the CMP and assisting with mitigation where necessary.

Site Personnel Training

Information on the ecological sensitivity of the habitats and species within the construction corridor will be included within a site induction package for all site personnel. This will ensure that all personnel working on site are aware of the sensitivities of the protected sites, habitats and species and are aware of the mitigation measures that need to be employed to minimise any adverse effects of the Project. These measures are described below in respect of terrestrial ecological receptors.

Construction Management Plan

A CMP will detail general mitigation measures to be applied for the Project during construction, and will include the following:

- Strict limitation of construction workers, materials and machinery to the defined construction areas to avoid impacts to surrounding habitats;
- Project workers will not be allowed to bring any live animals or plants into the construction site to avoid the risk of pest or invasive species establishing in the Project Area;
- Once quarries and disposal sites are confirmed by the contractor, South Stream Transport will conduct an invasive species risk assessment. If the findings indicate there is a significant risk of introducing alien invasive species then appropriate mitigation will be implemented. Such measures may include the washing or spraying of all incoming machinery at a demarcated ‘washing site’ to ensure that any mud or soil which may be carrying seeds is removed;
- The construction site will be monitored by the ECoW for the presence of alien invasive species. Where stands of alien invasive weeds that are known habitat transformers are found to occur within the construction site, such stands should be demarcated so that vehicles do not pass through these stands (and thus potentially spread seeds and other propagules of these species) and that the soils associated with these stands are not transported. An appropriate remediation strategy for alien invasive species will be implemented on-site, where these species are found to occur;
- In-line with GIIP, all construction sites will have appropriate sediment and erosion control practices applied. This will minimise the potential for seed dispersal and noxious weed establishment potentially associated with disturbance at construction areas and limit the likelihood of any effects on receptors remote from the immediate vicinity of the works;
- Storage areas shall only be placed in areas of low ecological importance (e.g. cultivated agricultural land);
• Project workers will be trained in litter / waste control procedures and fire emergency response procedures. This will aim to minimise the risk of accidental fires in surrounding vegetation. Suitable equipment will be made available on site. Emergency response plans will be developed and coordinated with the relevant national authorities;

• Waste management (see Chapter 18 Waste Management) includes recycling activities, for example vegetation removed from site will be used where possible for habitat improvement or composted;

• The lighting of fires will be strictly prohibited at all times during construction;

• Project workers will be forbidden from hunting or collecting wild plants and animals;

• The use of herbicides will be forbidden on-site;

• Any artificial lighting will be carefully located and directed to avoid light spill into adjacent areas;

• A detailed soil management strategy to ensure that topsoil from cultivated areas is not mixed with topsoil from non-cultivated areas. In addition, topsoil and subsoil will be stored separately. This is to retain integrity of seed banks and soil microbial composition;

• Measures to reduce the potential for soil run-off and scouring of bare soil following vegetation clearance; and

• Only the designated access roads shall be used to access the landfall section construction areas. Machinery shall not be allowed to move outside these access roads and construction areas. Traffic during the Operational Phase shall travel along designated routes, marked with clear and lasting markings.

The CMP will cross reference relevant measures contained within Appendix 11.3 Herpetile Mitigation Strategy that will require implementation throughout the construction period such as maintenance and protection of reptile exclusion fencing.

11.6.9.2 Designated Sites

The general mitigation measures (see Section 11.6.9.1) should be adhered to in order to avoid significant effects on designated sites (as described in Section 11.5.1.1).

11.6.9.3 Habitats and Flora

Habitats

The general mitigation measures shall be implemented to avoid significant effects on habitats during construction. This section on terrestrial habitats should be read in conjunction with Section 11.6.9.4 on fauna and Nikolski’s tortoise in particular.

Within areas of shishlyak, juniper woodland, mesophilic forest, and secondary steppe-fied meadow, habitats will, where possible, be reinstated to their pre-construction condition, with mitigation weighted in favour of ‘like for like or better’ habitat reinstatement. A habitat Reinstatement Plan will detail specifications for the restoration of different habitat types within the construction footprint. It will also include provisions for post-construction monitoring of
habitats, and will include adaptive mechanisms that allow modification of practices to ensure the objectives of the plan are met.

It will not be possible to allow deep-rooted trees and shrubs to establish over the Right of Way (RoW). The de-forested construction corridor will therefore be seeded with a native grass species, with the aim of creating a habitat similar to the existing steppefied meadows. It may be feasible to propagate and establish red-list species of plant within the area.

Consequently, it will not be possible to reinstate all shiblyak, juniper woodland, and mesophilic forest habitat subject to direct loss during construction. Table 11.35 below presents the areas of residual habitat loss (permanent loss) following implementation of the restoration and reinstatement mitigation measures presented above.

### Table 11.35 Areas of Residual Habitat Loss After Implementation of Mitigation

**Relevant IFC PS Requirements**

Paragraph 15 of IFC PS6 states that ‘In areas of natural habitat, mitigation measures will be designed to achieve no net loss of biodiversity where feasible’. It has been established that natural habitats within the Project Area include shiblyak and juniper woodland.

Paragraph 17 of IFC PS6 states that no project activities will be implemented in areas of critical habitat unless inter alia ‘The project does not lead to measurable adverse impacts on those biodiversity values for which the critical habitat was designated’. It has been established that, in terms of ecosystems within the Project Area, mesophilic forest is a threatened habitat type that confers critical habitat status under Criterion 4 (see Appendix 11.1). Based on the residual effect of habitat loss presented in Table 11.35 above, it is apparent that, despite the implementation of avoidance, minimisation, restoration, and reinstatement mitigation measures, the Project would not initially meet the requirements for no-net loss within the natural and critical habitats impacted. Additional mitigation is therefore proposed to comply with the requirements of IFC PS6.

$^8$ Temporary loss in this context refers to areas of habitat where it will be possible to reinstate habitat following completion of construction. It is recognised that it could take these habitats many years (more than 20 in the case of woodland) following reinstatement to reach their pre-construction condition.
Indeed, further to this under Paragraph 18 of PS6, a net gain in mesophilic forest is needed as the mitigation measures listed above are not expected to result in net gains. Options to mitigate residual loss of natural habitat and critical habitat will be explored and detailed in a BAP (which is specifically required by IFC PS6 Paragraph 18 when critical habitat is being considered).

**Freshwater Habitats**

Direct impacts to the Shingar River during construction will be avoided as the pipelines will be installed by micro-tunneling under the watercourse. It is also anticipated that significant impacts to the watercourse in the Graphova Gap will be avoided during construction by completing the works during the dry season. Despite this, unplanned incidents of pollution or an increase in silt or run-off within the river channels could potentially result in adverse impacts within the aquatic environment. Strict pollution control measures will therefore be employed at both locations; re-fueling operations shall be restricted to dedicated areas located at a distance greater than 50 m away from the watercourse. Spill kits, including floating booms will be available adjacent to the working area and all spills will be cleared up immediately. In addition to spill kits, silt trapping kits will be stored and available for use at the tributary location should rainfall occur during the construction period. Silt traps will be employed to ensure that the scheme does not result in an increase of greater than 20% above up-stream levels in suspended solids within the water column down-stream of the works area resulting in an adverse impact.

Further measures for the protection of watercourses are detailed in *Chapter 8 Terrestrial Soils, Groundwater and Surface Water*.

**Flora**

Where necessary, prior to the commencement of construction, RDB plant species within the construction area will be identified, and their location recorded using GPS. RDB species that have been recorded in the area include:

- Greek and stinking juniper;
- Pyramidal orchid;
- *Campanula komorovii*;
- *Salvia ringens*;
- *Linum hirsutum*; and
- Kavach peony.

In line with Russian statutory requirements, all protected plant species within the construction footprint will be moved to suitable alternative habitat outside the construction corridor and away from any potential effects. Translocation will be undertaken in accordance with measures to be contained within a detailed flora layout plan (to be produced). This document will be produced in association with local botanical experts.

Preservation of the seed bank through appropriate topsoil and subsoil storage during the Construction Phase will facilitate natural regeneration of the native species. Translocation of individuals back into the restored area will also be undertaken where appropriate, supplemented by propagation of seeds and cuttings.
Monitoring of the regeneration of these species will be included in the monitoring plan for the Project.

Rehabilitation of vegetation following completion of construction will be undertaken with due consideration to the existing natural vegetative assemblages in the wider local area. Native species of local provenance will be sourced as appropriate. The Habitat Reinstatement Plan will detail the appropriate restoration of the construction site.

### 11.6.9.4 Fauna

#### Invertebrates

The ESIA Report has identified potential negative effects of moderate significance on invertebrates resulting from the construction of the Project. Although it will be difficult to avoid impacts during construction, measures to reduce degradation to habitats adjacent to the construction sites will be employed to safeguard invertebrates supported within these areas (including Levantine skipper, which is a component of critical habitat). This will include:

- Restriction of the working corridor to limit the loss of invertebrate habitat; and
- Measures detailed within the CMP should be adhered to in order to avoid loss and/or degradation to invertebrate habitat adjacent to the construction corridor.

Furthermore, upon completion of the construction of the Project, continued implementation of the BAP to replace lost habitat and provide biodiversity enhancements to benefit invertebrates will be implemented. In particular, measures to address potential impacts to Levantine skipper will be incorporated to include a baseline survey to confirm presence or absence in the Study Area, provision of suitable habitats and a post-construction monitoring programme.

#### Nikolski’s Tortoise and All Other Amphibian and Reptile Species

This ESIA has identified the potential for the Project to result in negative impacts of high significance on Nikolski’s tortoise, and up to moderate significance on other species of herpetiles. Mitigation is therefore proposed to avoid impacts on these species. The mitigation measures described are incorporated into a detailed mitigation strategy (see Appendix 11.3) which provides a specification for mitigation measures to ensure that the Project does not result in a significant adverse impact on Nikolski’s tortoise, as well as on all other species of amphibians and reptiles. A summary of the mitigation strategy is given below:

*Construction Activity Prior to a Programme of Translocation Being Undertaken (the Varvarovka bypass road, only)*

- Should any construction activities to be undertaken during the herpetiles hibernation period dependent on annual climatic variation), such activities will be restricted to essential areas only;
- Prior to the commencement of construction of the temporary access roads, all areas of habitat which will be directly affected by construction will be fenced off using one way permanent reptile proof fencing; and
• All clearance activities within areas to be constructed during the hibernation period will be undertaken under a watching brief of the ECoW to maintain the strict observance to the working corridor.

Construction Activity after a Programme of Translocation Has Been Undertaken

• Prior to the commencement of construction, all areas of habitat which will be directly affected by construction and the habitat reinstatement areas will be fenced off using one way permanent reptile proof fencing;

• Pit-fall traps, artificial refuges and temporary internal fences will also be installed at this stage and all non-protected plant species, shrubs and trees will be removed by hand to a height of approximately 100 mm. All works will be completed under an ecological watching brief;

• On completion of the fencing works, a period of translocation will be completed in which the fenced area, traps and artificial refuges will be checked twice a day by ecologists and all reptiles and amphibians caught will be placed in areas of suitable alternative habitat outside the fenced areas. Any tortoises caught will be subject to full bio-metric measurement and all or a proportion of the population will be marked using a radio transmitter to assist with further population monitoring. The exact type of tag will be determined over the winter 2013/2014 to ensure the chosen technology will generate the most useful monitoring data as well as ensure that any system used will not have any adverse effect on the ecology or behaviour (including mating behavior) of the tortoise. All other animals caught during the translocation period will be recorded; and

• At the end of the movement, all internal fences, pit-fall traps and artificial refuges will be removed and the permanent fence maintained to ensure that no animals can enter the working area during the construction period. On completion of construction and all post-works and habitat reinstatement, all permanent fencing will be removed. Post-construction monitoring of the tortoise population will be undertaken as part of the ecological monitoring plan for the Project.

Under-road Tunnels

In order to mitigate against the impact of habitat severance and fragmentation, under-road tunnels will be constructed at appropriate locations along the alignment of both access roads to allow for the movement of tortoises and other herpetiles. The precise location and specification of these tunnels will be discussed and agreed with the Project’s contractors, but will conform to the following general principles:

• In accordance with good industry practice and published guidelines, the tunnels will be spaced at an appropriate distance and location (adjacent to suitable habitat along the Varvarovka bypass road) to ensure that there is a sufficient number and that they meet conservation objectives; and

• There will be fencing or barriers along the road to exclude tortoises from the working area.

No additional mitigation measures are expected, but would be subject to tunnel use which will be included as part of the tortoise monitoring programme.
Mitigation

The mitigation measures described above for Nikolski’s tortoise, a critically endangered species and component of critical habitat, are anticipated to substantially reduce the effect of the Project on this species. However, the long term effect remains uncertain. There is the potential for Project related mortality, disturbance (including to the breeding and hibernation cycle), long-term habitat loss (see impacts to shiblyak, juniper woodland, and mesophilic forest), and habitat severance, to affect the integrity of the local tortoise population (estimated to be in region of 2% – 5% of the population within the Abrau Peninsula). Furthermore, there is a risk that, if the integrity of the local tortoise population is affected, then this could also affect the regional (i.e. Abrau Peninsula) population.

Paragraph 17 of IFC PS6 requires a project to meet the following requirements before it can be implemented:

- ‘The project does not lead to measurable adverse impacts on those biodiversity values for which the critical habitat was designated’; and
- ‘The project does not lead to a net reduction\(^9\) in the global and/or national/regional population of any Critically Endangered or Endangered species over a reasonable period of time’.

Paragraph 18 of IFC PS6 goes on to state (in relation to critical habitat) that a project’s mitigation strategy must be designed to achieve net gains\(^10\) for the values which it has been designated (in this case, Nikolski’s tortoise).

Given the anticipated residual impacts, and high sensitivity of Nikolski’s tortoise, the Project would not be able to meet the requirement under paragraph 17 (i.e. the project will have an adverse impact which needs to be addressed), which would then lead to following paragraph 18 under which a net-gain would be required. A programme of biodiversity offsets may need to be proposed to ensure that the Project meets the requirements of paragraph 17 and paragraph 18 of IFC PS6 and would be determined through the BAP and after results of further studies as described below.

A population survey for Nikolski’s tortoise will therefore be undertaken in spring 2014. This survey will be a continuation of the study undertaken between October and November 2013 and will be undertaken in conjunction with local species specialists (this is likely to include Dr. Olga Leontyeva).

---

\(^9\) Net reduction defined as a singular or cumulative loss of individuals that impacts on the species’ ability to persist at the global and / or regional / national scales for many generations or over a long period of time. The scale (i.e. global and / or regional / national) of the potential net reduction is determined based on the species’ listing on either the (global) IUCN Red List and/or on regional/national lists. For species listed on both the (global) IUCN Red List and the national/regional lists, the net reduction will be based on the national/regional population.

\(^10\) Net gains are additional conservation outcomes that can be achieved for the biodiversity values for which the critical habitat was designated.
The requirement is provided below in two interlinked parts primarily to ensure ‘no net reduction’ and a monitoring research and conservation programme designed to ensure ‘net gain’. Based on the monitoring and knowledge requirements outlined above and in Appendix 11.3 Herpetile Mitigation Strategy, a potential strategy is outlined below:

- A BAP will be produced, with a significant component concerning the conservation of Nikolski’s tortoise. The BAP will be subject to periodic change based on monitoring and research results and the success of habitat management actions. The BAP will be independently peer reviewed;
- In order to demonstrate ‘net gain’ to the species, a monitoring programme of will be applied (i.e. have practical and research value). It is expected that the continuity in the management of this monitoring programme be maintained so that its data can be collated and applied to the activities described within the BAP;
- Research into the ecology and behaviour is crucial for any offset design and habitat management, especially in relation to hibernation, breeding, dispersal and mortality;
- Surveys of tortoise populations in adjacent habitats will be undertaken to gather further data on population density and define habitat suitability parameters;
- A robust, appropriately designed, and long-term biodiversity monitoring and evaluation programme will be integrated into the client’s environmental and social management plan. This will include key performance indicators on a higher level to ensure that the mitigation strategy and BAP is achieving its targets; and
- The longer-term monitoring and research programme should be designed in consultation with relevant international, national and local expertise, e.g. IUCN Species Survival Group, or an academic institute with relevant expertise.

**Birds**

This ESIA has identified potential negative impacts of low/moderate significance on breeding birds resulting from the construction of the Project. Mitigation is therefore proposed to minimize the magnitude of impact on breeding birds. The mitigation measures described will be incorporated into a detailed method statement for breeding birds prior to the commencement of construction, with advice from statutory nature conservation bodies as appropriate:

- Removal of nesting habitat will be undertaken prior to the breeding bird season (which is considered to be between March and September) to minimize the risk to breeding species. If this is not possible, a suitably experienced ecologist will check vegetation prior to removal for evidence of nests. If active nests of species of ecological importance are identified, an appropriate exclusion zone (approximately 5 to 10 m) will be established around the nest site until any young have fledged;
- Post-construction monitoring for the presence/absence of nesting birds within the working area should be undertaken as part of the ecological monitoring plan for the Project. These surveys would be robust enough to calculate population densities;
- Adherence to the CMP for Biodiversity and associated working method statements to avoid loss and degradation to habitats adjacent to the working corridor; and
• Development of a post-construction habitat management plan which will include timings for 
management operations along the Pipeline route (i.e. vegetation management will only be 
completed outside of the breeding bird season).

**Mammals**

**Bats**

The following measures are recommended to safeguard bats potentially roosting within the 
trees present within the mesophilic woodland:

• Construction-related lighting should be minimised as far as is possible and directed to avoid 
illumination of adjacent habitat;

• If the trees within the mesophilic forest are to be removed during the bat activity season 
(March – October), clearance works will be preceded by bat roost survey to determine bat 
presence / likely absence of roosting bats. If bats are found to be present, a soft felling 
process will be implemented where the trees are felled carefully under supervision of a 
suitably qualified ecologist. The section of tree containing the bat roost would be left in-situ 
over-night to enable bats to leave of their own accord; and

• A post construction plan will be implemented to replace lost habitat and provide biodiversity 
enhancements for bats.

11.6.10  **Residual Impacts: Construction and Pre-Commissioning**

11.6.10.1  **Designated Sites**

Assuming the general mitigation measures described above are implemented, the residual effect 
of the Project on designated sites will be *Not Significant*.

11.6.10.2  **Habitats and Flora**

**Habitats**

It is not possible to restore the lost habitat in its entirety post-construction given the 
requirement for the maintenance of a permanent de-forested way leave along the entire 
Pipeline route. However, where appropriate, the reinstatement of habitats and provision of 
compensatory planting is likely to reduce the magnitude of the impact on habitats from low to 
negligible in the medium to long term. Assuming these mitigation measures are successful, the 
residual effect of land take on habitats is assessed as being of no more than *Not Significant* 
significance due to a negligible impact on a receptor of up to moderate sensitivity.

**Flora**

Mitigation to implement targeted movement of red list plants will lower the magnitude of the 
impact to negligible. The sensitive storage of topsoil, subsoil and coastal sand to preserve the 
natural seed bank will also maximize opportunities for natural recolonization by notable flora. It 
is assessed that the residual impact on notable species is *Not Significant*. 
11.6.10.3 Fauna

Invertebrates

Mitigation measures aimed at reducing impacts on invertebrate habitat, as well as the proposed habitat reinstatement plan (aimed at benefiting invertebrates), are likely to reduce the impact of land take on invertebrates to negligible in the medium to long term. It is therefore considered that the residual effect of the Project on invertebrates will be Not Significant.

Herpetofauna

Mitigation measures will safeguard the tortoise during its active (non-hibernating) phase and reduce the impact magnitude of the Project activities on Nikolski’s tortoise (and other herpetiles) during this period from high to negligible.

Works undertaken during the hibernation period will potentially result in the mortality of a small number of tortoises and other herpetiles. In order to compensate for this loss and enhance the overall population in the long term, offsetting may be required. Assuming that monitoring demonstrates that mitigation measures undertaken are successful, it is assessed that the Project will result in a Not Significant residual impact on Nikolski’s tortoise and other herpetiles species in the long term.

Mammals

Bats

Mitigation measures will reduce the impact magnitude of the Project on roosting and foraging bats from low to negligible. It is therefore assessed that the Project will result in residual impacts on roosting bats of Not Significant.

All Other Mammals

Adherence to the general mitigation measures described above is likely to be sufficient to avoid significant effects on other mammals present within the Study Area. No additional mitigation for impacts on other mammals is considered necessary and the residual impact is assessed to be Not Significant.

Birds

Breeding Birds and Spring / Summer Migratory Birds

Habitat manipulation and sensitive timing of works to avoid breeding and migratory periods will reduce the impact magnitude of the Project on breeding birds from low to negligible. It is therefore anticipated that that the Project will result in residual effects on breeding birds of no more than Low.
Migratory and Over-wintering Birds

No mitigation for impacts on migratory and over-wintering birds is considered necessary and therefore the residual impact on these species is, as previously assessed, **Low**.

### 11.6.11 Assessment of Potential Impacts: Commissioning and Operational Phase

#### 11.6.11.1 Designated Site, Habitats and Flora

Operational impacts resulting from the Project are limited given that all of the significant impacts on habitats will have occurred at the Construction Phase. During the Commissioning and Operational Phase many of the mitigation measures for the impacts of construction (such as vegetation replanting) will occur. The overall impact of the Commissioning and Operational Phase will therefore be considerably lower than those during construction.

The overall impact on habitats during operation will be **Not Significant** due to the lack of any significant ground-works or other major works. The only activities that will be undertaken during this Project phase will be related to land remediation and maintenance of the RoW.

There is some potential for impacts on flora (including potentially red list species) as a result of maintenance to keep the RoW free of large trees and deep-rooted shrubs for the lifespan of the Project. However, considering that the worst case scenario of habitat and species loss for flora of conservation importance has been assessed for construction, the effect of operational activities is likely to be **Not Significant** (Table 11.36).

Complete.
11.6.11.2 Fauna

Invertebrates

During maintenance activities small scale works, machinery movements will occur. However, the location and scale of such disturbance will have no effect on invertebrates. The overall impact on invertebrates during operation will therefore be Not Significant.

Herpetiles

During maintenance activities small scale works and machinery movements will occur. There is potential for herpetiles, including Nikolski’s tortoise, to be present within habitats along the RoW during the Operational Phase. There is therefore some potential for killing and injury to these species during routine maintenance and inspection works. In the absence of mitigation, this could result in the death of individuals. This is assessed as a low magnitude impact on receptors of up to high sensitivity (Nikolski’s tortoise) resulting in an effect of Moderate significance.

Several species of herpetile will benefit from the creation of new open habitats (grassland) and habitat mosaics (interactions between open habitats and the woodland edges). For these species, replacement of woodland and forest with grassland at the Pipeline easement and its maintenance by removal of shrubs and trees is a creation of new suitable habitat and an ecological corridor for connection between patches of other open habitats.

Mammals

During maintenance activities small scale works, machinery movements and noise will occur. However, due to the localised nature and scale of activity the disturbance effects on mammals (including bats) are considered to be of a negligible magnitude, resulting in a Not Significant effect.

During operation, there will be some illumination during the hours of darkness. Lighting controls to minimize light spillage will be implemented. Any additional impacts of lighting are considered to be of negligible magnitude resulting in Not Significant effect.

Birds

There is some potential for breeding birds to be affected if vegetation clearance along the RoW is undertaken during the bird breeding season. Impacts would however be limited given that all of the significant impacts on species of conservation importance as a result of habitat loss will have occurred at the Construction Phase. The loss of this habitat and / or disturbance to these species would therefore be of no more than Low significance.

During operation, disturbance to birds will be limited due to the lack of any significant groundwork or other major construction works. There will be limited lighting at the landfall facilities which may disturb surrounding local habitat areas at night. Noise pollution will be limited to that generated by the presence of workers, vehicles and equipment during Pipeline inspection and RoW maintenance. Such impacts will be temporary and localised in nature.
The impacts will be limited to the Project footprint and are not predicted to result in disturbance to any additional areas. As a result, disturbance will occur in less than one percent of the available habitat within the local area and is considered to be of negligible magnitude. As a result, disturbance impacts during operation are considered to be **Not Significant**.

### 11.6.12 Mitigation and Monitoring: Commissioning and Operational Phase

#### 11.6.12.1 Designated Sites, Habitats and Flora

As no significant effects are anticipated at the Operational Phase, no mitigation or monitoring is recommended.

#### 11.6.12.2 Fauna

**Herpetiles**

Any Operation Phase vegetation management works (i.e. periodic cutting of vegetation along the Pipeline corridor) will be undertaken in the winter period only (between November and February) when the tortoises (and other amphibian / reptile species) are hibernating. Low-impact hand-held machinery will be used to complete this vegetation management. Vegetation will be cut to no lower than 100 mm and no ground should be broken during these works.

During the operation of the Pipeline, any maintenance / project vehicles will adhere to a strict on-site speed limit of 10 km/h and drivers must be mindful that tortoises could be present along any of the access tracks. For good practice, if an animal is observed and in immediate danger, it should be moved off the track. Any casualties observed will need to be recorded and reported to the project manager.

**Birds**

Vegetation clearance along the RoW should be undertaken outside of the breeding bird season (which is approximately between March and September) to avoid impacts on breeding birds.

**All Other Fauna**

As no significant effects are anticipated at the Operational Phase, no mitigation or monitoring is recommended.

### 11.6.13 Residual Impacts: Commissioning and Operational Phase

Assuming the mitigation measures described above for herpetiles and birds are implemented, residual impacts (Table 11.37) at the Commissioning and Operational Phase are expected to be **Not Significant**.

11.6.14 Assessments of Potential Impacts: Decommissioning

The South Stream transportation system is designed to operate for 50 years, although its life may be extended subject to close monitoring. The decommissioning program will be developed during the Operational Phase, and it is likely that the technological options and preferred methods for decommissioning of such transportation systems will be different in 50 years’ time.

Under the worst case scenario, whereby the Pipeline is removed from the ground (as opposed to being left in place), and activities associated with the Decommissioning Phase are likely to include the following:

- Construction of access roads / repair of existing facilities;
- Excavation works for the removal of pipes; and
- Dismantling and removal of the landfall facilities.

It is anticipated that the impacts associated with these activities; including habitat damage or degradation, killing, injury or disturbance to species, are unlikely to be of a magnitude greater than those reported for the Construction Phase (assessed and presented in Section 11.6.13 above). The significance of effects on ecological receptors is therefore not anticipated to be greater than those which have been reported for the Construction Phase.

11.6.15 Mitigation and Monitoring – Decommissioning Phase

As the impacts and effects are anticipated to be similar to those identified during the Construction Phase, the mitigation proposed for decommissioning will be the same as is proposed for the Construction Phase.

11.6.16 Residual Impacts: Decommissioning

Assuming the mitigation measures as are described in Section 11.6.3 are implemented appropriately no significant adverse effects are anticipated on terrestrial ecology receptors during construction. Impacts are therefore not anticipated to be of greater than Not Significant or Low adverse significance.

11.7 Demonstrating Compliance with IFC Performance Standard 6

The above sections have presented the baseline ecology present within the Landfall Project Area which has identified certain ecological receptors as contributing to the determination of critical habitat. These receptors are further discussed in Appendix 11.1. The assessment of residual impacts of construction, operation and decommissioning the Project on valued ecological receptors has taken in to consideration likely adverse impacts of the Project as well committed mitigation measures to avoid, reduce or mitigate for these impacts. The residual impact assessment has concluded that construction, operation and decommissioning of the Project will result in low / negligible adverse impacts on all ecological receptors, including those
which are components of critical habitats. Accordingly, it has been demonstrated that the Project will fulfil the requirement of Paragraph 17 of Performance Standard 6, which states the client will not implement any Project activities unless the following are demonstrated:

**Test 1 – no other viable alternatives within the region exist for development of the project on modified or natural habitats that are not critical**

Reasons for site selection and consideration of the alternative are presented and discussed in full in **Chapter 4 Analysis of Alternatives** of this document where it is clearly demonstrated that there are no viable alternative sites for this facility.

**Test 2 – the project does not lead to measurable impacts on those biodiversity values for which the critical habitat was designated, and on the ecological processes supporting those biodiversity values**

The residual impact assessment, which takes in to consideration all committed mitigation, has concluded that the Project will not result in any measureable impact on all identified and valued ecological receptors including those which are components of critical habitat. Mitigation including translocation of valued receptors, habitat reinstatement and development of areas of natural habitat as well as a long-term monitoring plan will ensure the Project will not result in impacts on valued receptors or ecological processes.

**Test 3 – the project does not lead to a net reduction in the global and / or national / regional population of any Critically Endangered or Endangered species over a reasonable period of time**

A robust monitoring plan will be developed by the client that will detail long-term monitoring ecological receptors, including those identified as components of critical habitat. The monitoring and management plan will also detail further measures to be completed if the monitoring demonstrates that targets set within this document are not being met (e.g. if the rate of establishment of planted trees is not met additional supplementary planting or additional aftercare will be completed to ensure robust reinstatement of habitats).

**Test 4 – a robust, appropriately designed, and long-term biodiversity monitoring and evaluation programme is integrated in to the client management programme**

As detailed in Test 3 this document will be developed and will detail long-term monitoring and management that will also include measurable targets against which to assess the mitigation and habitat reinstatement works. This plan will also include committed measures should the monitoring programme indicate that these targets are not being met.

### 11.8 Unplanned Events

The potential impacts associated with unplanned events are discussed in **Chapter 19 Unplanned Events**.

Unplanned events in the landfall section may occur during the Construction Phase from the use of construction plant, power generation equipment and from vehicular traffic in conjunction with equipment malfunction or human error. The resultant effects of these unplanned events will be limited to accidental pollution incidents involving fuel and oils, which could result in a significant
(major) adverse ecological impact especially if these pollutants enter watercourses. Fire is also a potential hazard and this could result in a significant (major) adverse impact on areas of terrestrial habitat outside the working area; especially in the forest areas. The design controls that will be in place to reduce the risk of occurrence of the above potential events, as well as the mitigation measures that will be enforced to minimise the consequences associated with the events, are discussed in **Chapter 19 Unplanned Events**.

During the Operations Phase, unplanned events are similar to those listed above for construction and would therefore be limited to isolated pollution risks associated with site inspection vehicles or maintenance tasks. Control measures for possible pollution incidents will be as detailed for construction. It is not anticipated that operational inspections, maintenance or habitat management will pose a significant fire risk.

### 11.9 Cumulative Impacts

The cumulative impacts associated with the Project relating to terrestrial ecology are assessed in **Chapter 20 Cumulative Impact Assessment**.

### 11.10 Conclusion

In the absence of impact avoidance and mitigation measures, the Project has the potential to affect a range of ecology receptors, including designated sites (Utrish SPNA, Kuban River Delta Ramsar, Delta of the Kuban River IBA, and Protective Forests), various natural habitats, and a number of red listed species (including the internationally Critically Endangered species, Nikolski’s tortoise). In the absence of mitigation, the effect on receptors has the potential to be of up to **High** significance.

The Construction and Pre-Commissioning Phase of the Project has the greatest potential to affect terrestrial ecology receptors. The key impacts relate to habitat loss and fragmentation, habitat degradation, direct mortality and injury to species, and severance. Impacts to habitats and species have been avoided through project design and, where appropriate, through a suite of mitigation measures which have reduced the magnitude of all impacts to low or negligible levels. The residual impacts on all species, regardless of their sensitivity, has therefore been assessed as being either **Not Significant** or of **Low** significance.

The chapter has also assessed the potential for the Project to have significant effects on terrestrial ecology receptors during the Commissioning and Operational Phase of the Project. Impacts at this phase are anticipated to be limited given that all of the significant impacts (such as habitat loss and fragmentation) on habitats and species will have occurred during the Construction and Pre-Commissioning Phase. In the absence of mitigation, there is the potential for the Project to have impacts of **Moderate** significance, largely due to the potential for routine maintenance activities to cause mortality or injure Nikolski’s tortoise and other herpetiles. Mitigation measures have been proposed which will reduce the magnitude of all impacts at the Operational Phase to negligible to low magnitudes. The residual effects on all receptors are therefore anticipated to be either **Not Significant** or of **Low** significance.
While it is not possible to fully assess decommissioning impacts at this stage, the ESIA has considered two scenarios: in situ abandonment and pipeline recovery. The ESIA has concluded that the former generates impacts broadly similar to those of the Pipeline’s Operational Phase, while the latter generates impacts broadly similar to the construction phase, and are thus amenable to similar mitigation strategies.

The assessment has been mindful of the requirements of IFC PS (6), particularly in relation to the identification and consideration of critical habitat. A critical habitat assessment has been undertaken which has identified a number of ecological receptors which qualify as components of critical habitat. In accordance with IFC PS (6), mitigation measures (including provision of a BAP) have been designed and will be implemented to achieve a net biodiversity gain for these receptors.

The chapter has also assessed the potential for the Project to have cumulative impacts with other schemes within the vicinity of the landfall section. The cumulative impact assessment has identified a number of areas where adverse cumulative effects could occur due to the construction of the Project and the Russkaya CS development. Although the Project is not anticipated to make a significant contribution to cumulative effects, the importance of South Stream Transport engaging with Gazprom Invest to align Gazprom Invest’s mitigation measures with those of the Project has been highlighted. This communication and alignment is considered to be important to avoid adverse cumulative effects on terrestrial ecology receptors within the wider environment.

12 Marine Ecology

12.1 Introduction

This chapter presents an assessment of the Project’s impacts on marine flora and fauna within Russian Federation waters encompassing Russian territorial waters out to 12 nautical miles (NM) and the Russian Exclusive Economic Zone (EEZ) of the Black Sea. The assessment considers impacts arising during the Construction and Pre-Commissioning, Operational and Decommissioning Phases. The most important impacts are predicted to arise during the Construction and Pre-Commissioning Phase. Construction activities, including dredging, seabed intervention and physical placement of the Pipeline on the seabed, have the potential to result in the loss of habitats and directly or indirectly affect associated plant and animal species.

Along the eastern Black Sea coast, faunal groups of particular interest, either due to their value or vulnerability, include a variety of commercial fish species (e.g. anchovy, turbot, sprat etc.), endangered species (e.g. sturgeon), marine mammals and seabirds. Marine flora is also important, particularly red and brown macroalgae. These are discussed further in Section 12.4.

The assessment has identified sensitive ecological receptors (including protected and/or notable habitats and species) within the Project’s Area of Influence (as described in Section 12.3.2).

This chapter provides a description of the baseline conditions, assessment methodology, regulatory framework, the measures required to mitigate any significant adverse effects of the Project’s Activities and the likely residual impacts assessed after these measures have been employed. The potential for cumulative impacts with other projects in the surrounding area is also considered.

12.2 Scoping

The scope of the marine ecology impact assessment for the Project was defined through a process that identified ecological receptors and potentially significant impacts related to the Project. Baseline information which informed the scoping process largely drew on information gathered from studies undertaken for the South Stream Offshore Pipeline, including feasibility, engineering and environmental surveys carried out in 2009 to 2013 (Section 12.3.3). Key steps in the scoping process for marine ecology comprised the following:

- The Project’s Front End Engineering and Design (FEED) was reviewed to identify activities with the potential to significantly affect ecological receptors;
- Ecological receptors within the Project Area of Influence were identified through a review of secondary data, surveys undertaken for the Project (as described in Section 12.3.3), and professional expertise;
- A review of relevant national and international legislative requirements and lender requirements for compliance; and
- An Environmental Issues Identification (ENVIID) was undertaken to assist in the identification of impacts and receptors. During the ENVIID process, each activity was
examined to understand how activities were expected to interact with ecological receptors, which receptors would be impacted and the nature (positive or negative) of the likely impact. The outcome of the ENVIID was an ENVIID register which identified the various elements of the Project and their interaction or potential impact on sensitive ecological receptors.

The marine environment contains many potential receptors and is, therefore, an important consideration in the ESIA process. Marine ecological receptors are diverse and include a wide variety of organisms and habitats. For the purpose of this assessment, marine biota is broadly grouped into the following topics: plankton, benthic communities, fish, seabirds and marine mammals. In addition, the habitats that these organisms inhabit and the ecological processes of these habitats are considered as receptors. Species of conservation value, critical habitats and protected areas are discussed in terms of their importance and in terms of the potential impact that the Project may have on them.

The potential occurrence of species of conservation value was identified using the following sources:

- International United Conservation Network (IUCN) Red Data List (RDL);
- Red Data Book of the Russian Federation (RDBRF); and
- Red Data Book of the Krasnodar Krai region (RDBKK).

### 12.3 Spatial and Temporal Boundaries

#### 12.3.1 Project Phases

This chapter has appraised the potential for the Construction and Pre-Commissioning, Operational and Decommissioning Phase activities of the Project, to have impacts on receptors. Decommissioning is considered in less detail, see Section 12.5.4.

#### 12.3.2 Project Boundaries

##### 12.3.2.1 Project Area

As described in Chapter 5 Project Description, the Project Area is divided into landfall, nearshore and offshore sections. This division is based on technical consideration of different construction activities to be employed in each section, and therefore the terms ‘nearshore section’ and ‘offshore section’ have no ecological meaning in this sense.

The landfall section includes four microtunnels that extend from onshore entry shafts, seaward, under the shoreline and under the seabed, to emerge from the seabed at a water depth of about 23 m, approximately 400 m from the shoreline. The nearshore section then extends from the exit point of the microtunnels for approximately 425 m to the pipeline tie-in with the offshore section at a water depth of about 30 m. The offshore section then extends from this point for approximately 225 km to the boundary between the Russian and Turkish EEZs.
For the purpose of this chapter on marine ecology, the nearshore is considered to also include the area from the shore to 23 m water depth, a distance of approximately 400 m which forms part of the “landfall section” as described for engineering reasons. Because these two sections of the Project Area are ecologically contiguous, they are considered as one in this chapter. From the microtunnel exit point the pipelines will be buried in trenches to a depth of approximately 2.5 to 3 m for a distance of approximately 170 m. From here, out to the edge of the nearshore section (30 m water depth), the pipelines will be coated in concrete and laid directly on the seabed.

During the Construction and Pre-Commissioning Phase of the Project the nearshore section of the Project Area is defined by the maritime safety exclusion zones around the construction vessels, extending out 3 km either side of the outermost pipeline, encompassing:

- The area impacted by sediment dispersion, based on sediment models;
- The route of the four individual pipelines;
- The likely anchor spread and movement locations of vessels directly associated with the pipeline installation and maintenance; and
- The proposed microtunnel exit pits.

The nearshore section Project Area (see Chapter 5 Project Description for further details) is approximately 5.2 km².

The offshore section is approximately 225 km in length and pipelines will be laid directly on the seabed from the maximum water depth where dredging works will take place (30 m water depth), to the boundary between the Russian and Turkish EEZs. The offshore section of the Project Area is primarily defined by the maritime safety exclusion zones around the construction vessels either side of the outermost pipeline. The Project Area of the offshore section consists of a corridor of 3 km from the boundary of the nearshore section to the 600 m water depth contour, after which the corridor decreases to 2 km width either side of the outermost pipeline from the 600 m water depth contour to the EEZ boundary. The change in corridor width is based on the type of pipe-lay vessel used (Chapter 5 Project Description). The offshore section of the Project Area encompasses:

- The route of the four individual pipelines; and
- The likely anchor spread and movement locations of vessels directly associated with the Pipeline installation and maintenance.

The offshore section is approximately 1,080 km² which is 206 km² from the nearshore boundary to the 600 m water depth contour and 874 km² from this to the EEZ boundary.

During the Operational Phase the Project Area will be smaller, defined by the operational exclusion zone of 0.5 km either side of the outside pipelines from the microtunnel exit point to the Russian / Turkish EEZ boundary (end of offshore section).

### 12.3.2.2 Study Area

The Study Area, or Zone of Influence, for the marine environment has been defined as the area that will encompass the largest extent of predicted potential impacts. In order to capture all
impacts, including long range acoustic disturbance, this has been set at a nominal 100 km distance from the Project Area. The baseline study (both secondary and primary data) covers this Study Area. Relevant areas to survey within the Study Area have been determined based on the nature of individual receptors as described below.

12.3.2.3 Survey Areas

Surveys undertaken in 2013 (Section 12.3.3.3) were within the boundaries of the Study Area. The locations of and information related to these surveys are displayed in Table 12.1 and Figure 12.1. Survey Areas refer to the locations in which surveys were conducted for the Project during the feasibility and design stages from 2009 to 2013. The locations of and information related to these surveys (Ref. 12.1; Ref. 12.2) are displayed in Table 12.1 and Figure 12.1. The Survey Areas are separated for each topic (i.e. plankton, seabirds, etc.) and are defined under the topic headings in Section 12.4. Figures within each topic heading show the extent of the Survey Areas for each topic. These figures are:

- Plankton: Figure 12.2;
- Benthic: Figure 12.4;
- Fish: Figure 12.10;
- Seabirds: Figure 12.11 and Figure 12.12; and
- Marine mammals: Figure 12.17.

12.3.3 Baseline Data

Secondary data (i.e. data from third parties not specifically acquired for the Project, including literature reviews, etc.) and existing primary data (i.e. data acquired specifically for the Project through dedicated surveys) were reviewed prior to scoping. Following this, a data gap analysis was conducted and surveys to collect additional primary data were specified. The majority of the baseline information used to support this chapter comes from the results of marine surveys specifically conducted for the Project from 2009 to 2011 (Ref. 12.1), and in 2013 (Ref. 12.2). Details of the survey scopes are given in Section 12.3.3.3.

12.3.3.1 Secondary Data

Where possible, this assessment is based on primary data. Secondary Data were also consulted to inform the baseline of this chapter, as described below:

- The 2009 to 2011 survey reports (Ref. 12.1) included a thorough review of Russian published scientific literature that has been incorporated into this baseline as appropriate;
- Other recent published scientific literature was identified through a British Library data search;
- International, Federal and Regional Red Data Books were consulted in order to identify the potential presence of notable plant and animal species within the Survey Area (Ref. 12.3);
- Designation information for Utrish Specially Protected Natural Area (SPNA) was obtained from a 2009 World Wildlife Fund (WWF) report (Ref. 12.4);
• Information on fish, benthic communities, macroalgae and historic changes in the Black Sea flora and fauna are found in the Black Sea Commission “State of the Environment” reports (Refs. 12.5 to 12.11); and

• Other accounts of Black Sea ecology have been produced by regional NGOs and multilateral organisations e.g. the Agreement on the Conservation of Cetaceans in the Black Sea, Mediterranean Sea and contiguous Atlantic area (ACCOBAMS) (Ref. 12.12).

12.3.3.2 Data Gaps

As part of the data collection exercise, a gap analysis was conducted to identify areas where existing baseline data were insufficiently detailed to allow for a robust assessment. Furthermore, as the project design has evolved, the potential footprint of the activities has changed. Where secondary data were insufficient to meet these requirements, additional surveys were performed to:

• Increase the data coverage of some surveyed areas, by a combination of denser sampling and the use of underwater video and still photography; and

• Collect data along the modified pipeline alignment, in temporary spoil storage areas and in the proposed spoil dumping ground as well as in areas where the pipeline route changed from the route originally surveyed in the 2009 to 2011 surveys (Ref. 12.1).

The additional surveys undertaken to address the identified data gaps included:

• Benthic ecology surveys;
• Sediment sampling; and
• Visual seabird and marine mammal surveys.

12.3.3.3 Primary Data / Baseline Surveys

A series of marine surveys was conducted between 2009 and 2011 to collect data on marine ecological receptors that might be impacted by the project. These surveys collected ecological and physico-chemical data over a wide area and during several seasons. These surveys served to establish the broad environmental parameters of the Study Area, albeit at relatively low resolution.

Following the gap analysis described above, additional surveys were undertaken in 2013 to:

• Verify and supplement the findings of the previous benthic surveys (Ref. 12.1) in order to obtain a robust benthic habitats map for the assessment of impacts and to act as a baseline for future monitoring; and

• Expand the survey data set to capture areas which have the potential to be affected by the Project that were not previously surveyed, following finalisation of the pipeline alignment.

Table 12.1 and Table 12.2 list the marine ecology surveys undertaken. The survey sampling stations are shown in (Figure 12.1). Survey methodologies are summarised in Table 12.3.

* A Niskin Bottle can be opened at both ends and the open bottle is lowered into the ocean on a wire from a Research Vessel until it reaches a certain depth and then the bottle is closed.

** A method used to determine the extent of Photosynthesis in an aquatic Ecosystem. Duplicate portions of a water sample are collected. One portion is incubated in a clear bottle, and the other is incubated in a dark, light-impermeable bottle. Following incubation for a prescribed time period, the net uptake of carbon dioxide in each is measured and compared.

† The Secchi disc is mounted on a pole or line, and lowered slowly down in the water. The depth at which the pattern on the disk is no longer visible is taken as a measure of the transparency of the water.

12.3.4 Data Assumptions and Limitations

In order to carry out this assessment, certain assumptions have been made regarding the input data, and it is acknowledged that some of the data used in the ESIA Report have attendant limitations:

- The assessment is based on a Project description that may be refined during detailed design. Nonetheless, the key design parameters are understood and the ESIA Report is based on these, with additional mitigations specified as appropriate. Design changes which may impact the results of this ESIA Report are captured in the management of change process discussed in Chapter 5 Project Description;

- Environmental standards may evolve during the lifetime of the Project. It is not possible to predict such changes but reference to Good International Industry Practice (GIIP) minimises the effect of this uncertainty;

- It has not been possible to provide definitive temporal trends in the baseline due to the differences in season of the various surveys undertaken. The two surveys that coincide (summer 2009 and summer 2013) are far enough apart that comparisons can only be tentative;

- Description of the deep sea environment is based on acoustic data interpretation as well as, some limited visual material and this makes it subjective to a degree. However, given the absence of potentially biogenic deep sea features in the Russian sector, this is not considered a risk to the assessment;

- There are no spatially continuous habitat data, thus mapping is the result of interpolating spot samples. Given the number of samples collected in the 2013 survey, this is considered adequate for the purposes of the assessment, but some uncertainty remains; and

- The ecology of seabirds and marine mammals in the Russian sector is not well understood (in terms of accurate details on migration, breeding etc.). Surveys undertaken for this Project give data on distribution but cannot provide this level of detail.

12.4 Baseline Characteristics

12.4.1 Black Sea Overview

The Black Sea is a semi-enclosed basin and is one of the most isolated from the major world oceans. It has connections to the Mediterranean Sea through the Bosphorus Strait and the Dardanelles Strait in the south-west, and with the Sea of Azov in the north-east through the Kerch Strait. It is a largely brackish water body, with a salinity of 17 to 18‰ on average, due to the massive freshwater influx from rivers including the Danube, Dnieper and Don via the Sea of Azov.

There are two layers of water with different salinity in the Black Sea. An upper brackish layer, with an average salinity of 17‰, results from the massive freshwater influx from rivers including the Danube, Dnieper and Don via the Sea of Azov. Below this is a layer of higher salinity seawater (20 to 30‰), originating from the Mediterranean. This stratification, which
creates a distinct and permanent pycnocline¹ around 150 to 200 m, limits the vertical exchange of water between the surface and deeper waters creating a unique chemical and biological environment. Further details of environmental quality, hydrodynamics and seabed dynamics are set out in Chapter 7 Physical and Geophysical Environment.

These chemical and biological characteristics have resulted in the following broad marine habitat types in the Black Sea:

- **Surface waters (typically 0 to 50 m water depth)** are well oxygenated and have a fairly low salinity (typically 18-22‰). Because this zone is photic, it is biologically productive and has historically supported large populations of pelagic fish. There are a number of different benthic habitat types within these shallow waters:
  - Rocky substrates are present throughout the shallow area, including the supralittoral sea cliffs. Hard substrata are important as they allow the development of macroalgal beds that in turn support a highly diverse array of fauna;
  - Sandy sediments are also present in shallow areas where material has been deposited and wave energy has winnowed out fine material. These zones support a range of infaunal communities, typically bivalve dominated; and
  - Mud sediments are present in some low energy areas between 10 to 20 m water depth supporting infaunal communities.

- **Mid-depth waters (approximately 50 to 100 m water depth)** show decreasing oxygen concentrations and increasing salinity due to the influence of the bottom layer. This is typically referred to as the suboxic zone where the concentrations of both oxygen (O₂) and hydrogen sulphide (H₂S) are extremely low and do not exhibit any perceptible vertical or horizontal gradients (Ref. 12.13). Benthic habitats at these depths, where wave energy at the seabed is largely absent, are often muddy sediments; and

- **In deep waters (below about 150 to 200 m)** conditions are anoxic, and together with increased H₂S concentrations, restrict the vertical distribution of pelagic and bottom-dwelling metazoan organisms. This lower water layer accounts for as much as 87% of the Black Sea. Muddy sediments predominate in deeper waters, and while little is known about the benthos of the deep Black Sea, chemosynthetic bacteria can occur here. For example, in the anoxic shelf of the north-western Black Sea numerous gas seeps are populated by methanotrophic microbial mats that can form tall reef-like structures, though such have not been detected along the Pipeline route in the Russian sector (Ref. 12.5 and Ref. 12.14).

The Black Sea has a very large catchment area to sea surface area ratio and a densely populated coastal zone, making it highly vulnerable to pressure from land-based human activity. Rapid economic development and a lack of adequate management of marine resources in the later decades of the 20th century resulted in major environmental and ecological changes in the Black Sea. In particular, eutrophication from land-based sources resulted in changes to the diversity and distribution of flora and fauna throughout the Black Sea ecosystem.

---

¹ A pycnocline is the cline or layer where the density gradient is greatest within a body of water. Formation of pycnocline may result from changes in salinity or temperature.
Eutrophication gave rise to massive increases in primary production and a shift in the abundance and composition of phytoplankton species in the Black Sea. Larger and more frequent algal blooms increased the flux of organic matter to the seabed inducing a sharp decline of dissolved oxygen and a silting of benthic communities in many areas. Increased incidence of harmful algal blooms (red tides) caused fish kills and the increased turbidity of the water column reduced light availability to benthic macrophytes and seaweeds in deeper waters. The distribution and extent of many algal species, including the red alga Phyllophora and the brown Cystoseira barbata, that inhabits rocky coasts, have reduced considerably in many areas of the Black Sea including the Russian coast.

There have been corresponding changes in zooplankton, with the loss of some species and a shift from larger to smaller species of crustacean. There has also been a sharp increase in the number of gelatinous species such as jellyfish, although the most drastic change in the zooplankton communities resulted from the invasion of the ctenophore, Mnemiopsis leidyi. This species is a voracious predator of copepods, which are important prey items for larval and juvenile fish (Ref. 12.15), and is a direct predator of fish eggs and larvae. The negative effects of this invasion are only recently showing signs of reversal.

Other human activities, in particular uncontrolled fisheries have added to the change in the structure and dynamics of the biology of the Black Sea.

Since the early 2000s, the governments of the Black Sea coastal states have adopted a basin wide approach to pollution prevention, with a strategic goal of restoring the ecological status of the Black Sea to a condition similar to that of the 1960s. Pollution pressure from land based sources although still intense shows a decreasing trend and some improvements in ecological status have been observed. For example, some species that disappeared appear to be recovering and the number and intensity of algal blooms is reported to be lower for all areas (Ref. 12.10).

Information presented in this report on benthic communities focuses on shallower waters of less than approximately 200 m because the diversity and abundance of benthic fauna and flora decreases rapidly with increasing depth due to decreasing light, increasing anoxia and high concentrations of H₂S. Beyond 200 m conditions are completely anoxic. The seabed of the deeper parts of the Black Sea is therefore unlikely to support significant macro- or meiofaunal communities (Ref. 12.9). Microbial reefs associated with mud volcanoes or “gas seeps” are known to occur in waters deeper than 200 m in some western areas of the Black Sea (Ref. 12.16); however, none have been recorded in the Study Area.

This section on baseline characteristics describes the marine habitats, flora and fauna of the Study Area and has been separated into the following sub-sections:

- Plankton;
- Benthic communities;
- Fish;
- Seabirds;
- Marine mammals; and
12.4.2 Plankton

12.4.2.1 Background

Plankton forms the basis of marine food webs and is therefore essential to the structure and functioning of marine ecosystems. As phytoplankton are photosynthetic, they are generally confined to the euphotic zone – the depth of water exposed to sufficient sunlight for photosynthesis to occur; in the open ocean this is typically around 200 m, although in the Black Sea it is in the order of 50 m. Vertical distribution of plankton in the Black Sea is also influenced by the decrease in oxygen from 50 to 100 m water depth (Ref. 12.9).

Significant changes in the phytoplankton community were observed within the Black Sea between 1985 and 1994. The existing seasonal succession pattern of a spring diatom bloom followed by blooms of dinoflagellates and then phytoflagellates was disrupted, with a reduction in the diatom component of the spring bloom. This fundamental shift still persists. The reasons for this are not clearly understood, but a variety of natural and anthropogenic causes have been postulated, including a cold period from 1985 to 1994 (Ref. 12.10), hot summers and early warming of the surface layer (Ref. 12.1), damming of the Danube River and a reduction in silicate inputs (Ref. 12.17), and a reduction in inorganic nutrients allowing coccolithophorids to more successfully compete with diatoms (Ref. 12.1).

Historical changes have also occurred in the zooplankton of the north-eastern shelf of the Black Sea, particularly through the accidental introduction of the predatory ctenophore (comb jelly), *Mnemiopsis leidyi*. This introduced species preyed on the indigenous plankton of the Black Sea which led to a major decline in copepod (a type of planktonic crustacean) populations (Ref. 12.7). This situation persisted until 1997 to 1998, with another accidental introduction, possibly from ship ballast water, of the ctenophore *Beroe ovata* (Ref. 12.6). This species is the main predator of *M. leidyi* and subsequently the zooplankton community began to recover both in species composition and abundance (Ref. 12.18).

12.4.2.2 Plankton Survey

Survey Area

Plankton samples were collected at the locations shown in Figure 12.2. Bacterioplankton, phytoplankton, zooplankton and ichthyoplankton were analysed. Summary information on the water depth, distance from shore, as well as survey methodologies is provided in Table 12.1 and Table 12.3.

Survey Results

Phytoplankton and Primary Production

In autumn (November) 2010, 75 species of phytoplankton were recorded from a total of eight sampling stations. Dinoflagellates represented 52% of the total number of species and were more abundant in the northern samples of the Survey Area (Stations 1 to 3 in water depths of 32 m and 87 m respectively). Diatoms comprised 29% of the total number of species and were more abundant in the south of the Survey Area, around Gelendzhik (Stations 18 and 19 in water depths of 95 m and 25 m respectively) (Ref. 12.1, Table 12.4).

Note: L-B = littoral-benthic species,* - alveolates are protists and include protozoa, ciliates and dinoflagellates

Phytoplankton of the Survey Area were typically marine, with some species associated with lower salinity observed in the surface layer at Stations 1, 18 and 19 (in water depths of 32 m, 95 m and 25 m respectively). However, the contribution of these low salinity species to the community abundance was not substantial; accounting for 8% of the total number of phytoplankton species. In the autumn of 2010, the coccolithophorid *Emiliania huxleyi* was the dominant species in terms of abundance at all stations (Table 12.5).

</tbody>
</table>

For all stations and depths sampled in autumn 2010, the greatest contribution to phytoplankton biomass was made by dinoflagellates (up to 90%, Station 19, depth of 0 m), small flagellates (up to 84%, Station 18, the near-bottom layer) and coccolithophorids (up to 50%, Station 1, depth of 30 m). Maximum phytoplankton biomass was, unsurprisingly, recorded in the well-lit surface layer (Ref. 12.1) and generally, the biomass of near bottom samples at all stations was half that of the surface layer most likely because of lower light levels. However, high variability in phytoplankton biomass was observed, a feature typical of phytoplankton populations.

In spring (April) 2011, 75 species of phytoplankton algae were recorded from 14 stations in the Survey Area. Dinoflagellates (52% of the total number of species) dominated in terms of number of species. Diatoms (37.4% of the total number of species) ranked second by abundance after coccolithophorids. There was a high percentage of littoral-benthic forms (up to 64% of the number of diatoms) in the water column as a result of intensive mixing at the shallow-water stations (Stations 1, 2 and 19; less than 30 m water depth). In coastal shallow
waters, up to 30 m water depth, a fairly uniform vertical distribution of algae was observed (Ref. 12.1). The highest abundance of phytoplankton was observed at Stations 2 and 19 in 17 m and 25 m water depth respectively.

In spring 2011, when the contribution of picoplankton is discounted, coccolithophorids dominated the total biomass. This is comparable to 2002-2009 data collected from the north-eastern shelf of the Black Sea although a lack of information regarding survey methodology creates a level of uncertainty with this comparison (Ref. 12.1).

A comparison of the dominant species in terms of number between autumn 2010 and spring 2011 surveys is shown in Table 12.5. The data show that phytoplankton are more abundant around the time of the seasonal spring bloom (March to May) as would be expected (Table 12.5).

In summer 2011, 13 species of phytoplankton were recorded at Station 4c. The main contribution to the biomass was from the diatom Pseudosolenia calcar-avis (approximately 56% of the total biomass).

Data on primary production and photosynthetic pigment concentration in the Survey Area in spring 2011 are consistent with published data for the spring period of other years (Demidov, 2008 in Ref. 12.1). Two coastal stations (Stations 18 and 19 near Gelendzhik, at water depths of 95 and 25 m respectively) had higher concentrations of chlorophyll and other pigments, possibly due to anthropogenic eutrophication (Ref. 12.1). The biomass of phytoplankton and annual primary production in the Survey Area suggests a mesotrophic nutrient status in the Survey Area (i.e. water containing moderate levels of inorganic nutrients) (Ref. 12.1). Low values for primary production were recorded in Spring 2011 at stations 18 and 19 (in water depths of 95 m and 25 m, respectively) which was attributed to an increase in suspended sediments and corresponding turbidity of the water column and a result of a storm event (Ref. 12.1.).

**Zooplankton**

Zooplankton samples were collected in autumn 2010 and spring 2011 (Figure 12.2) at the following locations:

- Stations 1 to 4, 6, 8, 17, 18, 19 in November 2010;
- Stations 1-3, 6, 8, 9, 10, and 13 to 19 in April 2011; and
- Station 4c in August 2011.

Surveys conducted in autumn 2010 (Ref. 12.1) identified 24 species of zooplankton (Figure 12.6), including meroplankton². Copepods were the most diverse component of the community and dominated zooplankton abundance at most stations. Across all samples, copepods accounted for an average of 86% of total biomass. Other permanent members of the zooplankton were chaetognaths (arrow worms), ctenophores (comb jellies) and larvaceans (pelagic tunicates) and the meroplankton was composed of the larvae of benthic groups such as bivalves, gastropods, ascidians and barnacles. Arrow worms accounted for an average of 12%²

---

² Species which are only planktonic for some stages of their life cycle
of total biomass. The greatest abundance of zooplankton was at Stations 2 and 18 (in water depths of 17 m and 95 m, respectively).

In April, 2011, 14 species of zooplankton were recorded from 14 samples in the Survey Area (Table 12.6) and the dominant taxa were the copepod crustaceans which accounted for between 68 and 96% of total abundance. Large heterotrophic dinoflagellates and the larvae of molluscs were the next most abundant groups. Highest abundance values were observed at Stations 6 and 8 which are located around 1,500 m water depth near the continental slope edge (Ref. 12.1). The number of species of the meroplankton, primarily the larvae of benthic species, was much lower in spring 2011 compared to autumn 2010.

*Note:* H = Holoplankton (permanent plankton) M = Meroplankton (temporary plankton e.g. larvae etc.)

The abundance and biomass of zooplankton was spatially highly variable. This difference between stations is typical of the highly patchy nature of zooplankton. Abundance varied between 78 and 3990 individuals/m³ and biomass from 2 to 1001 mg/m³ per station. Stations located in depths less than 150 m (Stations 1 to 3, 18 and 19) were characterised by large biomass, but lower abundance of zooplankton due to the presence of larger animals such as arrow worms. Station 6 and 8 (water depth of around 1,500 m) had the greatest zooplankton biomass (Figure 12.3).
The biomass of zooplankton was lowest in Stations 1, 2, 3 and 19 (water depths of less than 100 m). In terms of numbers, the community was dominated by arrow worms such as *Sagitta* sp. and mature stages of copepods. Predatory species such as *Sagitta setosa* and the ctenophore *Pleurobrachia rhodopis* dominated the biomass in the majority of deep water stations (i.e. stations in water depths of > 1,500 m) (Ref. 12.1).

Only 11 species of zooplankton were recorded in summer 2011 as only one location was surveyed; Station 4c at less than 20 m water depth (Figure 12.2). Cladocerans dominated the zooplankton community, comprising almost half the abundance and 45% of the biomass. The thermophilic cladoceran *Penilia avirostris* was the most common species (Ref. 12.1).

**Figure 12.3 Zooplankton Biomass (g/m³), Spring 2011**

Ichthyoplankton

Ichthyoplankton samples were collected in 2010 and 2011 (see Figure 12.2) at the following locations:

- Stations 1 to 3, 6, 8 and 17 to 19 in November, 2010; and
- Stations 1 to 3, 6, 8, 9, 10 and 13 to 19 in April, 2011.

During the November 2010 survey, the only ichthyoplankton recorded were eggs and larvae of sprat (*Sprattus sprattus*) and whiting (*Merlangius merlangus*). This could be due to the survey period not coinciding with the reproduction period of most fish inhabiting this area of the Black Sea (Ref. 12.1). The maximum abundance in 2010 was observed in coastal areas with the maximum abundance of eggs recorded at Station 1 and larvae at Station 19 in 32 and 25 m water depth respectively (Table 12.1).
Eggs and larvae of fish were determined at almost all stations of the survey. In April 2011, eggs and larvae of sprat were determined at only three of the stations (Station 3, 8 and 17). However, in almost every sample there were young fish of launce (*Gymnomodytes cicerelus*), blennies (*Blennius sp.*) and stickleback (*Pungitius sp.*). During the April 2011 survey, larvae of sprat and prickly pipefish (*Syngnathus phlegon schmidtii*) were most numerous (Ref. 12.1).

There were no larvae of any fish species of conservation concern (IUCN Red List or national / regional Red Data Books) collected from either survey.

### 12.4.2.3 Summary

The phytoplankton community observed in Russian waters was composed of typical marine species, some of which are found in lower salinities. The number of species observed was different between surveys with 75 species recorded from eight stations in spring 2010 and 75 species recorded from 14 stations in autumn 2011. In both surveys, species composition was dominated by dinoflagellates (just over half of all species) and diatoms (around 30%). In terms of abundance small flagellates (a group which can contain some dinoflagellates) dominated the phytoplankton in both surveys. In both 2010 and 2011, phytoplankton species were more abundant at stations in less than 100 m water depth and the highest abundances were generally recorded at the surface. This is to be expected as phytoplankton are photosynthetic species and are usually observed in highest numbers in this euphotic zone which, extends to a depth of 50 m in the Black Sea.

The biomass and production of phytoplankton in the Survey Area suggests a mesotrophic nutrient status which means that the waters are moderately productive with moderate nutrient levels.

Copepods were the most diverse component of the zooplankton community and were dominant in abundance at most stations in 2010 and 2011. In both years, the main contribution to the total biomass comprised four groups; copepods, ctenophores, arrow worms and flagellates. In April 2011, highest abundance values were observed at Stations 6 and 8 which are located around 1,500 m water depth near the continental slope edge whereas in November 2010, the greatest abundance of zooplankton was at Stations 2 and 18 (in water depths of 17 m and 95 m, respectively).

For ichthyoplankton, the difference in the composition during the autumn (2010) and spring (2011) periods corresponded to the reproductive periods of fish. The results of spring investigations in 2011 are comparable with stock data of AzNIIRKh (Azov Research Institute of Fish Industry) for different sectors of the Russian Sector of the Black Sea (Ref. 12.1).

In general, plankton species abundance and biomass was variable and greatest in the spring surveys which correspond with the seasonal bloom in phytoplankton and in turn zooplankton species.
12.4.3  Benthic communities

12.4.3.1  Background and Literature Review

Overview

The northeast region of the Black Sea has historically been considered to comprise two distinct regions: from the Kerch Strait to around Anapa and Gelendzhik in the north, and from Anapa and Gelendzhik to Adler in the south (Ref. 12.6). The oceanography and ecology of these two areas is understood to be distinct, and they have been variously affected by the changes that have affected the entire basin over the last few decades.

The invasion of the ctenophore Mnemiopsis leidyi (discussed in Section 12.4.1) affected the benthos by reducing both light and dissolved oxygen available to the seabed communities (through increased sedimentation5). Bivalve beds of Chamelea sp. and Gouldia sp. were displaced from deeper water and Mytilus galloprovincialis was completely eliminated at depths of 30 to 50 m. The subsequent reduction of M. leidyi numbers, as a result of predation by another invasive ctenophore, Beroë ovata, in the Black Sea resulted in a rapid increase in bivalve recruitment. This was in turn followed by a brief surge in numbers of the large predatory snail Rapana venosa as new prey resources became available. As the R. venosa population depleted its food resource, its population in turn collapsed and the benthic community became dominated by polychaete worms (Ref. 12.6).

Additional changes in ecology have been noted over the last ten years in relation to the southern region of the Russian coast of the Black Sea. For example, the once extensive areas of the seaweeds Phyllophora sp. and Cystoseira sp. have been reduced (Section 12.4.1). This has had significant implications for benthic ecology as the structurally complex red algae habitats were replaced by simpler, less diverse communities featuring fast growing pollution tolerant green algae (Ref. 12.6).

The nearshore Project Area runs through the Anapa Bank fishery protected zone. This is legally protected for a number of commercial fish species and is thought to be important for these species due to the benthic communities in the area. Anapa Bank is discussed in more detail in Section 12.4.8.1. In addition, the Utrish SPNA, which is protected for a number of macroalgal species, is located around 2 km at its closest point, from the Pipeline. This is also discussed in detail in Section 12.4.8.1.

Macrophytes

Macrophytes comprise macroalgae (seaweeds) and vascular plants (mainly seagrasses). They are key components of the marine ecosystem as primary producers, providing food to a wide variety of organisms either as living plant matter or detritus. Macrophytes also enrich water with

---

5 It has been shown, particularly in eutrophic waters that outbreaks of jellyfish predation can reduce or eliminate the grazing of zooplankton which results in an increased sedimentation of phytoplankton. This may cause severe oxygen depletion and release of nutrients from the anoxic sediment, creating a feedback system and exacerbating the effect (Ref. 12.16).
oxygen and take up dissolved organic matter, thus increasing the quality of coastal waters. Macrophyte stands serve as spawning grounds and shelter for many fishes and invertebrates.

Large perennial algae and grasses are thus habitat forming plants (edificators) in seabed communities that occupy significant areas on the continental shelf.

The marine flora of the Black Sea has been subject to significant changes in both biodiversity and abundance in the past few decades due to eutrophication. For example, a decrease in macrophyte diversity and reduction in extent of perennial algae, such as *Phyllophora* and *Cystoseira*, has been observed across most of the Black Sea together with an increase in the diversity and abundance of opportunistic, fast growing green algae that are more tolerant of eutrophic conditions.

On the Russian coast of the Black Sea, macrophytes include some 143 species of macroalgae (41 species of green, 29 species of brown and 73 species of red) and six species of vascular plants (including two seagrass species of the genus *Zostera*). Both species of the seagrass *Zostera (Zostera marina L.* and *Z. noltii)* have declined drastically in the Black Sea due to pollution (Ref. 12.19). By the 1980s, seagrass communities on the North Caucasian coast of the Black Sea had practically disappeared (Ref. 12.1) and significant seagrass beds are now confined to Taman Bay and Dinskoy Bay, on the shore of the Strait of Kerch (Afanasiev, Korpakova, 2008 in Ref. 12.1).

The important changes in the past few decades are an increase in the diversity and abundance of green algae and a simultaneous decrease of brown species. There have also been geographical shifts in species distributions as some species have spread to the North Caucasian coast from the other regions of the basin (Ref. 12.1).

Although green algae have become increasingly common as a result of the ecological changes, particularly eutrophication, in past decades, brown algae, such as *Cystoseira* spp., are still locally the most important group in that they form the most widely spread communities throughout the region despite falling abundance and diversity. The stock of *Cystoseira* along the North Caucasus shore has declined from almost 2 million tons to no more than 100 thousand tons in the past 30 years (Ref. 12.8). Nonetheless, it remains the most widely spread and richest macroalgal community along the coast (Ref. 12.1).

Red algae are the most taxonomically diverse group, but form less extensive communities. Large perennial species such as *Phyllophora crispa* (also known as *P. nervosa*) and *Coccotylus truncatus* (also known as *P.brodiae*) and others, form perennial communities either alone or in combination with *Cystoseira*. This is in contrast to the western Black Sea, where *Phyllophora* was historically the most important alga, forming fields of thousands of hectares.

The type of macroalgal community present is dependent to a large extent on depth. Large scale zonation across the entire photic zone can be observed (Ref. 12.1. and Ref. 12.4) as follows:

- **The Upper photic zone** comprises mosaics of red, green and brown algae, 0 to 2 m water depth;
- **The Mid photic zone** features primarily brown algae, particularly of *Cystoseira* spp., in water depths around 2 to 10 m. These species support a high diversity of macrofauna (Ref. 12.4). There is also a high diversity of red algae, present as epiphytes and understory
The density and extent of the *Cystoseira* zone is greatest at depths of 3 to 5 m. The distribution and density of this algal association has been considerably reduced in recent decades due to poor light penetration resulting from the effects of eutrophication and super-abundance of invasive ctenophores (Ref. 12.20); and

- **The Lower photic zone** (at depths below about 10 m) is characterised by a mosaic of different associations. Red algal species diversity is high although the recent ecological changes observed throughout the Black Sea have resulted in an increase in the presence of several species of green algae. The red alga *Phyllophora* is found at depths of 15 to 20 m though its extent and percentage cover have been considerably reduced in recent decades. In addition, there has been an increase in the presence of green algae at these depths, particularly of *Codium* spp. such that a *Phyllophora-Codium* association is recorded from many areas where *Phyllophora* alone was previously dominant.

**Macrozoobenthos**

Studies in the first half of the 20th century described the Black Sea benthic fauna as uniform and stable. The most common fauna were molluscs, polychaetes and crustaceans (Ref. 12.21). Since the mid-twentieth century, the benthos of the north-eastern Black Sea has undergone extensive changes. The first of these was the introduction, in 1947, of the large predatory snail *Rapana venosa* (also known as *R. thomaisiana*). This resulted in a significant reduction in oyster beds in the Black Sea although it did not have an impact on the distribution of other species or communities (Ref. 12.1). As discussed in Section 12.4.3.1, as *R.venosa* depleted its food resource, its population collapsed and the soft sediment benthic community became dominated by polychaete worms. Another non-native species, the ark shell *Anadara cornea* (also reported as *A. inaequivalvis* and *Cunearca cornea*) became well established in the 1980s. It was first noted in the Black Sea in 1981 near the Bulgarian coast and in 1986 along the Caucasian coast in the region of Tuapse-Shepsy. It has since become one of the dominant benthic species (Ref. 12.9).

However, the greatest changes to the Black Sea benthos started in the 1980s as a result of eutrophication and increases in water turbidity due to increased primary production. The first changes became obvious in the coastal communities of the shelf region to the east of the Crimea peninsula, with shifts in the abundance and biomass of bivalve mollusc species. The common bivalve *Chamelea gallina* was seen to be replaced by more siltation resistant species such as *Pollittapes petalina* and *Plagiocardium simile*. The small bivalve *Lucinella divarica*, found in abundances up to 6,500 individuals per square metre (ind./m²), totally vanished from these communities. Similar shifts to siltation tolerant bivalve species and the final disappearance of *Chamelea gallina* from sand biotopes at depths of 20 to 25 m were observed in the 1980s in surveys carried out between Anapa and Gelendzhik on the north-eastern coast (Nikolaenko, Povchun, 1993 in Ref. 12.1).

Further changes to benthic communities resulted from the explosive proliferation of the ctenophore *Mnemiopsis leidyi* in the late 1980s. As a voracious predator *M. leidyi* reduced zooplankton numbers resulting in further increases in primary production and sedimentation of particulate matter to the benthos (Ref. 12.1). This sharp increase of turbidity caused significant changes in the distribution of macroalgae because of the reduction in light availability. There was a thinning out of the seaweed *Cystoseira*, a decrease in the depth limit to which the
species was found and a general degradation of the deep-water vegetation at the southern part of the North Caucasian coast (Ref. 12.1). Another effect of the loss of algal cover was to make some mussels more available to predation by the snail *R. venosa*, resulting in an increase in the predator's numbers. The more recent arrival of a second invasive ctenophore, *Beroë ovata*, which is a predator of *M. leidyi*, has reversed this situation to some extent.

In the southern part of the North Caucasian coast, the reduction in oxygen levels over silty ground has given the bivalve invader *Anadara cornea* a competitive advantage over the previously dominant *Chamelea gallina*. By 1999 even the most developed *Chamelea gallina* communities in depths of 20-30 m had come to be dominated by the non-native species (Ref. 12.1).

Thus, the recent dynamics of the benthic communities of the North Caucasian coast of the Black Sea have been determined by the combined influence of two pelagic invaders *M. leidyi* and *B. ovata* combined with the influence of the carnivore invader *R. venosa* and the appearance of the bivalve competitor species *A. cornea* (Ref. 12.1).

Research carried out by the P.P. Shirshov Institute of Oceanology (summarised in Ref. 12.1) between 1999 and 2007 shows the communities of macrozoobenthos along the North Caucasian coast to be typical for the Black Sea. Coastal reefs and rocky ground to 12 m water depth have a dense cover of *Cystoseira* spp. and are occupied by a community dominated by the small bivalve *Mytilaster lineatus*, crustaceans, gastropod, various bryozoans and other encrusting animals. Permanent macrozoobenthos are absent from marginal littoral sandy areas (to 5 m) because of wave action and substrate instability. At depths between 7 and 20 m a community dominated by the bivalve *Chamelea gallina* is present. This has been replaced in deeper water (20 to 30 m) by *Anadara*, the edible mussel *Mytilus galloprovincialis* from approximately 35 to 50 m, and the horse mussel *Modiolula phaseolina* below 60 m. *Modiolula* beds may extend to the edge of the shelf although this would need to be confirmed by survey. A total of 120 benthic species have been recorded in the region.

### 12.4.3.2 Survey

#### Survey Area

The survey locations shown in Figure 12.4 make up the Survey Area discussed in this section for benthic communities. Information on the water depth and distance from shore of each station and survey methodologies is given in Table 12.1 and Table 12.3.

#### Survey Results

*Macrophytobenthos*

Phytothephos surveys were conducted in 2009 and 2011 (Figure 12.4) at the following locations:

- In May to June 2009, samples were collected at Stations 1 to 8s; and
- In August 2011, samples were collected at Stations 1 to 14c, and video footage was obtained from a transect survey between Stations 4c to 6c.
In shallow waters, macroalgae communities were characterised by a relatively low biomass and
the prevalence of green algae, primarily sea lettuce (*Ulva sp.*) and *Enteromorpha sp.* At 10 m
water depth, biomass was higher and *Cystoseira* was the dominant species. Over 15 m water
depth, *Codium, Phyllophora* and in some cases sea lettuce, were dominant, but macroalgal
biomass was lower than shallower areas (Ref. 12.1).

The following algal communities, generally on areas of bedrock and boulders, were observed:

- A *Cladophora dalmatica* community and a *Ceramium ciliatum / Padina pavonica* community
  in shallow waters at the coastline;
- A *Cystoseira crinata / Cystoseira barbata* community at a water depth of approximately
  10 m, succeeded by a *Cladostephus spongiosus / Corallina elongata* community; and
- A *Codium vermilara* community succession towards 20 m water depth.

No vascular plants, in particular seagrasses of the *Zostera* genus, were observed during the
2009 and 2011 surveys.

*Cladophora* communities had the greatest algal biomass. The biodiversity of macroalgae
increased with depth in the Survey Area (Figure 12.4). The highest algal diversity was noted at
the stations situated at a depth of 20 m (in *Cystoseira* and *Codium* communities) and the lowest
at stations in 0 m water depth.

---

6 It is currently considered that *Enteromorpha* is synonymous with *Ulva* and all the relevant species are now in the latter
   genus.

Isobaths
Two species of macroalgae that are listed in the Red Data Book of Krasnodar Krai were found during the survey (Figure 12.5). None were found on the IUCN Red List although the marine realm, and seaweeds in particular, are currently very poorly covered (Ref. 12.3). The brown algal species *Cladostephus spongiosus* and *Phyllophora crispa* were observed along the pipeline route alignment at Station 5. *Cladostephus spongiosus* and *Phyllophora crispa* both also occur in the Utrish SPNA (Ref. 12.4) which is discussed more fully in Section 12.4.8.1.

Table 12.7 presents the total number of species identified at the stations sampled and identifies the stations at which protected species were recorded.

**Table 12.7 Macroalgae Species Observed Listed in Red Data Book of Krasnodar Krai (August 2011)**

The August 2011 survey (Figure 12.4) shows that the communities of macroalgae were characterised by relatively low biomass, and a prevalence of the green algae Ulva (which now includes *Enteromorpha*, previously thought to be a separate species but now included in the
At depths less than 10 m, *Cystoseria* sp. was the most abundant and its biomass was higher in these shallow water areas. At deeper (over 15 m) locations the biomass of *Cystoseira* sp. was lower; *Codium*, *Phyllophora* and in some cases *Ulva* were the most dominant macroalgae (Ref. 12.1). The August 2011 survey observed 44 species of macroalgae (seven green, eight brown and 29 red). The maximum species diversity was observed at a depth of 20 m, at stations 3c and 11c (23 - 24 species) with the least diversity at stations 7c, 9c and 12c on the shoreline. The prevalence of brown algae over the green algae, the high population of pollution-intolerant species such as *Padina pavonica* and *Codium vermilara*, and the low number of epiphytes (algae that grow on other species) on *Cystoseira synusia*, indicate a low degree of eutrophication. The macroalgae community observed was similar in composition and biomass to that recorded in the 2009 surveys (Ref. 12.1).

Other surveys in the region, conducted to inform the Black Sea Commission ‘State of the Environment’ Report (Ref. 12.9), observed significant macroalgae populations attached to the shells of live molluscs on the soft bottom habitats of the Anapa region and Gelendzhik Bay. The area of this association between the algae and mollusc was large enough for it to be considered a significant contributor to primary production in soft sediment areas (Ref. 12.8).

**Macrozoobenthos**

Zoobenthos surveys were conducted at the following locations (Figure 12.4):

- During May-June, 2009 samples were collected at Stations 1 to 8s;
- In November 2010, samples were collected at Stations 1 to 4, 18, 19;
- In August 2011, samples were collected at Stations 1 to 14c and video footage was taken along a transect between Stations 4c to 6c; and
- In July 2013 51 stations were sampled by benthic grab and video.

The survey methodology is summarised in Figure 12.3. These locations comprise the Survey Area discussed in this section for zoobenthos.

Results of the 2009 surveys (spring-summer) found the epibenthic amphipod *Gammarus olivii* dominated both biomass and numbers at the shore stations 1S, 3S and 6S.

In 2009, at water depths of around 10 m (Stations 2S, 4S and 7S), the benthos was highly diverse comprising polychaetes, crustaceans, bivalves and gastropods. The substrate at these stations represented a mixture of sand with fine pebbles and shells. The distribution of organisms was uneven and species composition and abundance in repeated samples selected at a distance of 10 to 15 m water depth from each other varied considerably. The small polychaete *Staurocephalus rubrovittatus* and the soldier crab *Diogenes pugilator* were encountered at all stations.

Two samples were taken at stations 6S and 8S at a water depth of 15 m. Sediment composition at Station 6S comprised fine sands, while sediment composition at Station 8S comprised large stones and shells. Due to this difference in sediment type, the composition of the zoobenthic community at these stations differed significantly (Ref. 12.1).
The abundance and biomass of the dominant species recorded in the 2009 survey (less than 20 m water depth) is shown in Table 12.8. At Station 5S, the polychaete *Saccocirrus papillocercus* was the most abundant and at Station 8S three species (the polychaete worm *Melinna palmata*, the acorn barnacle *Balanus improvisus* and the crab *Macropipus arcuatus*) were dominant in number. A total of 15 species of macrozoobenthos were found in the Survey Area in 2009. None of these was a rare (i.e. IUCN Red List Categories 1 to 3, national or regional RDBs as endangered or critically endangered) or legally protected species.

Project surveys conducted in November 2010 extended the Survey Area along the Caucasian coast from near Kerch to near Gelendzhik. A community of *Spisula subtruncata* (reported as
Spisula triangula) was found at Station 1 near Kerch at a depth of 30 m over silty shelly ground (65% shell/gravel, 15%, 0.1 millimetres (mm)). This community was characterised by a relatively high richness of 35 species (13 polychaetes, eight bivalves, four gastropods, five crustaceans, two cnidarians, one nemertean, one turbellarian and one oligochaete). Average total biomass of the community at Station 1 was 334.27 g/m², average total abundance was 2,632 ind./m², and represented the highest biomass and abundance of any sample taken during the survey (Figure 12.6).

Further south, a Pitar rudis community was found at Stations 2 (near Anapa) and 19 (near Gelendzhik) at depths of 20 m and 34 m respectively. Bottom sediments at these stations comprised silty sand with shells. The bivalves Pitar and Chamelea are associated with a wide range of grounds, although they prefer sand deposits. The two stations showed some differences in richness and species composition. The northern site was richer (24 species as opposed to 15 in the south) and had a higher average biomass (86.0 g/m² compared to 4.55 g/m² in the south) and abundance (1,419 ind./m² compared to 394 ind./m² in the south). The northern sample comprised 10 species of polychaete, two bivalves, two gastropods, six crustaceans, two cnidarians, one nemertean and one phoronid. The southern sample comprised six polychaetes, two bivalves, four crustaceans, one nemertean, one cnidarian and one phoronid. It has been suggested that the impoverishment of the community near Gelendzhik Bay is due to anthropogenic effects (Ref. 12.1), though this site also had an appreciably finer sediment structure (56% particles 0.1 mm, cf. 35% in the northern, shallower sample).

The sample from deeper water (Station 4 at 58.8 m) was characterised by a community dominated by Plagiocardium papillosum and Modiolula phaseolina. The bottom sediments were silty sand (63% <0.1 mm) with shells, most of which showed evidence of gastropods predation (drill marks). The sample included seven polychaetes, two bivalves, one crustacean and one

---

7 Richness is distinct from diversity in that the former considers the total number of species in a sample, while measurements of diversity also factor in their relative abundance.
Echinoderm). Average total biomass of the community was 5.4 g/m² and average abundance 99 ind./m².

At depths greater than 80 m, the samples were dominated by the brittlestar *Amphiura stepanovi*. Here the seabed was characterised by fine clay ooze (86-99% < 0.01 mm), oxygen levels were lower and some H₂S was present. The average biomass of this type of community was low, from 1 to 2.3 g/m², total abundance ranged from 282 to 349 ind./m², and was composed of a large number of small-sized polychaetes.

In August 2011, the littoral communities of soft sediments and macroalgal thickets were surveyed at Station 4c, 5c and 6c using a video transect. On sandy grounds at 20 m isobath a *Pitar rudis* community was found, similar to that observed in 2010 but less rich (although high levels of spatial variability in species diversity and abundance is common in marine communities). It included six mollusc species, one polychaete and one bryozoan. The bivalves *Pitar rudis* and *Gouldia minima* dominated the assemblage both numerically and in terms of biomass. At station 14c, which had a reduced gravel component and relatively fine sediment (40% <0.1 mm), a high density of the small bivalve *Lucinella divaricata* was recorded (63 ind./m²). This community also included *Bittium reticulatum*, *Calyptraea chinensis*, *Mytilus galloprovincialis*, *Harmothoe reticulata* and *Scrupocellaria bertholletii* in low numbers.

The main macroalgae at 10 m water depth was *Cystoseira*, which supported a faunal community comprising 35 species of macrozoobenthos. The bivalve *Mytilaster lineatus* and the snail *Bittium reticulatum* together dominated the biomass of this community (15.48 g/m² and 4.04 g/m² respectively). *M. lineatus* is one of the main components of seaweed thickets throughout the Black Sea due to its high settlement density and resistance to pollution (Ref. 12.1). This is of wider significance because *M. lineatus* is therefore the main provider of natural bio-filtration along the Black Sea coast and can be present in high densities. The maximum abundance of *M. lineatus* observed in this survey was 2,826 ind./m² (average 891 ind./m²). The fouling polychaete *Spirorbis pusilla* was also common on algal thalli and *M. lineatus* shells in this community, and is considered a dominant species. The dominance of *M. lineatus* is consistent with historical data collected from 1999 to 2007 by the P.P. Shirshov Institute of Oceanology (summarised in Ref. 12.1) along the North Caucasian coast.

At a depth of 20 m, the main thicket forming algae were *Phyllophora* and *Codium*. The associated faunal community includes 34 species (11 molluscs, 11 crustaceans, 7 polychaetes, 4 bryozoans and 1 hydroid). Again, *M. lineatus* dominated the biomass (10.35–28g/m²). The snail *Bittium reticulatum* was numerically dominant (910–1,781 ind./m²). The gastropods *Tricilia pulla* and *Rissoa splendida* were present in lower numbers, but in the same order of magnitude as *M. lineatus*. The most significant encrusting animals were the bryozoan *Cryptosula pallasiana* (reported as *Lepralia pallasiana*) and *Spirorbis pusilla*. The high diversity of macrofauna within the algal beds observed in this survey are consistent with other data sources located near Utrish (around 2 km from the Project Area) located along the Caucasian coast (Ref. 12.1 and Ref. 12.4).

In July 2013 a further benthic survey of the coastal area (Figure 12.4), including locations of the proposed seabed intervention work, was carried out. Of the 51 target stations, 10 were in shallow waters (<20 m) where grab samples could not be collected because the seabed comprised mainly bedrock and boulder. There is however, Remotely Operated Vehicle (ROV)
video and stills data for all stations, which have been used to identify the benthic communities present.

There was considerable variability in both the number of individuals and the number of benthic species. Grab samples contained between 6 and 397 individuals, and between 2 and 14 different species.

The distribution of invertebrate marine fauna is often correlated with the nature of the substratum and so abundance and number of species has been analysed by sediment type (Table 12.9). This analysis shows that the highest variability in abundance occurred in muddy habitats. The fact that the maximum abundance (397 individuals) is far higher than the average abundance of 66 individuals indicates the highly discontinuous and patchy distribution of fauna typical of marine sediments.

* Sediment type was classified using the FOLK sediment triangle on the basis of sediment particle size analysis data (Ref. 12.22)

Multivariate analysis of the benthic communities, using PRIMER, identified broad groups that were grouped largely by sediment type with some influence of depth (Figure 12.7). Muddy stations cluster together showing a similar species composition, although a number of samples from between 90 and 112 m are included within a separate group (circled in red), which may reflect changes in species distribution in response to lower levels of oxygen in deeper sites, and/or in response to slight variations in the sediment composition of muds between stations.
There was only one sandy station sampled during the 2013 survey so the species present may
not be representative. The sample was characterised by burrowing organisms including the
bivalves *Gouldia minima* and *Chamelea gallina* and amphipods of the family *Corophiidae*. The
lancelet, *Branchiostoma lanceolatum*, a species typically found only in sandy sediments, was
also present (Table 12.10).

The muddy sediments of the Survey Area support communities dominated by bivalves such as *Modiolula phaseolina* and *Parvicardium simile* and by a number of polychaete species (Table 12.13). There is, however, considerable variability in total abundance between stations, as shown in Table 12.9, and abundance by species is similarly variable between stations.

The sediment particle size and biological community data (Figure 12.7) have been analysed together to determine the nature of the benthic habitats in the survey area. Whilst EUNIS biotope codes are not presented for habitats the data has been analysed using similar methods to determine habitat types in the Survey Area (Ref. 12.23). Where a grab sample data was not available, e.g. for the rocky areas, the habitat has been identified on the basis of video and stills images and data from previous diver surveys. A total of nine habitat types in the survey area have been identified. These habitat types are clearly related to depth and nature of the seabed as described below and in Table 12.14 and their distribution is shown in Figure 12.8.

At all stations sampled between 3 and 20 m the seabed was uneven bedrock and boulders with some small patches of sediments between boulders or in crevices in the bedrock. These areas were dominated by algal communities and the depth based zonation of algal species seen in previous surveys was observed.

In the shallower regions, between 3.9 and 11.0 m, there were dense algal communities, with 90 to 100% algal cover, dominated by Cystoseira spp. In water depths from approximately 12 to 19 m, samples were also dominated by rocky seabed, but with less dense coverage of algae, predominantly Codium vermilara. Diver recordings in previous years’ surveys indicate that these algal habitats support a high abundance of the mussel Mytilaster lineatus which is found attached to Cystoseira thalli and the small needle whelk Bittium reticulatum.

In water depths between 19 and 27 m a variety of sediment types are found including sand, mixed and coarse sediments. There was no bedrock observed in any of the samples in water depths greater than 20 m. The communities in these areas are dominated by infaunal organisms, predominantly burrowing bivalves such as Gouldia minima and Chamelea gallina and infaunal polychaetes including Spio filicornis.

Beyond 33 m water depth the seabed consists of muddy sediments which support communities of burrowing bivalves and infaunal polychaetes. At one station, Station 19, dense patches of large ascidians were observed on the video footage. The number of species per grab sample is not particularly high, between 4 and 6 species, but abundance is highly variable with between 6 and 397 individuals recorded. These communities, as shown in Figure 12.14, were found at all stations sampled between 33 and 113 m.

Muddy sediments were also found at stations in much deeper water, between 365 and 573 m, but at these depths the sediments are completely devoid of fauna because conditions are anoxic below about 150 to 200 m water depth.

**12.4.3.3 Summary**

In shallow waters, where there is rock, cobbles or pebbles for attachment, the benthos is characterised by macroalgal communities. There is distinct zonation of algal communities in the Survey Area, with distinct macrophyte communities at different depth ranges.

In shallow waters (up to 2 to 3 m depth) macroalgae communities characterised by a relatively low diversity and biomass were observed. This includes a community of *Cladophora dalmatica* and an association of *Ceramium ciliatum* and *Padina pavonica*. There was also a prevalence of green algae, primarily sea lettuce (*Ulva sp.*) and *Enteromorpha sp.* In the mid photic zone, from about 3 to 10 m algal communities dominated by large structural brown algae dominate. In particular associations of *Cystoseira* spp. are found, succeeded by a *Cladostephus spongiosus* and *Corallina elongata* as depth increases. At depths over approximately 10 m, communities of *Phyllophora* and *Codium vermilara* are observed. The highest diversity of algae is found in the mid-photonic zone and *Cystoseira* communities also support a high diversity of macrofauna and considerable biomass of the mussel *Mytilaster lineatus* in some areas.

Species diversity of macroalgae was greater in the *Cystoseira* and *Codium* communities at 20 m water depth. Abundance and biomass was greatest at 10 m water depth with *Cystoseira* as the most abundant species observed. This is consistent with the historical data of bathymetric heterogeneity along the Caucasian coast of the Black Sea, in which the Survey Area is located (Ref. 12.1 and 12.4). The data from the 2009 and 2011 surveys, which were carried out at different times of the year, indicate that this general distribution pattern is not subject to seasonal changes.

Two species of macroalgae that are listed in the Red Data Book of Krasnodar Krai were found during the 2011 survey. The brown algal species *Cladostephus spongiosus* and *Phyllophora crispa* were observed along the nominal pipeline route alignment at Station 5c.

Macroalgae also supported animal communities, particularly of bivalve molluscs, but also polychaetes and crustaceans. The macrozoobenthic communities of soft sediments are largely determined by the sediment type and comprise a number of infaunal animals, particularly bivalves and polychaetes but also crustaceans, gastropods and echinoderms. There were no macrofaunal species of commercial or conservation importance recorded in the Survey Area.

**12.4.4 Deep Sea Benthic Habitats**

The deep waters of the Black Sea have recently been shown to support significant biogenic structures in some areas (Ref. 12.7). At certain sites on the northwest Black Sea shelf, carbonate accumulation has formed reef towers structures that can reach several metres in height (Ref. 12.7). These towers may release methane bubbles so that they superficially resemble hydrothermal vent chimneys found on tectonic margins, though they have no associated multicellular life and are characterised by the presence of morphologically and phylogenetically distinct unicellular communities.

Sidescan and ROV data from the deep water parts of the pipeline route have been examined in detail to ascertain the nature of the deep seabed and to identify, as far as possible, the
presence of deep sea microbial reefs or other structures (Ref. 12.5). A summary of the findings is presented below but the full report can be found in Appendix 7.1: Abyssal Plain Report.

Small carbonate mounds related to fluid seepage can be identified at a few locations along the Russian shelf edge. On sidescan data, they are hard targets with a typical irregular ‘knobby’ appearance. Most cannot be identified on bathymetric data, partly because they are small, low relief features, but also because their occurrence is masked by the typically steep terrain in which they occur. Carbonate mounds occur in the relatively narrow depth band between about 110 and 140 m. This suggests that in addition to fluid seepage, the location of these features is constrained by other factors, most likely the low level of oxygen in the stratified water column. There is no suggestion that these are biogenic structures.

The lower Russian continental slope and the contiguous abyssal plain are generally relatively smooth with a gradient that gradually decreases until the slope merges with the plain. No significant bacterial communities, such as cold seep communities with associated macrofauna, microbial mats or microbial reefs were encountered anywhere along the pipeline route (Ref. 12.5).

12.4.5 Fish

12.4.5.1 Background and Literature Review

A long term data set in the north-eastern Black Sea has been collected by the Azov Fish Industry Research Institute between 2003 and 2011 and is summarised in Ref. 12.1. This information has been used to support this section.

In recent years (the last two decades), 103 species of fish⁸ have been recorded from the Black Sea shelf of the Russian Federation (Zaika 2000 in Ref. 12.1). These are divided into several groups according to their lifestyle and biogeographic origin:

- Anadromous species that feed at sea and breed in freshwater include sturgeons (Huso huso, Acipenser gueldenstadtii, A.persicus, A.sturio and A.stallatus), Sea of Azov-Black Sea herrings or shad (Alosa pontica) and Black Sea salmon-trout (Salmo labrax);
- Semi-anadromous fish only occur in the least saline areas of the sea and include the Batumi shemaya (Alburnus chalcoides) and vimba (Vimba vimba);
- Two freshwater species occasionally enter the sea (goldfish Crassius auratus and mosquito fish Gambusia affinis⁹), but are essentially non-marine;
- True brackish-water species reside in low salinity basins and estuaries. Some are euryhaline (tolerant of a wide range of salinity). This group includes the stickleback Pungitius platygaster, and several goby species;

---

⁸ This number must be viewed as approximate due to significant uncertainty regarding the taxonomic status of some species.
⁹ Introduced from North America to eradicate malaria mosquitoes in the region
• The group of Boreal Atlantic relics is represented by species that prefer colder water, including dogfish (Squalus acanthas), sprat (Sprattus sprattus), and whiting (Merlangius merlangus); and

• The most numerous group of fish are the ‘thermophillic’ species, generally of Mediterranean origin, that prefer the warm surface layers of the sea. This includes pelagic species such as sardine (Sardina pilchardus), garfish (Belone belone) and horse-mackerel (Trachurus mediterraneus); demersal species such as bogue (Boops boops), drum (Sciaena umbria) and several species of wrasse; benthic species such as stingray (Dasyatis pastinaca), rockling (Gaidropsarus mediterraneus) and weever (Trachinus draco) and cryptic species such as seahorse (Hippocampus guttulatus), clingfish (Lepadogaster spp.) and pipefish (Syngnathus spp.).

In general, water shallower than 25 m is characterised by the greatest species diversity, particularly over rocky grounds. Numerous species of fish, including some of commercial interest, (refer to Chapter 14 Socio-Economics for more discussion on commercial fisheries) use the vegetated shallow waters where thickets of Cystoseira provide shelter and cover for spawning. These rocky bottoms are not subject to fish trawling. Areas of sandy substrate appear to support fewer species (Ref. 12.1). The number of species decreases with the increase of the depth with only 20 species recorded below 50 m. This pattern of distribution also reflects the dominance of Mediterranean thermophillic species that prefer the well-warmed surface layers of the sea (Azov Fish Industry Research Institute in Ref. 12.1).

Eutrophication, combined with invasions of non-native species, discussed in Section 12.4.1, and significant over-fishing in recent decades have caused changes in offshore pelagic fish populations (Ref. 12.8). Sprat, horse mackerel, and anchovy (Engraulis encrasicolus) populations all collapsed in the 1990s though there have been some recent signs of recovery. Populations of larger pelagic fish such as tuna (Thunnus thynnus), swordfish (Xiphias gladius), and mackerel (Scomber colias and S.scombrus) have also substantially declined (Ref. 12.8).

There are a number of fish species caught commercially including sprat, anchovy, horse mackerel, whiting, goatfish and some mullet. However, total fisheries catch is dominated (over 90% of total biomass) by sprat and anchovy (Azov Fish Industry Research Institute in Ref. 12.1). The distribution of many of the commercial fish species is highly seasonal as populations migrate between spawning and feeding grounds. Anchovy overwinter in the Anapa region and sprat and horse mackerel migrate here for feeding, mostly during the warmer spring and summer months (Ref. 12.1). The regional migrations of these species are shown in Figure 12.9:

• Anchovy feed in the area shown during October and November;

• Sprat spawn in mid-March to early April and then migrate to the coastal zone for feeding until late-spring / early summer; and

• Horse mackerel feed near the coast during the summer months.

---

10 In this context, cryptic species are those that spend most of their time hidden in weeds, under stones etc.
• Several species of fish of conservation importance have been observed from the Russian Black Sea coastline caught in fixed gear at commercial fishing stations\(^\text{11}\) (Table 12.15). Of particular note is the presence of Russian sturgeon (*Acipenser gueldenstaedtii*) and stellate sturgeon (*Acipenser stellatus*). These sturgeon species are listed by IUCN as critically endangered (Ref. 12.9), though they are not included in the Red Books of either the Russian Federation (RDBRF) or Krasnodar Krai (RDBKK). They were only recorded in single cases, when immature fish were caught (Azov Fish Industry Research Institute in Ref. 12.1) but given their naturally wide ranging habit, it is possible that sturgeon might be present, albeit as individuals, in the Survey Area.

Client
Russian sturgeon are very large slow growing anadromous fish, generally taking ten or more years to mature to a size that may exceed 2 m and 100 kg (Ref. 12.26). Adults dwell at depths from 20 to 100 m, exhibiting complicated patterns of spring and autumn runs such that adults and juvenile ranges overlap both spatially and temporally. They feed on a variety of benthic invertebrates and fish. The Russian sturgeon is now very rare in the Black Sea basin where almost all of the species’ spawning sites have been lost due to dam construction, except in the lower Danube where some spawning still exists. The last natural population still migrates up the Danube and the Rioni (last recorded in Rioni in 1999), where the sturgeons are heavily overfished and poached (Ref. 12.26). It is estimated that the species’ wild native population has undergone a massive population decline of over 90% in the past three generations.

Stellate sturgeon is a smaller species, generally only less than 10 kg though 50 kg specimens are known (Ref. 12.37). It is less benthic in habit than other sturgeon species and may be encountered at the surface on occasion. Though fish may spawn throughout the year (where spawning sites are available), there are two peak spawning runs in spring and autumn. It too has suffered drastic population declines across its range, due to a combination of habitat loss, overfishing and poaching. In addition, its semi-pelagic habit meant that the stellate sturgeon was more affected by the Mnemiosps leidyi outbreak (discussed earlier) than other sturgeon species (Ref. 12.3).

Both these sturgeon species were only found as single juvenile specimens in fixed nets at the four commercial observation stations. The Fishing Rules for the Sea of Azov-Black Sea commercial fishing region prohibit the catching of all sturgeon species. Sturgeons also fall within the scope of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) which prohibits trade and movement across national borders of both living sturgeon and sturgeon products (notably caviar) (Ref. 12.3).

Thornback rays are demersal coastal species that inhabits a variety of substrates, including mud, sand, shingle, gravel and rocky areas, mainly recorded at water depths up to 50 m (Ref. 12.1). Young and juveniles predominantly eat small crustaceans, such as shrimps, mysids, amphipods and small crabs. Larger specimens prey on larger crustaceans, including prawns and crabs and will also consume fish. Because it is an important component of many European fisheries, and its numbers are declining, it is classed by the IUCN as near threatened (Ref. 12.3). Thornback rays are non-migratory and in Russian waters are distributed from Novorossiysk to Adler, approximately 50 km to the south of the Pipeline route (Ref. 12.1).

Black Sea salmon spawns in all large mountain rivers all along the Caucasus coast. Because of dams on most of the Black Sea basin’s rivers, most returning adults are unable to reach spawning sites and the anadromous population is now rare. The sea period of the lifecycle has been poorly studied. Because the species has been impacted by the construction of dams (mostly more than three generations ago), it has now considered a stable, albeit rare, population and does not qualify for IUCN Threatened or Near Threatened status despite its scarcity. This species has been observed in fixed stations in the four commercial observation stations.

Long snouted seahorse, currently listed as data deficient by the IUCN (formerly considered vulnerable), were observed at depths of 1 to 30 m throughout the survey area. Seahorses live
Long-snouted seahorses were noted throughout at depths of 1 to 30 m. They breed between April and October, with the timing being dependent on water temperature (Ref. 12.24). Long-snouted seahorses have low dispersal and limited migration (Ref. 12.25). This reduces their ability to colonize new areas, recolonize old ones, and in addition reduces their ability to move when habitat becomes unfavourable. However, the long snouted seahorse matures at an early age, has rapid growth rates, and a short generation time which may assist populations to recover as effects of disturbance cease. Seahorses have been significantly exploited by manufacturers of souvenir products and were initially included in the Red Data Book of the Krasnodar Krai as a protective measure. However, the population of long snouted seahorse in the Black Sea has increased significantly and it was removed from this Red Data Book. It remains on a list of species that are prohibited for catching by the Fishing Rules for the Sea of Azov-Black Sea commercial fishing region.

The corb is a solitary demersal fish usually found over sandy or muddy ground as well as inhabiting seagrass beds. It feeds on a wide variety of invertebrates. Spawning usually occurs from April to June (Ref. 12.38). During the surveys it was recorded at depths of 10 to 50 m but infrequently. Until recent years it has been a preferred object of spear fishing and is now included in the Red Data Book of the Krasnodar Krai and catching it is prohibited.

Tub gurnards are widely in the areas of Bolshoy Utrish, Novorossiysk, Gelendzhik and Arkhipo-Osipovka at depths of 10 to 50 m. It is a benthic species usually inhabiting sand, muddy sand or gravel bottoms where it feeds on a variety of fish and invertebrate prey. The largest of the gurnards, it may grow to 6 kg and live for 14 years (Ref. 12.9). Tub gurnards have been heavily exploited for the manufacturer of souvenirs and by underwater hunters. The pollution of the marine environment as well as illegal fishing has made this species quite rare in the last decade. This species has been entered into the Red Data Books of the Russian Federation and the Krasnodar Territory to ensure its strict protection.

Leaping mullet are native to the Eastern Atlantic, Mediterranean and Black Seas, though they have been introduced to the Caspian. They inhabit coastal waters, sometimes in lagoons and estuaries. The adults are herbivorous though the juveniles feed on zooplankton until about 3 cm, then on benthic invertebrates until 5 cm. The adults feed on algae and vegetal detritus (Ref. 12.38). They reproduce in summer and the eggs are pelagic. The species is of some commercial interest, being consumed fresh, smoked and frozen, as well as for its roe.

Bluefish are a large shoaling pelagic predator. It is a voracious feeder, and has been noted to destroy sardine, anchovy and horse mackerel shoals in excess of its feeding requirements (Ref. 12.11). It is known to spawn and feed in the Survey Area and fingerlings are relatively abundant within 30 km of the coast (Ref. 12.1). Juveniles and adult individuals spend the winter period offshore, outside the Russian sector of the Black Sea.

The presence of sardine (Sardina pilchardus) is also noteworthy; although it is not protected it is rare in this area. The sardine is a well-known shoaling pelagic species of considerable economic importance globally, though less so in Russian sector of the Black Sea where it is not common. It shows slight diurnal vertical migrations, moving slightly deeper by day (Ref. 12.25). Sardines feed mainly on planktonic crustaceans. They spawn over a wide area in June to
August. This species was not caught in fixed stations in the four commercial observation stations.

Other notable species are Black Sea turbot (*Scophthalmus maeoticus*) and sprat that form the basis of commercial fisheries, and are the focus of a fisheries protection zone at Anapa Bank, which was initially set up as a protected breeding ground for the former.

The Black Sea turbot can reach 85 cm and 15 kg and attain sexual maturity at the age of seven to ten years. In the summer, they keep close to the shore, where they spawn and feed. Their diet consists of small fish and crustaceans. Annual spawning occurs from May to July. The roe is pelagic and fertility ranges from 3 to 13 million eggs. Black Sea turbot do not undertake long migrations along the coast and only swim locally to feed and reproduce. The North Caucasus and Anapa schools swim in the north-eastern part of the Black Sea (Ref. 12.1).

Sprat are wide ranging pelagic planktivores. The main part of the stock spawns from October until March when the shoals are scattered throughout the central Black Sea. Once the fish have spawned (from mid-March to mid-June) they migrate to feeding grounds over the shelf, usually coinciding with the warming of the surface layers and formation of the stable thermal stratification. During this period, sprat form intensive concentrations at depths between 20 and 80 m on the shelf of the Kerch-Taman area (the Panagiya Cape to the Utrish Cape). Sprat clusters remain in coastal shelf areas until early-October, when they disperse to spawn.

**12.4.5.2 Survey**

**Survey Area**

The survey locations given in Figure 12.10 make up the Survey Area discussed in this section for fish. Information on the water depth, distance from shore and survey methodologies is given in Table 12.1 and Table 12.3.

Fish surveys were conducted using fish trawls in November 2010 and June 2011 at a range of depths (15 to 98 m) and gillnet surveys in less than 20 m water depth, were conducted in June 2011 (Figure 12.10) as follows:

- Nine fish trawl transects (Trawl stations 1 to 9) in November 2010;
- Ten fish trawl transects (Trawl stations 1 to 10) in June 2011; and
- Four gillnet surveys in shallow waters (less than 20 m depth) in June 2011.

Survey Results

In November 2010 a total of 15 fish species were found in trawls. Table 12.16 shows the total biomass of fish caught in the trawls and the relative percentages of the main species recorded in trawls in November 2010. The biomass of fish was greatest in the trawls from shallower waters (Trawls 1, 2 and 3 up to 30 m depth) although Trawl 9 biomass, from 28 m, was low. Catches in waters between around 20 and 30 m (Trawl 1, 2, 3 and 9) were dominated by anchovy. In deeper waters (over 30 m), Sprat recorded the highest values for abundance and biomass. Horse mackerel and whiting were also abundant in deeper water trawls (over 60 m water depth).

As with the November 2010 trawls the greatest diversity of species observed in 2011 was found in shallow waters. Spurdog (*Squalus acanthias*), sprat, anchovy and Black Sea turbot (*Scophthalmus maeoticus*) and flounder (*Platichthys flesus*) were only found below 25 m. At water depths between 50 to 85 m, species composition was the poorest with sprat, anchovy, whiting (*Merlangius merlangus*), Mediterranean horse mackerel, Black Sea turbot, spurdog and the thornback ray recorded (Ref. 12.1). This was also observed by the Azov Fish Industry Research Institute in Ref. 12.1, which recorded a decrease in species abundance with increasing depth and is also reported elsewhere (Ref. 12.11). The lower species diversity in deeper waters was probably due to the absence of Mediterranean species that prefer warm surface waters and comprise the largest group of the Black Sea’s fish fauna. In addition, the anoxic conditions which occur in deeper water (at depths below about 150 m) restrict the vertical distribution of organisms, including bottom-living fish (Ref. 12.8).

Several species of commercially important fish were recorded from the November 2010 and June 2011 trawls, particularly sprat and anchovy.

The species of conservation importance caught during the surveys in November 2010 and June 2011 were the leaping mullet (*Liza saliens*) and the thornback ray (*Raja clavata*).

### 12.4.5.3 Summary

The Russian coastal area of the Black Sea supports around 103 species, dominated by Mediterranean thermophilic fish. The highest diversity of fish is found in shallow waters, below 25 to 30 m, in association with *Cystoseira* thickets that provide important fish habitat. The number of fish species declines with increasing water depth.

Trawl and gillnet data confirmed the presence of several commercially important fish, particularly, anchovy and sprat, in the Survey Area. The shallow waters of the coastal region are used by many of these species as feeding grounds.

Two species of fish of conservation importance, the thornback ray and the leaping grey mullet were recorded from trawls and gillnets in the Survey Area. A further seven protected species, whilst not observed in the Survey Area, have been recorded from nearby locations (Table 12.17).
12.4.6  Seabirds

12.4.6.1  Background and Literature Review

The Black Sea lies within the Mediterranean-Black Sea Flyway, and the Caucasian coast forms an important migration route (the Trans-Caucasian Flyway) within this larger zone. Owing to its geographic location and varied landscape the region is ornithologically important (Ref. 12.28). The habitat diversity and climate create conditions suitable for the nesting, migration and wintering for thousands of seabirds. During seasonal migrations the whole Black Sea region carries millions of birds from their European nesting sites to their wintering areas (Ref. 12.28). There are two periods for migration in the north-eastern Black Sea region; one during the spring (mid-February to early-June) and one in the autumn (early-August to end-November) (Ref. 12.1).

The available information on wintering seabirds in the north eastern Black Sea is relatively scarce (Ref. 12.1). Mediterranean shearwaters (Puffinus yelkouan), cormorants (Phalacrocorax carbo), Arctic skua (Stercorarius parasiticus) and several species of gull overwinter along the Caucasian coast, but there are no known large permanent colonies of seabirds in the Survey Area. Other birds known to winter in the area of the North Caucasian coast of the Black Sea includes loons and grebes. In general, there is no large grouping of seabirds on the sea surface in the winter (Ref. 12.1).

The most significant seabird habitats in the Black Sea are found on the north Coast from the Danube Delta in Romania to the Kerch Strait (north of Anapa). Chapter 11 Terrestrial Ecology contains more detail on terrestrial habitats for nesting, migrating and overwintering seabirds along the Black Sea coast of Russia.

The seabird species which are known to occur at different times of the year along the north-eastern part of the Black Sea and the sea coast of the Gelendzhik area (60 km south of the Project Area) can be loosely divided into the Groups shown in Table 12.18.

### Group Information

<table>
<thead>
<tr>
<th>Group</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pelecaniformes e.g. pelicans and cormorants</td>
<td>They are typical water birds, but they do use the land. They nest in colonies in inland waters and on the coast. The nearest known nesting areas are the south-eastern part of the Sea of Azov. They are present in the region generally from November to April. They feed exclusively on fish.</td>
</tr>
<tr>
<td>Geese</td>
<td>Geese are only found on migrations in the region from late October to mid-November and early March to mid-April. They nest on the ground in open habitats. They are exclusively herbivorous birds, feeding mostly on land.</td>
</tr>
<tr>
<td>Swans</td>
<td>They nest on inland waters, but during migration and in winter they can be observed on marine waters. In the region they may occur during migration from September to late April, but they are most common in winter. The closest nesting site is the Sea of Azov. They are herbivorous.</td>
</tr>
<tr>
<td>Dabbling ducks</td>
<td>Typically freshwater. They nest on the ground along banks of water courses. They occur during migration and wintering from late August to late May. They feed on phytoplankton and zooplankton and sometimes eat larger invertebrates - crickets, etc.</td>
</tr>
<tr>
<td>Diving and sea ducks</td>
<td>They nest primarily along the freshwater shores. In the region they can be observed during migration and, more rarely, during wintering from September to May. They feed mainly on zooplankton, larger invertebrates (crustaceans, molluscs, etc.), sometimes eat small fish.</td>
</tr>
<tr>
<td>Coot</td>
<td>Coot nest in fresh and brackish waters or sea bays with dense thickets of rush, reeds and other macrophytes. They are known to nest in the Sea of Azov area. In the region they are likely to be observed throughout the year, but mainly from September to May. Feed mainly on plant foods but can sometimes eat medium-sized invertebrates and small fish.</td>
</tr>
<tr>
<td>Raptors</td>
<td>They are associated with water due to their diet of fish. Raptors nest on large trees, usually not further than 1 km from water. They are most likely to be observed in the region in the autumn-winter period.</td>
</tr>
<tr>
<td>Waders</td>
<td>Ground-nesting birds that nest near water. They feed on small invertebrates In the described area, most species can occur only during the migrations - from September to late November and from early March to May.</td>
</tr>
</tbody>
</table>

*Continued...*
<table>
<thead>
<tr>
<th>Group</th>
<th>Information</th>
</tr>

### 12.4.6.2 Survey

#### Survey Area

The survey locations given in Figure 12.11 comprise the Survey Area discussed in this section for seabirds. Information on the water depth, distance from shore and survey methodologies is given in Table 12.1 and in Table 12.3.

Seabird transects were conducted in November 2010, April to June 2011 and in July 2013. Figure 12.11 shows the locations of the 2010 and 2011 surveys. Figure 12.12 shows the locations of the 2013 survey. The surveys were conducted at the following locations:

- Ten transects in November 2010;
- Nine transects in November 2010 (during fish trawls);
- Twelve transects in June 2011; and
- In July 2013; 38 transects and 51 stations in coastal region were sampled.

Survey Results

During November 2010, 24 species of seabird were observed. The Charadriiformes (which includes gulls, skuas, terns, waders and auks) were the most abundant group of seabirds (Table 12.19). Migrations of Charadriiformes in the region take place during spring from March to early June, and in autumn from August to November (Ref. 12.1). The most abundant species that were observed in transects during 2010 were the Mediterranean shearwater (Puffinus yelkouan), and the Caspian gull (Larus cachinnans), Table 12.19).

In April 2011, a total of 23 seabird species were recorded during transects (Figure 12.11). Large groups of migratory species were observed, such as grebes, which were more abundant than all other species, especially in coastal areas (Ref. 12.1). Grebes are freshwater species which may use coastal areas as a feeding ground. Groups of the black-throated diver (also known as a black-throated or Artic loon, Gavia arctica) were also detected. The common cormorant is a typical species for the Black Sea and 110 individuals were recorded. Cormorants were generally found near the coast of Novorossiysk and to the lesser extent near Gelendzhik (south of the Survey Area) (Ref. 12.1). The sandwich tern (Sterna sandvicensis), Caspian gull and lesser black-backed gull (Larus fuscus) were also abundant in transects throughout the entire Survey Area (Table 12.19).

Charadriiformes were the most commonly observed group of birds during offshore transects. The majority of birds observed were concentrated near the coast (no more than 20 km from land). In offshore areas of the Survey Area (Figure 12.11), the number of seabird sightings was reduced (Ref. 12.1).

The full list of species observed during transects for all three years is shown in Table 12.19.

* Ecological status based on published data Ref. 12.29.
** Some of the Black sea population winters locally, though mostly in the Mediterranean.
† There is significant taxonomic confusion regarding European shearwaters; for the purposes of this report, all have been reported as *P. yelkouan*, which is currently considered the only species that regularly occurs in the Black Sea.

In November 2010, the highest numbers of birds were observed at coastal transects (Figure 12.13) (Ref. 12.1). This is similar to the results in April 2011 although more migratory species were observed in April 2011. The density of birds decreases with increasing distance from the shore. At around 40 km offshore, no birds were observed during transects (Ref. 12.1). The
abundance (absolute number) of seabirds in the Survey Area is shown in Figure 12.13. Some species were not observed during transects but were seen during sailing time to and from stations; the locations of these species have also been recorded in Figure 12.13 as “data out of transects”.

Figure 12.13 Abundance of Birds Recorded During Surveys in November 2010

During the July 2013 surveys a total of 13 species were observed. However, two seabird species, the Mediterranean shearwater (*Puffinus yelkouan*) and the Caspian gull (*Larus cachinnans*), dominated seabird numbers (Table 12.19) together accounting for over 98% of transect observations and over 96% of sightings from fixed stations. The abundance of birds was variable throughout the Survey Area (Figure 12.14).

The Mediterranean shearwater was observed throughout the survey area as individual specimens and in small groups of 5 to 10 birds. There were very high densities, up to a maximum of 108 individuals/km², mostly in areas away from the very near shore (within a kilometre or two), such as close to the shelf break. The average density of Mediterranean shearwaters across the survey area was 11.5 observations/km² with a maximum of 108 individuals/km². The average density of the Caspian gull was 6.9 observations/km² with a maximum of 30/km².

The data from the three surveys reflects the seasonality in the abundance of some bird species in the survey area. In particular, the little gull, sandwich tern, great crested grebe and common
cormorant were observed at much higher densities in April compared to July and November although some differences may be due to normal interannual variability.

**Figure 12.14 Abundance of Birds Recorded at Stations During July 2013 Survey**

Three species observed offshore are of conservation interest (Table 12.20). These were the only species recorded during offshore surveys that are listed in the Russian Federation (RDBRF) or Krasnodar Red Data Books (RDBKK) or listed as 'vulnerable' or above on the IUCN Red List. The locations of the Red Data Book species observed during 2010 and 2011 surveys are given in Figure 12.15.

1IUCN: LC=Least Concern; NT=Near threatened; VU=Vulnerable; EN=Endangered; CR= Critically endangered; EW=Extinct in the wild; EX=Extinct 2Red Data Books: 2= vulnerable species and subspecies declining in number; 3=rare species and subspecies.

Figure 12.15 Occurrence of Red Data Book of Russia Bird Species Observed

In the July 2013 surveys the only protected species observed was the Mediterranean shearwater, *Puffinus yelkouan* which was present in high abundance, as many as 200 observations at some stations (Fig. 12.16).
An additional protected species that is likely to occur in the Survey Area (Ref. 12.1), but was not directly observed in surveys, is the gull-billed tern (*Gelochelidon nilotica*). This species is in both the Russian and Krasnodar Red Data Books. Notes on these species are provided in Section 12.4.6.2.

The black-throated diver or Arctic loon (*Gavia arctica*) is strongly migratory, breeding in isolated solitary pairs in deep cold lakes or inlets generally at high latitudes from April onwards. When migrating, divers often form flocks of around 50 individuals which then disperse, so that wintering birds generally occur singly, in pairs or small flocks (Ref. 12.29). However, because their diet is predominantly fish, they may occasionally form large congregations in rich coastal fishing areas. Divers overwinter along many European coasts, including the Black Sea, where they are most common in inshore waters along sheltered coasts (Ref. 12.29). Though globally common, black-throated divers are relatively scarce in the Eastern Black Sea, and are thus listed in both Russian Federation and Krasnodar Red Data Books.

**Figure 12.16 Occurrence of Protected Bird Species Observed in July 2013 surveys**

During the breeding season black-throated divers are threatened by the pollution of breeding waters, as well as disturbance. Wintering birds are vulnerable to coastal oil spills, especially in rich fishing grounds where large congregations may occur. The species is also commonly caught and drowned as by-catch in fishing nets (Ref. 12.3).
The Mediterranean gull breeds almost entirely in Europe, mainly on the Black Sea coast of Ukraine, with a recent spread to the northern Caucasian Plains (Ref. 12.3). Most populations of this species are fully migratory and travel along coastlines between their breeding and wintering areas, although some travel inland across Anatolia or follow major river valleys through Eastern and central Europe (Ref. 12.29). Outside the breeding season the species becomes entirely coastal, favouring estuaries, harbours, saline lagoons and other sheltered waters.

Mediterranean gulls migrate to breeding colonies at lagoons, estuaries and coastal saltmarshes from late-February to early-April, with most beginning to breed from early-May. A significant portion of the population also breeds on lakes and lowland marshes away from the coast (Ref. 12.29). It often breeds near but not among Sandwich terns *Sternula sandvicensis* (which also occurs in the Survey Area), or intermingling with black headed gulls (*Larus ridibundus*) (Ref. 12.3). The migration to the wintering grounds occurs from late-June onwards through to autumn. The gulls breed in colonies, usually of less than 1,000 pairs and occasionally in single pairs amidst colonies of other species.

Mediterranean gulls are susceptible to heavy losses as a result of tourist disturbance at breeding colonies. They may also be threatened by habitat loss resulting from coastal development and by marine pollution (e.g. oil spills and chemical discharges). Eggs and adults are collected from breeding colonies by fishermen in some areas of the species’ range (Ref. 12.3), though it is protected in Russia.

The Mediterranean or Yelkouan shearwater (*Puffinus yelkouan*) was formerly considered a subspecies of the Manx Shearwater (*P. puffinus*). It is a gregarious species, nesting in burrows which are only visited at night to avoid predation by large gulls. It breeds on islands and coastal cliffs in the eastern and central Mediterranean in spring and early summer, after which the birds disperse throughout their range.

Mediterranean shearwaters may range widely, with birds ringed in Malta having been observed in the Black Sea. Increasing numbers have been observed entering the Black Sea since the 1970s though there are no recent records of breeding birds there. Non-breeding birds are mostly present in the Black Sea from February to October, though some are present all year. This species has been reported to make large scale clockwise movements around the Black Sea, with flocks of up to 20,000 gathering in the north during summer months (Ref. 12.30).

The Mediterranean shearwater is under some threat from coastal development in its breeding range as well as predation of eggs and young by rats and cats. Adult birds are frequently caught in long line fisheries, and may also suffer from depleted food stocks due to the overfishing of anchovy in some areas (Ref. 12.6). Genetic studies suggest that the Mediterranean Shearwater may have suffered a marked population decline historically and thus could be vulnerable to adverse effects of inbreeding (Ref. 12.30). It was formerly classified as a species of least concern by the IUCN but in 2012 this was changed to vulnerable.

**12.4.6.3 Summary**

In November, 2010, the Caspian gull and the Mediterranean shearwater were the most abundant species observed offshore during transects. These birds were most likely observed wintering in and around the Survey Area. In April 2011, the great-crested grebe had the highest
abundance and was most likely migrating along the Black Sea coast. The cormorant was also abundant in this survey and was most likely migrating.

Coastal transects in both years recorded the highest abundances of birds, with no birds observed over 40 km from the coast in transects in April 2011.

Three species of conservation interest were encountered during in the Survey Area; the black-throated diver or Arctic loon, the Mediterranean gull and the Mediterranean shearwater. All three species were recorded in both the November 2010 and April 2011 surveys however, higher abundance of all three species were recorded in the April 2011 survey.

### 12.4.7 Marine mammals

#### 12.4.7.1 Background and Literature Review

Three species of cetacean reside in the Black Sea and these are listed in Table 12.21 along with their international, national and regional conservation status. The cetacean species off the Russian coast are represented by Black Sea subspecies, namely Black Sea harbour porpoise (*Phocoena phocoena relicta*), Black Sea bottlenose dolphin (*Tursiops truncatus ponticus*) and Black Sea common dolphin (*Delphinus delphis ponticus*). All three are protected at a national level by environmental legislation and governmental decrees (Ref. 12.3).

* IUCN: VU=Vulnerable; EN=Endangered. Red Data Books: 2= vulnerable species and subspecies declining in number; 3=rare species and subspecies.
** Species included in the *Agreement on Conservation of Biodiversity and Landscapes of the Convention on the Protection of the Black Sea from Pollution* (Ref. 12.31): E= endangered

Harbour porpoises inhabit mainly shallow waters (0 to 200 m deep) over the continental shelf around the entire perimeter of the Black Sea, although they also occur quite far offshore in deep water. Sizeable groups have been observed in the central Black Sea over 200 km from the nearest coast (Ref. 12.27). During warm periods they occur in the Azov Sea and Kerch Strait (among other areas). These different locations may represent geographically distinct breeding-calving-feeding areas.
Harbour porpoises in Russian waters undertake annual migrations, leaving the Azov Sea and north-western Black Sea before winter and returning in spring. The primary wintering areas are in the south-eastern Black Sea, extending into Georgian and Turkish waters. These are also the wintering grounds of anchovy, which, along with sprat, whiting and various goby species, are its principal prey. During their seasonal migration, animals may remain for a few days at different sites (usually bays with abundant fish, e.g. off the southern coast of Crimea) forming dense aggregations of some hundreds of individuals.

The ecology of Black Sea harbour porpoises may be considered unusual. It reflects the high degree of geographical isolation of their habitat, relatively low water salinity, significant seasonal fluctuations in water temperature, and large amount of anoxic waters saturated with H₂S usually below 150 to 200 m (Ref. 12.27).

Until 1983, unregulated hunting was the primary threat and the directed fishery for the porpoise drastically reduced populations. At present, incidental mortality in fishing nets is the most serious threat (Ref. 12.27). The majority (95%) of recorded cetacean entanglements in the Black Sea are of harbour porpoises, mostly in bottom set nets for turbot. Large-scale pelagic and small-scale coastal fisheries may affect Black Sea harbour porpoises indirectly by reducing their prey populations and degrading their habitat (Ref. 12.21). Other industrial activities, including shipping, dredging and hydrocarbon exploitation, also pose a threat (Ref. 12.32); for example an explosion at a gas-drilling platform in the Azov Sea in August 1982 resulted in the deaths of over 2,000 harbour porpoises (Ref. 12.27).

Commercial hunting of Black Sea cetaceans, including harbour porpoises, was banned in 1966 in the former USSR (the present Georgia, Russia and Ukraine), Bulgaria and Romania, and in 1983 Turkey and Russia assumed international obligations to protect Black Sea cetaceans as contracting parties to a wide range of international conventions 12. At a national level, the harbour porpoise is listed in the Red Data Book of the Russian Federation which means that the species should be monitored and managed by appropriate state or national programmes.

Common dolphins are distributed mainly offshore and visit shallow coastal waters following seasonal aggregations and regular mass migrations of their preferred prey, small pelagic fishes such as anchovy and sprat. Annual winter concentrations of anchovies in the south-eastern Black Sea and to a lesser degree, south of the Crimean peninsula, create favourable conditions for wintering concentrations of dolphins. Summer concentrations of sprats in the north-western, north-eastern and central Black Sea attract common dolphins to different feeding grounds in summer months. Common dolphins avoid waters with low salinity, and this may explain their absence from the Sea of Azov and scarcity in the Kerch Strait (Ref. 12.27).

Last century, the population collapsed because of directed takes. The total number of animals killed is unknown, but it was estimated that before the mid-1950s common dolphins comprised

94.8% of the total number of Black Sea cetaceans killed and processed in the former Soviet Union (Ref. 12.27).

Reduced prey availability has been considered an on-going major threat to Black Sea common dolphin since the late 1980s. Two mass mortality events that killed unknown but large numbers of common dolphins (in winter to spring 1990 and summer to autumn 1994) coincided with a drastic decline in the abundance of both principal prey species (anchovy and sprat), which has been attributed to overfishing, eutrophication and the invasion of the introduced predatory ctenophore *Mnemiopsis leidyi*, discussed in Section 12.4.1 (Ref. 12.27). This correlation between large die-offs of Black Sea common dolphins and prey scarcity could signify that reduced prey availability compromised the health of the dolphins and increased their susceptibility to viral infection. The 1994 summer-autumn die-off was also associated with an outbreak of morbillivirus (Ref. 12.27).

Bottlenose dolphins are distributed across the Black Sea shelf and may occur far offshore. In the northern Black Sea they form scattered communities of some tens to approximately 150 animals in different locations around the Crimean peninsula, including the Kerch Strait and coastal waters off the western and southern shores. Accumulations are also known to form off the Russian Caucasus and close to the Turkish coast. Bottlenose dolphins typically aggregate during autumn, winter and spring in a relatively small area between Cape Sarych and Cape Kbersone. According to a two-year photo-identification study in this area off the southern Crimea this “winter” accumulation consists of animals from other “summer” concentrations. Mean group sizes varied from 2.0 to 2.9 individuals in different surveyed areas (Ref. 12.27).

Bottlenose dolphins are primarily piscivorous (fish eating) in the Black Sea, taking both benthic and pelagic fishes, large and small. A total of 16 fish species have been reported as prey off the Crimean and Caucasian coasts including four species of mullet (*Liza aurata*, *L.saliens*, *Mugil cephalus* and *M. so-iuy*).

In the past, the population of bottlenose dolphins was subject to extensive commercial exploitation for the manufacture of oils, paint, glue, varnish, foodstuffs, medicine, soap, cosmetics, leather, “fish” meal and bone fertiliser. The total number of animals killed is unknown but it is acknowledged by the International Whaling Commission that all Black Sea cetacean populations, including bottlenose dolphins, were greatly reduced by the dolphin fishery. Isolated cases of deliberate killing and harassment (with pyrotechnic devices and firearms) have been reported in coastal fisheries. For instance, at least two bottlenose dolphins were reportedly shot in Balaklava, Ukraine in 2004 (Ref. 12.27).

Since the mid-1960s, hundreds of bottlenose dolphins (probably over 1,000) have been live-captured in Russia, Ukraine and Romania for military, commercial and scientific purposes. The capture operations sometimes caused accidental (but usually unreported) deaths. In recent years, 10 to 20 animals have been taken annually from May to June from a small area in the Kerch Strait (Ref. 12.27). During the 1980s to early 2000s, the number of facilities for dolphin shows and “swim with dolphins” programmes greatly increased in Black Sea countries. The export of bottlenose dolphins from Russia and Ukraine for permanent and seasonal shows also expanded to over 20 countries in Europe and the Middle East. According to CITES statistics, at least 92 individuals were removed from the Black Sea region during 1990 to 1999 and Russia reportedly has exported at least 66 for traveling shows since 1997 (Ref. 12.27).
At present, incidental mortality in fishing gear is probably one of the main threats to Black Sea bottlenose dolphin. They are known to be susceptible to capture in a variety of fishing nets, including bottom-set gillnets for turbot, spiny dogfish, sturgeon and sole, purse seines for mullet and anchovy, trammel nets and trap nets. However, only bottom-set gillnets are thought to take significant numbers, especially during the turbot fishing season between April and June. Small-scale coastal fisheries also affect Black Sea bottlenose dolphins indirectly by depleting their prey populations (Ref. 12.21). Though there has been concern regarding decreasing populations of indigenous mullets (*M. cephalus* and *Lisa* spp.) this might be offset to some extent by the introduced far-east mullet, *M. so-iyor*, which has since become abundant in the northern Black Sea and may be a factor a recent marked increase in dolphin density along the Crimean coast (Ref. 12.27).

Microbial pollution from untreated sewage in coastal waters poses a chronic risk of opportunistic bacterial infections to bottlenose dolphins, and there is evidence that they (as well as other Black Sea cetaceans) are exposed to morbillivirus infection (Ref. 12.27). Another potential source of exotic infections and genetic “pollution” is the poorly managed intentional releases and spontaneous escapes of captive bottlenose dolphins and other marine mammals from dolphinaria.

### 12.4.7.2 Survey

**Survey Area**

The survey locations given in Figure 12.17 make up the Survey Area discussed in this section for marine mammals. Information on the water depth, distance from shore and survey methodologies is given in Table 12.1 and Table 12.3.

Marine mammals transects were conducted along with the seabird surveys in November 2010, April to June 2011 and July 2013. Figure 12.17 and Figure 12.18 show the locations of these surveys. The surveys were conducted at the following locations:

- Ten transects in November 2010;
- Nine transects in November 2010 (during fish trawls);
- Twelve transects, including some in offshore areas, in June 2011; and
- In July 2013, 38 transects and 51 stations in coastal region were sampled.

Coastal surveys were also conducted in June 2010 in the vicinity of Anapa and along the Russian coast.

Survey Results

In surveys conducted along the Russian Black Sea coast in June 2010, the bottlenose dolphin and common dolphin were observed. The locations for these sightings are shown in Figure 12.19.

Figure 12.19 Cetaceans Observed in 2010 Surveys

In transects conducted in November 2010, the bottlenose dolphin and common dolphin were observed. The most abundant species was the common dolphin. The bottlenose dolphin was only observed during fish surveys, not during transects (Table 12.22).

Note: there is a level of uncertainty regarding the sightings during this survey. It is unclear if repeat sightings of cetacean species have been accounted for or not, thus these numbers are taken as indicative.

In April 2011 surveys (see locations in Figure 12.17 and Figure 12.18), 89 cetaceans were observed from 19 transects; 9 harbour porpoise, 24 bottlenose dolphin and 56 common dolphin. Harbour porpoises were mainly observed in water depths of less than 50 m and not more than 20 km from the shore (mostly within 5 km of the shore). Four individuals and four groups of two to six harbour porpoises were recorded. Common dolphins observed during the April 2011 survey were widely dispersed in the Survey Area. The majority of individuals (95%) were observed around 40 km from the coast. Seven single individuals and 10 groups from two to 12 dolphins were recorded. Like the harbour porpoise, bottlenose dolphins were more commonly observed in shallower waters (within 15 km of the coast) but were also observed offshore. The spatial distribution of cetacean species is comparable to the data from the IUCN report (Ref. 12.27) which mentions harbour porpoise as more commonly observed in 0-200 m water depth and common dolphins observed further offshore. In total, 26 individuals were recorded, consisting of two individuals and eight groups from two to six (Ref. 12.1).

In July 2013 a total of 269 cetaceans were recorded, 96 individuals observed from 38 transects and 173 from 51 fixed stations. The higher total number of sightings reflects a more intensive survey carried out in coastal waters (all stations and transects were within 8 km of the shore). The common dolphin was the dominant species with 208 observations recorded and there were 42 bottlenose dolphin and 19 porpoise seen in the same period (Table 12.23) (Figure 12.20).

The harbour porpoise was observed in low numbers across the survey area with an average abundance of 2 animals per 10 km transect (Figure 12.20). This species is not particularly gregarious with most animals seen singly or in pairs and no groups of more than four individuals observed.

The common dolphin is the most abundant and widespread cetacean observed in the Survey Area (Figure 12.20). During transect surveys the sightings of common dolphin was an average of 5.4 individuals per 10 km. Mostly adults of the species were observed during the surveys with only two young noted during the entire survey. The common dolphin was present mostly in
small groups of 3 to 6 individuals but occasional larger groups of 10 to 12 were seen, as were solitary animals.

The bottlenose dolphin was also observed, but in fairly low numbers compared to common dolphin, with an average of 2 animals per 10 km of transect (Figure 12.20). They were generally present in small groupings although a group of 12 individuals, including two young, was noted, together with a group of common dolphin, next to a fishing boat.

Chapter 12 Marine Ecology

12.4.7.3 Summary

There are three cetacean species known to inhabit the Black Sea; the harbour porpoise, bottlenose dolphin and the common dolphin. Harbour porpoise are more commonly observed in coastal areas within 200 m water depth. Common and bottlenose dolphin were observed further offshore than the harbour porpoise.

In coastal surveys in June 2010 and July 2013, all three species (harbour porpoise, bottlenose dolphin and common dolphin) were observed. The common dolphin was the species most likely to be observed; during all surveys in the Survey Area it was more widespread and considerably more abundant than the bottlenose dolphin and porpoise. In the offshore surveys in November 2010, common dolphins were most abundant and bottlenose dolphins were also observed. In April 2011, all three species were also observed. There were more sightings of the common dolphin, indicating it is the most abundant cetacean in the Survey Area. This species was also the most widely distributed cetacean species in the Survey Area. The majority of cetaceans were observed around 40 km from the coast and harbour porpoise and bottlenose dolphins were more commonly found in shallow waters (around 15 km from the coast).

It has not been possible to determine seasonal patterns in the distribution of these species in the Survey Area or known breeding areas or periods due to lack of data.
12.4.8 Protected Areas and Species

Although the pipeline route does not pass directly through any marine protected areas or nature reserves, it does pass within approximately 2 km of the marine part of the Utrish SPNA, and through the Anapa Bank fishery protected zone (Figure 12.21).

There is also the onshore Anapa sanitary protection area located approximately 500 m to the northeast and southwest of the onshore Project Area. Within this sanitary protection area, only works which do not adversely impact the natural resources and the sanitary conditions of the resort area of Anapa are permitted.

12.4.8.1 Protected Areas

Anapa Bank

The designated area known as the ‘Anapskya Bank’ or ‘Anapa Bank’ extends over approximately 730 km² and is located in the Kerch-Taman region (Figure 12.21). This area is designated as an important fishing ground. Fishing is seasonally restricted to allow the replenishment of fish stocks and trawl fishing and fishing with stationary nets with a cell size of more than 50 mm is forbidden. Since 2011, a section of this area has been made available for sprat and anchovy trawling under the Russian Fishery Regulations (Ref. 12.1).

The Anapa Bank fishery protected zone was initially set up to become a breeding ground for the commercially important Black Sea turbot. The Black Sea turbot can reach 85 cm and 15 kg and attain sexual maturity at the age of seven to ten years. In the summer, they keep close to the shore, where they spawn and feed. Their diet consists of whiting, sprat, gobies, Black Sea goatfish and crustaceans. Annual spawning occurs from May to July. The roe is pelagic and fertility ranges from 3 to 13 million eggs. Black Sea turbot do not undertake long migrations along the coast and only swim locally to feed and reproduce. The North Caucasus and Anapa schools swim in the north-eastern part of the Black Sea (Ref. 12.1).

Fishing for sprat is permitted between the beginning of July and the end of September at water depths of more than 40 m. Commercially exploitable populations are found from April until September and since 2011, fishing in deeper waters (over 40 m depth) has been allowed.

Anchovy fishing is allowed from the beginning of October until the 15 March annually at water depths of more than 20 m. Anchovy fattens and spawns in the Sea of Azov in the summer months and migrates to the Russian and Georgian shores of the Black Sea as waters cool until the following spring. Thus, in the Black Sea territorial waters of Russia, anchovy form commercial concentrations during the cold season from October to April.

---

13 The Anapskaya Bank was initially designated in 1986 by Decree of the Ministry of Fisheries of the USSR. The area where fishing was prohibited was reduced by the Resolution of the Scientific Fishery Council of the Azov and Black Sea Basin in 1999. In 2011 the fishing ban was further reduced and it now merely consists of seasonal restrictions to enable the replenishment of fish stock.

Utrish

In 1988, the Bolshoi Utrish reserve was included in the Register of State Reserves located on the territory of the Krasnodar Region\(^{14}\). The total area of the reserve is 5,112 hectares, of which 2,530 hectares is offshore (to a water depth of 40 m) (Figure 12.21). The marine sector of the reserve provides protection for a number of flora and fauna species listed in the Red Books of the Krasnodar Krai and the Russian Federation (algal species are listed in Table 12.24). The Pipeline route does not cross the offshore part of the marine reserve (Figure 12.21) but it is likely that it will host some of the protected species found in the nearby reserve. From surveys conducted on the Abrau Peninsula, some 20 km further east along the coast than the Utrish reserve, the main benthic communities present in the area have been identified. Utrish at its closest point is around 2 km from the Project Area.

The vegetated zone can be divided into three groups broadly based on water depth. In very shallow waters (up to about 2 m water depth) a low biomass mosaic algal community made up of ephemeral greens such as *Enteromorpha* together with *Ceramium ciliation*, *Cladophera* sp. *Lophosiphonia obscure*, *Padina pavonia* and *Dilophus fasciola* is found. This shallow water association is almost uniform for the whole coast (Ref. 12.4).

The mid zone, at depths from 2 to 10 m, is dominated by *Cystoseira* communities, which includes two species; *Cystoseira barbata* and *C. crinita*. Nearly all sampled stations at depths of 2 m, 5 m and 10 m show this association which is characterised by multi-layering of algae and high species richness. The highest algal biomass is observed at depths of 2 to 5 m (up to 35%). Although in some areas algal biomass it is quite high even at 10 m, it usually it drops to less than 1% at the bottom phytal zone. This is primarily due to increasing light limitation at depths of over 10 m, especially in the recent years when dense plankton blooms may attenuate light. The *Cystoseira* communities form the basis of much of the benthos of the north Caucasus region.

The final algal community, found in water depths over 10 m, is dominated by perennial red algae such as *Phyllophora nervosa*, although more recently a second species, the green algae *Codium vermilara* was also found to be equally dominant within the association. This significant change in the bottom phytal zone is a result of the restructuring of the entire ecosystem of the Black Sea due to pollution and other anthropogenic impacts, which has been observed in the latter half of the 20th century (Ref. 12.4).

Preliminary information regarding the composition of the protected species of seaweed in the Utrish reserve is listed in Table 12.24 including information on the conservation status of these species in Russia. There is potential that these species will also be recorded in the waters of the Survey Area although only three species were observed in 2011 surveys (Ref. 12.1).

The dominant *Cystoseira* associations support a diverse invertebrate fauna with high numbers of amphipod, polychaete and gastropod species. However, biomass is dominated by the mussel

\(^{14}\) Annex No 2 to the Decision of the Executive Committee of the Krasnodar Regional Council of People's Deputies No 326 of 14.07.1988
**Mytilaster lineatus** which makes up 70 to 95% of the total community biomass. Mytilaster covers the *Cystoseira* thalli in a solid layer, and the older the thallus, the greater the biomass of the molluscs covering it. Thus, *Mytilaster* biomass is often a function of the mean age of the algae which results in an uneven distribution of the mussel.

On soft sediments, macroalgae are absent and fauna dominate with different associations depending on water depth and sediment conditions. On silted sands at a depth of 20 to 25 m a community dominated by the bivalve mollusc *Chamelea gallina* was observed. Other bivalves, particularly *Spisula subtruncata*, together with gastropods and crustaceans were also present in this association (Ref. 12.4).

In silted muddy habitats at depths of 25 to 35 m a more diverse community, dominated by the bivalves *Cunearca cornea* and *Pitar rudis* was observed (Ref. 12.4). These two bivalves made up 61 to 87% of the faunal biomass. Species diversity in the association was dominated by bivalve molluscs and polychaetes together with a small number of gastropods, crustaceans and other taxa.

In water depths of 35 to 50 m, a regional *Mytilus galloprovincialis* community was observed. This comparatively diverse community of 40 species was dominated taxonomically by polychaetes, bivalves and crustaceans with a small number of gastropods, ascidians and other taxa. However, biomass was dominated by bivalves, particularly the dominant bivalve *Mytilus galloprovincialis* which accounted for between 59 and 80% of the total biomass per station sampled (Ref. 12.4).

At depths greater than 50 m a *Modiolula phaseolina* (reported as *Modiolus phaseolinus*) community was observed. The three most common species in this community are the bivalve *M. phaseolina*, the polychaete worm *Terebellides stroemi* and the brittlestar *Amphiura stepanov* that collectively comprise 80 to 99% of the biomass on the stations sampled.

Thus, the distribution of benthic associations in the Utrish area was summarised as follows:

- 1 to 10 m – algal community dominated by *Cystoseira barbata* + *Cystoseira crinita*;
- 10 to 20 m – algal community of *Phyllophora nervosa* + *Codium vermilaera*;
- 20 to 35 m – rocky ground – no flora or fauna;
- 20 to 35 m – soft sediments with a mosaic of primarily infaunal animals, particularly bivalves *Chamelea gallina*, *Anadara inaequivalvis* and *Pitar rudis*;
- 35 to 50 m – an association of fauna dominated by the mussel *Mytilus galloprovincialis*; and
- 50 to 75 m – an association of fauna dominated by the bivalve *Modiolus phaseolinus*.

There were no macro-invertebrates recorded from the Utrish reserve of the Black Sea Coast included in the Russian Red Data Book, but two species of crab are listed in Annex 3 of the Red Data Book of the Krasnodar Krai Region. These are the stone crab (*Eriphia verrucosa*) which inhabits coastal waters and the spider crab (*Macropodia rostrata*) which is found in waters to 50 m.

* Red Data Books: 2 = vulnerable species and subspecies declining in number; 3 = rare species and subspecies; 5 = rehabilitated and recovering
** Species observed in 2011 surveys (see Ref. 12.1)

The taxonomic constitution of the fish fauna in the marine part of Utrish is quite diverse and contains 71 species of fish, belonging to 35 families and 15 orders. This makes up nearly 37% of the fish fauna in the whole Black Sea and around 70% of fish species found in the Russian part of the Black Sea. The core of the community consists of Mediterranean migrants, the warm water species. The anadromous and semi-anadromous species that occur here consist of the sturgeon and herring families (Acipenseridae and Clupeidae), while brackish water species exist in the Clupeidae and Gobiidae families. Six species of fish listed in the Red Books of the Krasnodar Krai and Russian Federation are present in the Utrish reserve and so may also be present in the Survey Area (Table 12.25).

In terms of seabirds, Utrish is significant for the conservation of the black-throated diver which is regularly recorded as a migrating and wintering species of the western Black Sea area. The species’ successful wintering is determined by the rich food reserve of the Utrish region. A further three species of bird listed in the Red Books have been observed in the Utrish reserve (Ref. 12.1) and may be present in the Survey Area; the black-throated diver, great black-headed gull and the black-headed gull.
### 12.4.8.2 Protected Species

A number of species of conservation concern, listed in the Red Data Books of the Russian Federation and the Krasnodar Krai or included in the IUCN Red List, have been directly observed in the Survey Area (Table 12.25) (Ref. 12.1). Some of these have also been designated as species of concern by the Black Sea Convention. These are:

- Two species of macroalgae;
- Two species of fish;
- Three species of seabirds; and
- Three species of mammals.

A number of other protected fish species and one seabird, whilst not observed directly in the survey area, have been reported from nearby areas. It is possible, therefore, that these species may be present in the survey area and have for this reason been identified in Table 12.26 (Ref. 12.1).

12.4.9 **Critical Habitat**

12.4.9.1 **Overview**

The Project Area lies within some Tier 2 critical habitat as defined by the IFC\(^{15}\). It should be noted that the Project Area does not, per se, represent particular habitat that is not replicated...
elsewhere in the Russian Black Sea; it is merely part of a wider zone that meets the requisite criteria. Further details of the rationale for the determination of critical habitat are provided in IFC Guidance Note 6\(^{16}\). Full details of the determination of marine critical habitat in the Project Area are provided in Appendix 12.1: Marine Critical Habitat Determination.

The critical habitat assessment has based on the establishment of ‘discrete management units’ (DMUs). Paragraph 65 of Guidance Note 6 defines a DMU as “an area with a clearly demarcated boundary within which the biological communities and/or management issues have more in common with each other than they do with those in adjacent areas”. For the purposes of this assessment, the Project has defined three DMUs:

- Coastal Zone: water depths of less than 30 m along the Russian coastal margin of the Black Sea;
- Shelf Zone: between 30 m and 200 m water depth, characterised by muddy substrates with a variety of bivalve, polychaete and burrowing anemone dominated communities; and
- Open Sea: from 200 m water depth to the edge of the Russian EEZ.

### 12.4.9.2 Critical Habitat for Endangered Species

Beluga, Russian, and stellate sturgeon have been observed on single occasions during surveys in the Study Area. It is unlikely that globally significant populations regularly occur here, though single individuals probably do, thus the coastal zone qualifies as Tier 2 critical habitat for these species based on criterion 1 (supports the regular occurrence of a single individual of a critically endangered species) as defined by the IFC (Ref. 12.33).

Black Sea bottlenose dolphins and harbour porpoises have been regularly observed in the Project Area and it is likely that both the coastal zone and open sea are Tier 2 critical habitat for these species, based on criterion 1 which is defined as “Habitat of significant importance to CR or EN species that are wide-ranging and/or whose population distribution is not well understood and where the loss of such a habitat could potentially impact the long-term survivability of the species” and “habitat containing nationally / regionally important concentrations of an EN, CR or equivalent national / regional listing”. The Tier 2 critical habitat classification may also be based on Criterion 2 which is defined as “Habitat known to sustain ≥ 1 percent but < 95 percent of the global population of an endemic or restricted-range species where that habitat could be considered a discrete management unit for that species, where data are available and/or based on expert judgment”.

### 12.4.9.3 Critical Habitat for Migratory and Congregatory Species

Though definitive data are not available, it is reasonable to suppose that both the coastal zone and open sea areas qualify as Tier 2 critical habitat for Black Sea turbot based on criterion 3 which is defined as “Habitat known to sustain, on a cyclical or otherwise regular basis, ≥ 1

---

\(^{16}\) IFC Guidance Notes are not Project standards for the South Stream Offshore Pipeline Project. They are described in Equator Principles III as follows: ‘Guidance Notes accompany each Performance Standard. Equator Principles Financial Institutions (EPIIs) do not formally adopt the Guidance Notes however EPIIs and clients may find them useful points of reference when seeking further guidance on or interpreting the Performance Standards.’
percent but < 95 percent of the global population of a migratory or congregatory species at any point of the species’ lifecycle and where that habitat could be considered a discrete management unit for that species, where adequate data are available and/or based on expert judgment.”

If the Project Area is considered, data suggest that it does not meet the 1% global or biogeographic population criteria, and although small dense flocks of birds are occasionally observed, they are unlikely to exceed the 20,000 bird threshold specified in IBA’s criterion A4. However, the very large scale of the DMUs in this case means that it is reasonable to suppose that the 20,000 bird threshold might be exceeded for the entire coastal area and thus there is the potential for it to qualify as Critical Habitat. It should nonetheless be stressed that this is an artefact of the size of the DMU, rather than a real reflection of the conservation importance of the area to birds per se.

The coastal zone may also qualify as Tier 2 Critical habitat under IBA Criterion A4 (see Appendix 12.1 for further details), in that it supports over 20,000 birds. It should be noted however, that this is largely an artefact of the size of the DMU rather than its conservation importance to birds.

12.5 Impact Assessment

12.5.1 Impact Assessment Methodology

The overall assessment methodology is detailed in Chapter 3 Impact Assessment Methodology, whereby receptor sensitivity and impact magnitude are used to determine the overall significance of an impact. Specific criteria relating to the sensitivity of marine species and marine habitats, and to the magnitude of marine impacts, are discussed in Section 12.5.1.1.

Impacts are presented below based on discussion according to receptor type, to give a complete picture of the effects of the Project on a given habitat or species group. However, because mitigation is mainly applied at source rather than receptor, it is more appropriate to list mitigation measures according to project activity. This allows a clearer perspective of how an activity can be managed as a whole to minimise, mitigate or manage marine ecological impacts.

This chapter demonstrates Project adherence to the ‘mitigation hierarchy’ as defined in IFC PS(6), i.e. impacts should be progressively avoided, minimised, and restored, with priority given to the actions which are earliest in the hierarchy. Therefore, the Project has sought and will continue to seek to avoid impacts on biodiversity. When avoidance of impacts is not possible, measures to reduce impacts to an acceptable level and to restore biodiversity, will be implemented. Given the complexity in predicting project impacts on biodiversity over the long term, the Project will adopt a practice of adaptive management in which the implementation of mitigation and management measures are responsive to changing conditions and the results of monitoring until the necessary biodiversity requirements of no net loss / biodiversity gain and fulfilment of management objectives have been achieved.

The project’s mitigation strategy will be described in a Biodiversity Action Plan (BAP) and will be designed to achieve net gains of those biodiversity values for which the critical habitat was
designated. Development of the BAP will take into consideration relevant industry guidance, and will allow for adaptive management and consultation with stakeholders on topics of conservation related to the Project’s biodiversity interests”

The Project involves a wide range of activities that have the potential to impact the marine environment, primarily during the Construction Phase. The relevant activities are summarised in Table 12.27. Decommissioning activities are not known at this time. GIIP is usually to leave marine pipelines in situ, which would have impacts indistinguishable from those set out for the Operational Phase. However, for the purposes of this ESIA Report, wholesale pipe removal is also considered.

12.5.1.1 Impact Assessment Criteria

Receptor Sensitivity

The receptor sensitivity criteria for marine ecological receptors have been harmonised, where appropriate, with those adopted for terrestrial ecological receptors (Chapter 11 Terrestrial Ecology), in order to allow for a consistent and integrated approach in assessing the Project’s impact on ecology and biodiversity. However, though the approaches are harmonised they are
not identical. Where the terrestrial ecological assessment focuses on conservation and protection criteria, the marine assessment includes consideration of ecological function. This is because there are marine species and communities that are important to the ecosystem that are neither rare nor protected by any designation (e.g. bivalves providing bio-filtration, or macroalgae providing habitat for other notable or commercially valuable species). This approach therefore includes consideration of flora, fauna, ecological processes and nature conservation.

It should be noted that for the purposes of this ESIA, the concept of “sensitivity” is more closely related to receptor value (importance) than receptor vulnerability (resistance to change), though elements of both are considered in the criteria. Vulnerability considerations are also incorporated into the criteria for impact magnitude set out below.

The marine environment encompasses a wide variety of ecological receptors as detailed in the baseline section above. At the highest level, these can be divided into habitats and species, for which it is appropriate to derive separate assessment criteria. The main habitat types that occur in the Project Area are:

- Soft substrate benthic habitats;
- Seaweed stands; and
- Deep sea microbial communities.

Potential critical habitat has been identified in the baseline Section 12.4.9, encompassing wide areas of the sea (Appendix 12.1). Because the Project does not have the scope or scale to impact such extended areas, the assessment of impacts relating to critical habitats has focussed on the species for which that habitat is considered critical rather than the habitat itself.

Species are broadly classified into the following groups (though consideration is given to individual named species where they are of particular conservation concern or known to be particularly vulnerable to specific impact):

- Plankton;
- Benthic fauna;
- Fish;
- Seabirds; and
- Marine mammals.

Sensitivity criteria have been developed separately for habitats and species, as set out below in Table 12.28 and Table 12.29 respectively. Where possible both international and national criteria and standards have been applied. It should further be noted that on occasion a receptor is assigned a sensitivity range. This is to allow the adoption of a precautionary approach to highlight specific potential vulnerabilities within a wider context (e.g. the presence of species of conservation interest in an assemblage that is otherwise less sensitive) but where the impacts can be managed by the same set of Project design controls and mitigation measures.
**Table 12.28 Receptor Sensitivity Criteria for Marine Habitats**

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
<th>Applicable Legal Standards</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>A site, habitat or assemblage of species which has designated conservation status at an international and national scale; or Areas of particular biodiversity importance, that my support populations of restricted range, endemic or endangered species, or is in itself unique or threatened*; or Areas that support large populations (in a national or international context) of migratory species**; or Habitats that provide key ecosystem functions.</td>
<td>International: Designated areas or habitat under IUCN category Ia to IV (Habitat / Species Management Area and above). Russia: Designated habitat in Russian law on “On Specially Protected Natural Areas” No. 33-FZ.</td>
</tr>
<tr>
<td>Moderate</td>
<td>A site, habitat or assemblage of species which has designated conservation status at a National scale; or ‘Natural Habitat’ IFC classification: Areas composed of viable assemblages of plant and/or animal species of largely native origin, and/or where human activity has not essentially modified an area's primary ecological functions and species composition.</td>
<td>Designated habitat in Russian law on “On Specially Protected Natural Areas” No. 33-FZ.</td>
</tr>
<tr>
<td>Low</td>
<td>Habitats occurring outside of any designation; or ‘Modified Habitat’ IFC classification: Areas that may contain a large proportion of plant and/or animal species of non-native origin, and/or where human activity has substantially modified an area's primary ecological functions and species composition. Modified habitats may include areas managed for agriculture, forest plantations, reclaimed coastal zones, and reclaimed wetlands.</td>
<td>None applicable</td>
</tr>
<tr>
<td>Negligible</td>
<td>Habitats that are either appreciably degraded or disturbed by human activity or have high proportions of invasive / non-native species; or Do not support any key ecosystem functions.</td>
<td>None applicable</td>
</tr>
</tbody>
</table>

* As listed on the International Union for the Conservation of Nature (IUCN) Red List of Threatened Species

** There criteria are similar to those used by the IFC to determine “Critical Habitat”. It should be stressed however, that designation of critical habitat is not in itself a criterion, rather the result of applying conservation criteria. Either modified or natural habitats may be considered critical if they support the appropriate species or processes. A marine critical habitats appraisal has been carried out in parallel to this ESIA and presented in Appendix 12.1.

**Habitats**

Soft substrate benthic habitats include sandy and silty seabed at a variety of depths. This habitat type supports a diversity of benthic communities and infaunal species. The precise composition of the flora and fauna depends on several physico-chemical variables such as water depth, sediment particle size and organic content. This mosaic of different communities includes areas dominated by the mussel *Modiolula phaseolina* and other bivalves. The significance of this is that such communities provide an important ecological service due their bio-filtration capacity when present in high abundance. The mobile nature of soft seabed means that soft substrate benthic communities are often able to withstand physical perturbation and to re-establish
disturbed areas relatively quickly. Despite their abundance and wide distribution, the important ecological roles these communities serve (as, inter alia, structural species, prey and bio-filters), means they are considered generally only moderately sensitive.

Seaweed-dominated communities exist on hard substrates. Most notable of these are algae of the genera Phyllophora and Cystoseira. *P. brodiaei* and *P. nervosa* are listed as vulnerable in the Black Sea Red Data Book while *Cystoseira barbata* and *C. crinata* are both listed as endangered in the Black Sea Red Data Book. *P. crispa* (=*P. nervosa*) is listed as vulnerable in the RDBKK. Macroalgal stands are known to exist in the Project Area and a dense *Cystoseira* community is present at a water depth of approximately 10 m, becoming sparser at depths between 10 m and 20 m. *P. crispa* was also recorded in the Survey Area (though not in discrete stands) and is thought to be present in the Utrish nature reserve which is located, at its closest point, around 2 km from the Project Area. These habitats are considered highly sensitive.

Very little is known about the offshore deep water seabed of the Black Sea abyssal plain. Anoxic conditions and the presence of H$_2$S mean that only sulphur metabolising bacteria and one infaunal species of microscopic metazoan have been observed to survive in these zones. It is thought that such communities are widespread in the deep sea, but the specific diversity and abundance of organisms in this habitat is not known. In some circumstances deep sea bacterial communities can form reef structures or microbial mats, though such communities were not observed along the Pipeline alignment (Ref. 12.15; Appendix 7.1) and in the Black Sea they are thought to be confined to the northwest shelf. On the basis of available survey data, deep sea microbial communities are considered to be low sensitivity.

Species

Plankton are not particularly sensitive to the impact of pipe-laying activities. Their dispersed nature, very high numbers and relatively short generation time means the populations themselves are resilient, even though some sensitive and rare species, e.g. sturgeons, have planktonic larvae. Project Activities alone have relatively little scope to impact the water column, and thus plankton are generally considered of moderate to low sensitivity. The reason the sensitivity is not assessed purely as low is due to the possible presence of the larvae of endangered species in the ichthyoplankton.

Although some benthic invertebrates are mobile, their generally small size gives them a restricted ability to avoid large scale impacts. Because of this, and the fact that they can be important in overall ecosystem functions and services (e.g. biofiltration, food for fish), benthic invertebrates are considered of moderate sensitivity.

Several protected fish species have been recorded in the Project’s ecological surveys, most notably two species of sturgeon that are critically endangered (Russian sturgeon, *Acipenser gueldenstaedtii* and Stellate sturgeon, *A.stellatus*). Two other protected species; the thornback ray (*Raja clavata* listed under IUCN as Near Threatened), and leaping mullet (*Lisa saliens* listed in the RDBKK), were recorded in the Survey Area. Records from Utrish also suggest the presence (albeit occasional) of the critically endangered beluga sturgeon (*Huso huso*). Despite the ability of many fish to avoid some areas of impact, the presence of endangered species means the fish community is considered to be of moderate to high sensitivity.
A wide variety of shore and seabirds inhabit the Russian nearshore at different times of year. Birds are most vulnerable to disturbance when nesting or moulting and their ability to avoid sources of impact is reduced. Three locally endangered species are present in the Project Area; the black-throated diver *Gavia arctica*, the Mediterranean gull *Larus melanocephalus* and the Mediterranean shearwater *Puffinus yelkouan*. The latter is also globally vulnerable. Despite the limited scope for the Project to interact with seabirds, the presence of endangered species in the Survey Area for at least part of the year means their sensitivity as receptors is considered moderate to high.

Whilst highly mobile and generally able to avoid areas of adverse impact, the sensory acuity of marine mammals means they have the potential to be impacted by high levels of unnatural sound in the ocean. Two of the three cetacean species that occur off the Russian coast, namely harbour porpoise (*Phocaena phocaena relicta*) and bottlenose dolphin (*Tursiops truncatus ponticus*) are globally endangered and included in the RBDs of the Russian Federation and Krasnodar Krai. The third species, the common dolphin (*Delphinus delphis ponticus*), is globally vulnerable and listed in the Black Sea (Bucharest) Convention Annex III, but is not in the Russian RDB. Because of their protected status, marine mammals are considered highly sensitive receptors.

A summary of the receptors considered within this chapter and their associated sensitivity ranking is provided in Table 12.30 below.

Impact Magnitude

Consistent with the approach outlined above, common impact magnitude criteria have been developed for marine and terrestrial ecological receptors as shown in Table 12.31 and Table 12.32. As the magnitude of potential impacts upon habitats and species is highly variable and difficult to quantify these definitions have been developed, in line with Chapter 3 Impact Assessment Methodology, to provide case specific flexibility based on professional judgement and experience in GIIP. These criteria, as previously mentioned, include consideration of the degree of change as well as the ability of receptors to withstand that change. Furthermore, in assigning magnitude, environmental controls built into the design of the project are considered.

Table 12.31 Marine Habitat - Impact Magnitude

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>The project may adversely affect the integrity of an area or region, by substantially changing in the long term its ecological features, structures and functions, across its whole area, that enable it to sustain the habitat, complex of habitats and/or population levels of species that makes it important.</td>
</tr>
<tr>
<td>Moderate</td>
<td>The area’s integrity will not be adversely affected in the long term, but the Project is likely to affect some, if not all, of the area’s ecological features, structures and functions in the short or medium term. The area or region may be able to recover through natural regeneration and restoration.</td>
</tr>
<tr>
<td>Low</td>
<td>Neither of the above applies, but some minor impacts of limited extent, or to some elements of the area, are evident but easy to recover through natural regeneration.</td>
</tr>
<tr>
<td>Negligible</td>
<td>Indiscernible from natural variability.</td>

### Determining Impact Significance

As outlined in **Chapter 3 Impact Assessment Methodology** of this document, the significance of an impact on an identified and valued receptor is determined as a relationship between the sensitivity of the receptor and the magnitude of the predicted impact. The relationship between receptor sensitivity and impact magnitude, and the resultant significance of an impact (positive or negative), is presented in Table 12.33 and definitions of the impact significance ratings are given in Table 12.34.

</thead>
<tbody>
<tr>
<td></td>
<td>Significant. Impacts with a “high” significance are likely to disrupt the function and value of the resource / receptor, and may have broader systemic consequences (e.g. ecosystem or social well-being). These impacts are a priority for mitigation in order to avoid or reduce the significance of the impact.</td>
<td>Significant. Impacts with a “moderate” significance are likely to be noticeable and result in lasting changes to baseline conditions, which may cause hardship to or degradation of the resource / receptor, although the overall function and value of the resource / receptor is not disrupted. These impacts are a priority for mitigation in order to avoid or reduce the significance of the impact.</td>
<td>Detectable but not significant. Impacts with a &quot;low&quot; significance are expected to be noticeable changes to baseline conditions, beyond natural variation, but are not expected to cause hardship, degradation, or impair the function and value of the resource / receptor. However, these impacts warrant the attention of decision-makers, and should be avoided or mitigated where practicable.</td>
<td>Not Significant. Any impacts are expected to be indistinguishable from the baseline or within the natural level of variation. These impacts do not require mitigation and are not a concern of the decision-making process.</td>
</tr>
</tbody>
</table>

#### 12.5.1.2 Modelling Undertaken

While no specific ecological modelling has been undertaken, this section draws on the results of sediment dispersion modelling with respect to benthic impacts, and on the results of acoustic modelling with respect to the impacts of underwater noise on fish and cetaceans. Details of the sediment dispersion and underwater noise modelling are provided in Appendix 12.2: Sediment Dispersion Study and Appendix 12.3: Underwater Noise Study respectively.

#### 12.5.2 Assessment of Impacts: Construction and Pre-Commissioning

##### 12.5.2.1 Introduction

Compared to other Project phases, construction and pre-commissioning activities have the greatest scope to impact the marine environment, and all the receptors discussed above may be impacted at some stage. However, the Project has been designed to reduce a number of impacts at source. Design controls have been categorised by potential impact from a given Project activity. These design controls attempted to firstly either avoid or minimise the risk of an impact considering the IFC mitigation hierarchy as discussed in Chapter 3 Impact Assessment Methodology. Potential construction and pre-commissioning impacts are assessed on this basis. Additional mitigation and monitoring measures are then identified that can further reduce impacts to as low as possible, and the residual impact is assessed. The
design controls included in Table 12.35 relate to Construction and Pre-Commissioning, Commissioning and Operational and Decommissioning Phases and have been included in the pre-mitigation impact assessment in Section 12.5.2.2, 12.5.3.2 and 12.5.4.2.

<td>A Seabed Intervention Construction Management Plan (CMP) will be prepared including measures for minimising turbidity, managing overspill etc.</td>
</tr>
<tr>
<td>Open trench dredging will be minimised.</td>
</tr>
<tr>
<td>Microtunnelling will be performed at the shore approach / landfall instead of open cut trenching.</td>
</tr>
<tr>
<td>Rock placement will be kept at the practical minimum to ensure pipeline stability and safety and in accordance with detailed design.</td>
</tr>
<tr>
<td>The appointed pipeline installation contractor will be required to develop anchor patterns and procedures and undertake a risk assessment to minimise impact to areas of concern.</td>
</tr>
<tr>
<td>Implement a Dredging Management Plan to ensure careful spoil handling and minimise release of material to the water column.</td>
</tr>
<tr>
<td>To reduce the risk that stored dredge spoil may be dispersed during winter storms, storage of dredged materials in winter will be restricted within the deepest half of the temporary storage area where practicable.</td>
</tr>
<tr>
<td>An anchor handling survey to identify areas in which anchoring will be permitted will be carried out within the Project Area (including the pipeline corridor where anchoring will take place), the area of which will be calculated by the contractor and agreed with South Stream Transport.</td>
</tr>
<tr>
<td>Chemical additives in the hydrotest solution will be sodium bisulphite, which is of low acute toxicity in the marine environment and does not bioaccumulate. Sodium bisulphite is included by OSPAR on the list of chemical that Pose Little or No Risk (PLONOR) to the environment.</td>
</tr>
<tr>
<td>The microtunnelling drilling fluid will be a mixture of drill cuttings and a slurry made of water and bentonite (a natural, inert, non-toxic clay)) which is pumped through hoses to the tunnel boring machine (TBM) cutting head to lubricate the cutting head. Bentonite is listed in OSPAR’s PLONOR list of additives that Pose Little or No Risk to the environment (PLONOR). OSPAR refers to the Oslo and Paris Conventions for the Protection of the marine Environment of the North-East Atlantic (OSPAR Conventions).</td>
</tr>
<tr>
<td>The exit point for the hydrotest solution will consist of either a four or six inch diffuser positioned approximately 1 m above the seabed and which will reduce the speed of water flow exiting the pipe, thereby reducing turbidity, scour and sediment plumes. The diffuser also acts as an aerator, improving the oxygen concentration in the water and compensating for the scavenging effect of the sodium bisulphite.</td>
</tr>
<tr>
<td>The suction hoses for the hydrotest will be equipped with suitable strainers (2 mm screen mesh). Water will be collected in a break tank (water tank fitted with filter systems) on board the supply vessel. From the break tank, water will be pumped through a filtration skid to remove all particles larger than 50 microns.</td>
</tr>

Design Controls in Project Description

After a successful hydrotest, the Pipeline will be dewatered and chemically conditioned (dried) using Monoethylene Glycol (MEG). MEG will not be disposed into the sea but will be pumped from the subsea test head to the support vessel via a down line, received and stored in suitable secure tanks to be disposed or recycled by an approved waste handling company.

All bunkering activities will be undertaken in accordance with the Vessels and Marine Transport activity-specific CMP, which will be developed as part of South Stream Transport’s Construction Phase ESMP. The CMP will contain activity-specific requirements, to be met by both South Stream Transport and the appointed contractors (and sub-contractors).

All vessel discharges and wastes will be compliant with Marine Pollution (MARPOL) Convention, Bucharest Convention and national regulations, cognisant of the Black Sea’s status as an IMO special area with respect to garbage and wastes containing hydrocarbons. Compliance with national regulations and Bucharest Convention. For information on the regulations governing the discharges of grey / black waste, sewage, garbage, bilge and oily water that will be adopted by the Project (refer Chapter 18 Waste Management).

If a Trailing Suction Hopper Dredger (TSHD) is used, the dredged material will be deposited directly onto the seabed to reduce the dispersion of sediments. It is anticipated that the dredged material will be temporarily stored for approximately two to three months.

Wastes to be offloaded at suitable port / harbour facilities and collected and transferred by appropriately licenced hauliers to licenced disposal sites suitable for the wastes being received.

A project integrated waste management plan will be drawn up to ensure wastes are minimised at source, recycled / re-used where possible and otherwise managed responsibly. Adherence to vessel-specific Waste Management Plans which will include provisions for segregating waste on board, having secure areas for storage of hazardous waste and recycling / reuse where practicable. Any waste water arising from operational maintenance activities (e.g. pigging of pipelines) will be collected on site in tanks and transported from site by an appropriately approved waste haulier to an appropriate waste treatment site in accordance with current waste management regulations.

12.5.2.2 Assessment of Potential Impacts (Pre-Mitigation)

Receptors and their associated sensitivity have been identified above. This section provides an assessment of potential impacts to these receptors using the impact magnitude and receptor sensitivity matrix discussed in Chapter 3 Impact Assessment Methodology. A summary of the impacts identified and their pre- and post-mitigation significance ranking is provided in Table 12.38.

Plankton

Vessel operations will generate waste that may affect plankton as follows:

- Cooling water discharges may cause localised changes in water quality relating to excess heat and the presence of biocides. This may cause thermal and /or chemical stress to biota in the immediate vicinity, though it will be a highly localised effect; and
• Vessel wastes discharges, if highly turbid, may locally reduce light levels and temporarily affect phytoplankton photosynthesis. Suspended solids may also interfere with the filter feeding mechanisms of some zooplankton species and affect the behaviour of visual predators that eat zooplankton.

Vessel wastes will be managed in line with MARPOL and national regulations, thus these impacts are of negligible magnitude to a receptor of moderate to low sensitivity and are therefore assessed as **Not Significant**.

Plankton may be affected by the re-suspension of sediments (particularly associated with dredging and nearshore storage of dredged spoil) that reduces photosynthesis, interferes with filter feeding and alters the rate of visual predation on plankton.

Dredging or dumping at the microtunnel exit pits results in the formation of a sediment plume after dredging works start. The sediment plume drifts in the direction of the ambient currents along the Russian coastline. When assessing the impact to plankton of suspended solids, a threshold of 10 milligrams per litre (mg/l) is usually applied\(^\text{17}\). Plume modelling (see Appendix 12.2) using conservative criteria predicts that the impact area for this threshold is 16.2 km\(^2\). It should be noted that this is very much a worst case scenario, as it does not allow for flocculation and other processes that will tend to remove material from suspension rapidly. In reality, sediment in water tends to form density flows that sink rapidly. A range of studies conducted since the 1990s have shown that sediment discharges into the marine environment will tend to form a density current and flow near-instantaneously to the seabed (convective descent), carrying most of the turbid body rapidly to the seabed. There, it dynamically collapses to form a horizontally moving turbid near-bed layer from which the solids content reconsolidates onto the seabed. A percentage of this descending flow (of the order of a few per cent of the solids by weight) will mix with the ambient water mass during the descent and form a more slowly dispersing far-field plume. Another factor that increases the settling rate of suspended sediments and reduces the extent of surface plumes is the tendency for fine material to flocculate. When factoring in these mechanisms of flocculation and convective descent, the extent of the surface plume is very significantly decreased. The area encompassed by the plume (at concentrations over 10 mg/l) is predicted to be in the order of 0.22 km\(^2\) and will extend approximately 700 m from the source. The significance of this is that, because of natural flocculation processes, the plume will not impinge on the Utrish SPNA marine reserve.

The maximum area of the surface plume for offshore seabed interventions is predicted at 4.7 km\(^2\) while, because of the tendency of most suspended particles to sink, the near bed plume is significantly larger, possibly covering an area of 150 km\(^2\).

Despite the fact that sediment plumes may extend for an appreciable extent, they are transitory phenomena, and most dense near the seabed, that will only affect a very small proportion of the plankton, negligible in the context of natural population variability and predation. This is likely to be a short-term negligible magnitude to a receptor of moderate to low sensitivity, generating a **Not Significant** impact.

\(^\text{17}\) 10 mg/l is the recommended Maximum Permissible Concentration (MPC) for suspended solids for Russian seawater shelf zones.
Hydrotesting the Pipeline will involve seawater abstraction and discharge of hydrotest solution, containing oxygen scavenger. The discharge will comprise approximately 8,000 m$^3$ of seawater containing 250 parts per million (ppm) of sodium bisulphite, which is a non-toxic substance and on the OSPAR List of substances used and discharged offshore which are considered to Pose Little Or No Risk to the environment (PLONOR). The discharge will be essentially non-toxic and take place approximately 1 m above the seabed. Subsequent cleaning and drying may also involve the discharge of solid wastes and drying agents, although these will be recovered and disposed of on land. This impact is likely to be a short term negligible magnitude to a receptor of moderate to low sensitivity, leading to an impact that is **Not Significant**.

Seawater abstraction may result in the entrainment of plankton. These will be subject to physical stresses and may result in mortality. However, as only a very limited number of localised individuals will be affected this is a short term negligible magnitude to a receptor of moderate to low sensitivity. The impact is thus **Not Significant**.

Light from night-time works may result in changes in the vertical distribution of plankton however, as this is localised, it will be of negligible magnitude to a receptor of moderate to low sensitivity. The impact is thus **Not Significant**.

**Benthos**

Vessel wastes may affect benthic communities in a variety of ways:

- Suspended solids in vessel wastes may locally reduce the photosynthetic ability of marine macrophytes. Particles may also interfere with the filter feeding mechanisms of some invertebrates. Settling material, if present in appreciable quantities, may smother benthos in shallow water. The volume of suspended material from vessel waste is likely to be low so that the magnitude of the impact is low; and

- Decomposition of organic material in kitchen wastes, grey water etc. may locally reduce dissolved oxygen levels, causing physiological stress, displacement and/or behavioural changes in benthos.

Vessels must be compliant with the requirements of MARPOL when discharging wastes to the marine environment and are prohibited from discharging within 3 NM of the shoreline.

The above are negligible magnitude events to a receptor of moderate to high sensitivity (in the case of seaweed stands) that will generate, at most, **Low** significance impacts prior to mitigation.

Seabed disturbance may occur through several different activities, including surveys and inspections, obstacle removal (“pre-sweeping”), dredging, pipe-laying, post-lay trenching and rock placement / seabed intervention. This is the most significant aspect associated with the Project, potentially affecting large areas of the seabed and associated species and habitats, as detailed below. Impacts to benthos are significant not only from the perspective of biodiversity, but also the ecological processes that benthos provides, namely primary production, nutrient cycling and biofiltration.

The Project may generate dredged spoil from offshore trenching and profiling. Dredged spoil in the nearshore (i.e. from the dredging of the microtunnel pits and transition trenches) will be
temporarily stored in designated offshore storage areas. This material will be subsequently re-
dredged and used for trench backfill following pipe installation. A certain amount of offshore
dredged material (estimated volume of 42,500 m³) may be disposed of at an existing
underwater disposal site (no. 923, located on the Russian continental slope, see Figure 12.2 for
location). In the event that any dredge spoil is identified as contaminated or requires disposal
on land, the spoil will be treated as construction waste and appropriately stored, transported
and disposed of (see Chapter 18 Waste Management). However, baseline studies
undertaken to date do not indicate that this is likely.

When the TBM emerges into the microtunnel exit pit, there will be a small discharge of slurry
into the marine environment, comprising rock particles and a natural clay mineral, bentonite.
Bentonite is listed in OSPAR’s PLONOR list of additives that Pose Little or No Risk to the
environment. However, this will be carefully controlled by reducing the pressure of slurry
supplied to the TBM on nearing emergence to the exit pit and immediate shutdown of the TBM
slurry circuit when the TBM emerges into the exit pit. Since bentonite is denser than seawater,
the slurry will tend to settle on the seabed rather than mix with the surrounding water column.
Furthermore, the depth of the exit pit (approximately 6 m below the natural seabed surface)
will reduce the exposure of the slurry to seabed currents and will capture the majority of slurry
discharged from the tunnel. It will therefore not have any significant impact on benthos.

Benthos will be directly impacted by substrate loss that will cause some direct mortality in the
nearshore dredged area. Approximately 0.85 ha of seabed will be dredged for the microtunnel
exit pits and short lengths of buried pipeline to approximately 26 m isobaths. Temporary
storage of dredged spoil will occupy a nominal 10 ha (based on a dredged volume of
approximately 100,000 m³). This will impact a coarse sediment community characterised by
burrowing bivalves such as Gouldia minima and Chamelea gallina. Further offshore, 5.3 ha of
seabed will be pre or post trenched for stability reasons, and another 13.1 hectares (ha) subject
to rock backfill and dumping for protection, in an area of mud dominated by bivalves such as
Parvicardium similis and Modiolula phaseolina. The total area directly affected by these activities
is thus estimated at approximately 29.25 ha. The unburied pipeline will also impact
approximately 1,350 ha (13.5 km²) of seabed (assuming a 60 m bundle width over 225 km),
causing disturbance and re-suspending sediments, the majority of which will be in the anoxic
deep sea and not affect any macrobenthic communities.

Disturbance from pipe-lay vessel anchors and chains is predicted to affect approximately 6.3 ha
per kilometre of laid pipeline in deeper water (up to 600 m water depth). For each anchoring
point, it has been assumed that a conventional anchor spread of twelve 20 to 25 tonne anchors
will be used with an average chain length of 200 m. The total seabed affected by anchoring will
therefore be approximately 190 ha (1.9 km²) affecting soft substrate benthic habitats and deep
sea microbial benthic communities. Given the limited extent of the seabed disturbance and the
ability of soft benthic habitats and associated fauna to withstand and recover from physical
perturbation, the magnitude of the impact is assessed as low on a receptor of moderate
sensitivity, resulting in an impact of Low significance prior to mitigation. Deep sea microbial
communities are of low sensitivity, and there is a limited seabed footprint so impacts are
considered of Low significance prior to mitigation. However, the Project is committed to
undertaking an anchor corridor survey with the aim of identifying and avoiding or minimising
disturbance to sensitive habitats including establishing exclusion zones where practicable.
In addition to direct seabed loss, resettling of suspended solids and increased turbidity may cause some smothering resulting in direct mortality as well as impairing the ability of some organisms to feed, respire and photosynthesize.

Modelling has been carried out to assess the extent of the plume from seabed intervention works. As previously described, the flocculation of material and the formation of density flows tends to make sediment plumes sink rapidly, thus the seabed impacts may be greater than the near-surface impact. Seabed works associated with dredging and storage of material at the microtunnel exits are predicted to cause a plume in excess of 10 mg/l that covers approximately 0.2 km². Plumes will disperse to background levels in 60 to 120 hours depending on wind and current direction. In the context of seaweed photosynthesis, this is considered a negligible level impact on a high sensitivity receptor, generating impacts of **Low** significance prior to mitigation.

Convective descent of turbid plumes carries most of the material rapidly to the seabed forming a horizontally moving turbid near-bed layer from which the solids reconsolidate onto the seabed. Typically the bulk of the material accumulates in an annular area on the seabed with a diameter 1 to 3 times the water depth. The deposit is lenticular, with decreasing deposition thickness at the edge. From the perspective of ecological impacts, different organisms can tolerate various levels of smothering. Seaweed stands are sensitive to relatively thin layers of sediment reducing their photosynthetic ability, though as they grow in shallow water, re-suspension by wave action tends to limit the build-up of sediments. Dense algal cover in the Project Area is generally confined to water approximately 10 m deep or shallower, with sparse cover between approximately 10 and 20 m and burrowing bivalve communities beyond this depth. At 10 m water depth, waves 1 m high and 5 m long will generate near-bed orbital velocities of 0.15 metres per second (m/s⁻¹), sufficient to re-suspend fine sand and recently deposited muds (Ref. 12.34). Such conditions occur regularly and wave maxima generated by storm events are even capable of initiating motion in fine sediments to 40 m depth, thus resettling sediment will not persist or accumulate.

Modelling shows that the area of seabed likely to experience more than 5 mm of deposition is limited to approximately 35 to 46 ha depending climatic conditions, approximately half of which will be landward of the tunnel exits where seaweed communities are prevalent (see Appendix 12.2 for further details). Much of this will be rapidly re-suspended and transported away by wave action. The region’s overall integrity in terms of community structure and the ecological processes that benthic communities provide will not be impacted, though some ecological features will be affected on a local scale. Given the temporary nature and relatively limited areal extent of seaweed beds affected, this is considered a low level impact on a high sensitivity receptor, generating impacts of **Moderate** significance prior to mitigation.

Infaunal benthic invertebrates in soft substrate habitats are generally better able to tolerate sediment deposition and a threshold of 5 cm is commonly applied (Ref. 12.35). Tunnel exit works are predicted to cause this level of deposition over approximately 5 ha. The maximum deposition thickness for offshore seabed interventions is not predicted to exceed this threshold and there are no changes to sediment type expected. Because of the very small area impacted, this is considered a low level impact on a moderate sensitivity receptor, generating impacts of **Low** significance, prior to mitigation.
Minor disturbance associated with pre-construction route surveys, crossings etc. are negligible magnitude activities that will have a **Not Significant** impact prior to mitigation.

Hydrotest discharge may result in localised deterioration of water quality (due to low dissolved oxygen concentration), alteration of hydrodynamic regime and resultant seabed disturbance. However the discharge will only contain sodium bisulphite which is classified by OSPAR as PLONOR (poses little or no risk), thus no chemical effects are anticipated. The discharge structure itself will be elevated at least 1 m above the seabed to reduce re-suspension of sediments and will take place beyond the depth where sensitive seaweed communities are present. Effects will therefore be temporary and localised, and no appreciable long or medium changes will accrue to benthic communities as a result. This is thus considered a short-term and negligible magnitude impact to a receptor of moderate sensitivity, which means a **Not Significant** impact prior to mitigation.

**Fish**

Vessel operations have the following potential impacts on fish:

- Decomposition of organic material in uncontrolled disposal of kitchen wastes etc. may locally and temporarily reduce dissolved oxygen levels, causing physiological stress, displacement and/or behavioural changes in fish; however as the Project will comply with MARPOL discharge controls this will not arise in reality. Conversely, kitchen wastes may attract some species to feed though the scale of this effect is likely to be trivial; and

- Cooling water discharges may cause localised changes in water quality relating to excess heat and the presence of biocides. This may cause thermal and/or chemical stress to biota in the immediate vicinity, though it will be a highly localised effect.

The above effects are considered negligible therefore any associated impact is **Not Significant** to fish.

Light from night-time works may affect fish, either by direct attraction or through alterations in the distribution of planktonic prey. Because of its highly localised nature, this is a negligible magnitude impact to a moderate to high sensitivity receptor, thus at most of **Low** significance prior to mitigation.

The impact of dredging, pipe-laying and seabed intervention on fish will be variable depending on their habit, habitat and life stage. Open water pelagic species will be essentially un-impacted as they can readily avoid noise sources and are not prone to the effects of near bed sediment plumes or seabed deposition, while small, benthic dwelling species may be more severely impacted (on a localised scale) through habitat loss, loss of food resource and smothering. High concentrations of suspended solids associated with dredging plumes may cause damage to gills in some cases, while in others may help avoid predation, though the latter is a more transient effect. As previously mentioned, sediment plumes generated by seabed intervention will be of limited extent (relative to the overall habitat and distribution range) and duration, as will areas of significant seabed deposition. In some cases, seabed disturbance is attractive to fish as it exposes infaunal prey that might otherwise be inaccessible. Moderate levels of turbidity are also beneficial to some species in avoiding visual predators, though the scale of such effects will be small. The impact of seabed disturbance to fish is likely to affect a localised proportion of the
population for less than one generation at any given location and is thus a negligible to low magnitude impact to a receptor of moderate to high sensitivity resulting in, at most, **Moderate** significance impacts prior to mitigation. With respect to pelagic fish offshore, the impacts will be **Not Significant**.

Noise and vibration will be generated by several Project Activities, including the passage of vessels, microtunnelling in the nearshore, dredging, trenching, pipe-laying and rock placement (see Appendix 12.3). Low levels of noise may also be generated during commissioning, testing and operational flow. Fish may be either hearing specialists or hearing generalists; the former are usually species with swimbladders that are connected to the ear and are more sensitive to noise. Black Sea shad (*Alosa maetica*), Caspian shad (*A.caspia*), sprat (*Sprattus sprattus*), kilka (*Clupeonella cultriventris*) and anchovy (*Engraulis encrasicolus*) possess specialised gas ducts extending to the inner ear and are hearing specialists. Hearing generalist fish (such as sturgeon, turbot, and skate) are less sensitive both in terms of sound level and frequency range.

Acoustic impact analysis showed that sound levels generated by pipe-laying and trenching in the Black Sea are insufficient to cause mortality or injury to fish. The approach used is based on criteria developed by Stadler and Woodbury from hearing studies of fish exposed to airgun sounds (see Appendix 12.3 for further details). This is most commonly applied to pile driving injury range estimation but can be reasonably applied to continuous sound. Exposure to a few loud sounds is more damaging to fish than exposure to a larger number or longer duration of quieter sounds therefore, the use of the Stadler and Woodbury criterion (187 dB re µPa²s) is precautionary when applied to exposure to continuous sound and yields very conservative estimates of effect range and area.

Modelling results show a theoretical maximum injury effect range of 0.9 to 1.6 km, corresponding to an effect area of 5 to 6.8 km² (Appendix 12.3). It should be noted that this is a very conservative estimate, as much vessel noise is high frequency and fish generally have no sensitivity to high frequency sound with the exception of some fish specialised in hearing very high frequency sound, such as cod which are not present in the Black Sea. In addition, fish will move away from loud noises and their actual exposure in reality will be significantly less.

Weighted metrics, specifically the dBₚₜₜ technique, are based on the hearing sensitivity of the target species and the loudness of the noise as experienced by the animal. Using weighted thresholds, it was found that behavioural effects (given by the 75 dBₚₜₜ threshold) may be apparent in some hearing specialist fish such as sprat or kilka in some situations¹⁸ (though not shad or anchovy). Anchor handling is the activity most likely to generate such responses, and in shallow water may extend up to 260 m from activity, with an affected area of approximately 0.2 km². In deepwater, where anchor handling will not take place, the pipe-laying vessel itself may generate similar impacts at a lesser range of approximately 140 m (area of effect approximately 0.06 km²). No impacts are predicted to hearing generalist species.

---

¹⁸ Audiograms for sprat and kilka were not available for use in the modelling exercise and herring, a close relative, was used as an analogue. Given that anchovy are also closely related and no impacts are predicted based on the anchovy audiogram, the use of herring in the model may have resulted an over-estimation of impact ranges.
Because noise will affect a localised group of individuals over a short time period, and because there are no protected species that are hearing specialists, the generation of noise is considered a medium term, low magnitude impact on a receptor of moderate sensitivity of Low significance. Additional detail of the acoustic modelling is provided in Appendix 12.3.

Seawater abstraction for hydrotesting may result in the entrainment of small fish. These will be subject to physical stresses and some mortality. Larger fish may also be impinged in the intake structure, undergoing physical trauma, but only a very limited number of localised individuals will be affected. This is likely to be a short term low magnitude impact on a receptor of moderate to high sensitivity. The significance of the impact is thus Moderate significance prior to mitigation.

Hydrotesting will involve the limited discharge of seawater containing no more than 250 ppm sodium bisulphite, which is classed by OSPAR as PLONOR. While not toxic, this water may have reduced oxygen content and thereby result in some respiratory stress to fish in the immediate vicinity. Effects will nonetheless be highly localised and restricted to only a few individuals within the population. No appreciable changes will accrue to the community as a whole. This effect is thus considered short term impact of negligible magnitude on a receptor of moderate to high sensitivity. The significance of the impact is thus Not Significant prior to mitigation.

Seabirds

Vessel movements during mobilisation, surveying and pipe-laying activities have the potential to temporarily disturb seabirds. However, these are highly mobile animals generally able to avoid areas of disturbance, and the density of seabirds at sea is generally low, though occasional dense flocks of both Mediterranean shearwaters (Puffinus yelkouan) and great crested grebe (Podiceps cristatus) have been observed near the coast. This will thus be a low magnitude impact to a receptor of moderate to high sensitivity, leading to impacts of Moderate significance prior to mitigation.

Seabirds will not be directly affected by trenching etc. Indirect, short term effects may occur to a localised part of the population as a result of displacement or loss of prey in the nearshore. This is considered a negligible magnitude impact to a receptor of moderate to high sensitivity, leading to Low significance impacts prior to mitigation.

There will be occasions where night-time works are required necessitating the use of floodlights. Light can affect migrating birds and cause mortality from bird strikes on highly illuminated offshore installations. The source of illumination (the pipe-laying vessel spread) will be transient at any given location and have limited scope to interact with night-flying birds. Because only a small number of localised individuals will be affected, this is considered a short term low magnitude impact to a receptor of moderate to high sensitivity, resulting in impacts of Moderate significance at most prior to mitigation.

Marine Mammals

Vessel movements during mobilisation, surveying and pipe-laying activities have the potential to temporarily disturb marine mammals. Collisions may also occur. However, these are highly mobile animals with acute sensory perception and are generally able to avoid areas of disturbance and only a few individuals are likely to be affected, if any. This will therefore be a
medium term, low magnitude impact to a high sensitivity receptor, leading to impacts of \textbf{Moderate} significance prior to mitigation.

Cooling water discharges and other effluent streams from vessels may cause localised changes in water quality relating to excess heat and the presence of biocides. This may cause thermal and/or chemical stress to animals in the immediate vicinity, though it will be a highly localised effect and easily avoided by cetaceans, thus this is a negligible magnitude impact to a high sensitivity receptor, leading to impacts of \textbf{Low} significance.

Light from night-time works may affect marine mammals through alterations in the distribution of prey. Because of its highly localised nature and its potential to only impact a very limited number of individuals, this is a negligible magnitude impact to a high sensitivity receptor, likely to be \textbf{Not Significant} prior to mitigation.

Marine mammals are less impacted by seabed changes or sediment suspension than fish or benthos, as they are air breathing and do not rely exclusively on sight for navigation or feeding. However, indirect effects from the displacement of their food resource may occur. The effects of seabed disturbance on marine mammals are short term and will only affect a few individuals thus it is a negligible magnitude impact to a high sensitivity receptor, of \textbf{Low} significance prior to mitigation.

Noise from vessel movements, pipe-laying and trenching can negatively impact marine mammals as it influences their ability to echolocate, communicate and can cause physical harm (through risk of disorientation leading to beaching, as well as in extreme cases, trauma to the auditory apparatus). Noise can cause certain cetacean species to vacate feeding areas, as it interferes with acoustic prey location.

A number of activities involve the generation of man-made sound underwater and this has the potential to impact cetaceans. The noise-generating activities associated with the Construction and Pre-Commissioning Phase have been identified as:

- Pre-lay sonar surveys;
- Vessel movements;
- Microtunnelling,
- Trenching;
- Rock placement;
- Pipe-laying; and
- Pre-commission testing.

Detailed noise modelling has been carried out to assess the potential impact underwater noise will have on cetaceans. The noise modelling has included consideration of single sources, combined sources (from vessel spreads) as well as cumulative exposure over time (24h). The potential of noise to cause injury or behavioural alterations has been assessed and is summarised below. Full details are provided in Appendix 12.3.

In keeping with the latest scientific approaches, injury effects assessment has been based on the cumulative sound exposure level (SEL) over a period of 24 hours. The pipe-laying operation
(loudest among any possible activities at the three representative sites) has been modelled including realistic motion of pipe-lay vessel and support vessels such as pipe carrier ships shuttling to resupply (Appendix 12.3). Two sets of criteria are available and currently considered valid for the assessment of ranges to injury\textsuperscript{19} from continuous noise: the Southall et al. criteria and the Finneran and Jenkins criteria (also referred to as the “US Navy criteria”):

- The former uses a single threshold of 215 dB re µPa²-s SEL weighted according to the hearing class of the subjects using Type 1 weighting curves (M-weighting); and
- The latter uses variable thresholds and newer Type 2 weighting functions that take into account subjective loudness and some additional data collected since the Southall et al. study. For Mid Frequency cetaceans (MFC) such as dolphins the threshold is 198 dB re µPa²-s SEL with Type 2 MFC weighting. For High Frequency cetaceans (HFC) such as porpoises the threshold is 187 dB re µPa²-s SEL with Type 2 HFC weighting.

The results of the SEL based assessment have been presented in terms of the modelled area exposed to cumulative levels above the threshold over a 24 hour period (area of effect), as well as a range of effect that provides a linear “width” of the footprint relative to the main pipe-lay vessel. Because of the irregular and elongated shape of the cumulative footprint along the pipe-lay route, the effect range cannot be computed as a radius for equivalent area and is instead measured from the swath width of the footprint with suitable consideration of its shape. The injury footprint of the operations is estimated to be very limited. Porpoise in close proximity to pipe-laying (20 to 60 m) may experience PTS, corresponding to an impact area of 0.6 to 1.3 km².

Various criteria are available to assess the potential impacts of underwater noise on cetacean behaviour. Traditionally an un-weighted criterion for behavioural effects onset at 120 dB re µPa has been used commonly referred to as the “Level B Harassment” criterion. This approach, in use in the USA since 1997, has several acknowledged shortcomings, most importantly that marine species vary widely in their sensitivity to sound, and especially to the frequency range which they hear. Thus this “one size fits all” criterion is considered inappropriate in some specific instances and the approach is currently under review by NOAA/NMFS\textsuperscript{20} (Ref. 12.36). It should not be totally ignored or dismissed out of hand however, due to its current widespread use. It is therefore included here for completeness and reference to common practice. It is also a criterion still cited as the only acceptable approach for the harbour porpoise by studies as recent as 2012\textsuperscript{21} that explicitly exclude the use of weighted metrics criteria for that species because of its unique susceptibility and reaction to sound stimuli.

Weighted metrics behavioural criteria for species other than harbour porpoises could be considered, but their applicability in the case of continuous sounds such as those from vessels is

\textsuperscript{19} Defined as the onset of permanent threshold Shift (PTS); i.e. the point at which hearing may become impaired and from which the animal cannot recover.

\textsuperscript{20} The new approach, currently undergoing peer review, is an attempt to create a more nuanced scientific set of criteria. It is likely to result in either an increase in the Level-B threshold, based on the understanding that animals will tend to avoid noise sources thereby reducing their exposure, or to be related more closely to ambient noise levels in the marine environment. These new guidelines are due to be issued in the near future.

\textsuperscript{21} Criteria And Thresholds For U.S. Navy Acoustic And Explosive Effects Analysis
not confirmed and the relatively high reaction thresholds that arise from their use would be
difficult to defend by comparison with empirical evidence.

Audiogram based behavioural effect were chosen as the most defensible criteria given the
availability of reliable audiograms for dolphins. There remains a degree of uncertainty in the use
of audiogram referenced levels (dB relative to hearing threshold, or dB\text{ht}) regarding which
threshold to adopt for the onset of behavioural disturbance. A commonly used set of criteria are
the fixed thresholds of 75 and 90 dB\text{ht} for all species as onset of mild and pronounced
behavioural reactions respectively. However validity especially of the higher threshold has been
questioned and evidence can be found for reaction at significantly lower levels. Taking the
different elements into account, the 75 dB\text{ht} threshold is considered a reasonably conservative
and defensible estimator of the onset of behavioural disturbance in cetaceans and has been
used for this assessment.

Based on audiogram weighted criteria, behavioural effect ranges for individual vessel operations
are only estimated to be significant for dolphins and porpoises with effect ranges never
exceeding 1.5 km at any modelled location. A summary of the predicted ranges and areas of
effect is presented in Table 12.36.

Unweighted metrics predict behavioural impacts over a wider range; up to 46.7 km for a pipeline laying spread with anchor handling vessels in shallow water, but as previously discussed, this is considered highly conservative and actual impact ranges may well be less than this.

In addition, cetaceans may be exposed to sonar noise during pipeline inspection. There are well accepted impact criteria for sonar sources that are based on the instantaneous root-mean-square sound pressure level metric (rms SPL). For injury, a generic (NMFS) standard threshold of 180 dB re 1 µPa un-weighted is commonly used. For behaviour effects, there are US Navy criteria specifically for sonar sources. Their criteria for mid-frequency and high-frequency cetaceans are based on Type I weighting of the SPL and do not provide a single threshold value but rather refer to a Behavioural Response Function (BRF) that assesses the probability of a behavioural impact from a given SPL. Accordingly, a reasonably precautionary 25% probability of response to a weighted SPL of 160 dB re dB re 1 µPa has been used as the principal criterion. However, as previously explained, harbour porpoises are excluded from this criterion due to the high susceptibility to disturbance of this species and the recommend NMFS standard threshold of 120 dB re 1 µPa un-weighted is used. In all cases, cetaceans would need to be closer than 10 m to the source for any possibility of injury. The longest range predicted impacts are approximately 1 km from the source, specifically to porpoises in mid-depth waters. Behavioural impact ranges to other cetaceans from sonar are consistently less than 250 m. The ranges over which behavioural impact might be observed are summarised in Table 12.37.

The analysis shows that sound levels generated by pipe-laying, trenching and associated activities are unlikely to cause significant injury to marine mammals. Though there is the potential for PTS very close to vessel spreads, in reality it is unlikely that cetaceans will approach loud sound sources. Noise will affect a group of localised individuals over a short time without affecting the overall population, thus the generation of noise is considered a medium term, low magnitude impact to a high sensitivity receptor, of Moderate significance prior to mitigation.

Additional details of the quantitative underwater noise assessment can be found in Appendix 12.3.

Cetaceans may be exposed to hydrotesting discharge, but as it is non-toxic, the only impact will be secondary due to possible localised displacement of prey. This is a short term negligible magnitude impact to a high sensitivity receptor, giving a Not Significant to Low significance prior to mitigation.

12.5.2.3 Mitigation and Monitoring

A wide variety of mitigation measures can be applied to minimise or otherwise reduce the construction and pre-commissioning impacts of the Pipeline. Mitigation will be applied at different stages in the Project to minimise impacts and to reflect GIIP. A significant part of the mitigation is achieved through design (e.g. nearshore microtunnelling, see Table 12.35 for design controls) to prevent impacts occurring.

Additional management measures will be implemented as necessary to reduce the impact to a level of a practical minimum. These are discussed below and are grouped by each potential impact arising from the Project Activities in Table 12.27.

It is important to note that impact categories may cover a broad range. For example a moderate impact could be relatively localised and affect a limited set of receptors, or approach the threshold of breaching a regulatory limit. Clearly to design an activity so that its effects only just avoid a major impact is not good practice thus the emphasis for mitigation is on
demonstrating that the impact has been reduced to practical minimum, rather than necessarily be reduced purely in terms of its rating.

**Disturbance / Injury of cetaceans, seabirds and fish**

- Vessel speed will be reduced where seabirds on the water surface and/or marine mammals are known to be present, and vessels will not approach animals unless it is not possible to avoid doing so;

- Specific protocols for mammal and bird interactions will be drawn up in a contractor’s management plan and qualified (e.g. Joint Nature Conservation Committee registered course or equivalent) Marine Mammal Observers (MMO) will be present during pipe-laying operations to assist in managing such interactions on a case by case basis. This plan will specify the number, location, deployment and procedures to be used;

- Vessel engine power will be “ramped” up where practicable, to allow cetaceans that may be nearby to move away from sources of loud underwater noise and vibration;

- Appropriate lighting design during night-time works will be implemented, including use of directed illumination, screens, shades, timers, actuators, etc. as required. Skyward and seaward light projection will be eliminated as far as safe and practicable, by removing unnecessary illumination, reduction of light intensity and shielding of light sources during the night, and in low visibility and bad weather conditions. This will apply particularly during the most active migration period for migrating birds (between the end of March and the end of May, as well as mid of September to the end of October);

- Intake screens for water abstraction will be used to prevent ingress of fish and large invertebrates. The design of screens should be optimised to minimise injury and/or mortality;

- Water intakes will be designed to minimise seabed disturbance and impingement or entrainment of marine organisms by appropriate positioning and reduction of the velocity of the intake;

- The hydrotect water intake will be fitted with appropriate screens to minimise entrainment of organisms;

- Limit activities to be carried out within the “coastal offshore environment” defined as the continental shelf out to 25 km along the pipeline route during May in order to avoid any disturbance to fish spawning;

- Preparation of a Biodiversity Action Plan (BAP) and a Biodiversity Management Plan (BMP)\(^{22}\); and

- Use of modern vessels and plant and undertaking of regular maintenance checks.

---

\(^{22}\) According to IFC guidance (GN6), a BAP consists of any number of biodiversity-related actions that need to be carried out by a company to fulfil the needs of a particular requirement, request or expectation (e.g., Lender compliance, legal requirement, stakeholder concerns), particularly if the EISA process has identified information gaps that need to be filled. A BMP should be developed when the baseline, impact assessment and proposed mitigation measures are complete and the only remaining issue is to collate such information into one implementable and auditable Management Plan.
Changes to Water / Sediment Quality

- A Project integrated waste management plan will be drawn up to ensure wastes are minimised at source, recycled / re-used where possible and otherwise managed responsibly (see Chapter 18 Waste Management);
- If biocides or other additives are required in the cooling water system, or for general cleaning purposes any chemical additives should be selected on the basis of least risk to the environment and will not contain carcinogenic, mutagenic or reprotoxic components;
- Intakes will be positioned or oriented to minimise seabed disturbance;
- Intake screens will be used to prevent entrainment of fish and large invertebrates. The design of screens should be optimised to minimise injury and/or mortality;
- Where dredging is required, the choice of dredger will be made to minimise sediment resuspension (within engineering constraints). A chute, to deposit sediment close to the seabed to minimise turbidity will be used. Additional turbidity reduction measures will be used where practical, particularly where sediment is to be temporarily re-deposited in nearshore storage areas; and
- Implement a Dredging Management Plan.

Seabed disturbance / Habitat Loss

- Dredging areas are contained within the maritime safety exclusion zone, and variables such as dissolved oxygen, suspended solids, and/or accretion rates will be monitored at defined distances from the dredging activities to verify that excessive sediment suspension is avoided;
- Overspill from dredgers or barges will be avoided;
- Cooling water discharges from the pipe-laying vessel should be operated to achieve maximum dispersion;
- Dewatering pipe orientation, diffuser design and discharge velocity will all be optimised to achieve maximum dispersion and minimal seabed disturbance from pipeline dewatering. Discharge will be through a four or six-inch diffuser positioned approximately 1 m above the seabed, to reduce the speed of water flow as it exits the pipe in order to reduce turbidity and possible creation of sediment plumes;
- Pumped discharge of sediment back in to the trenches will be carefully targeted with the outlet as close as practicable to the trench bottom to ensure the majority of sediment is contained within the trenches; and
- Rock placement and seabed intervention will be kept at the practical minimum to ensure pipeline stability and safety. This also has the benefit of minimising impacts to sensitive biotopes.

Monitoring

Ecological monitoring is necessary to verify the predicted impacts of pipeline installation, to demonstrate the efficacy of mitigation and to document the recovery of impacted receptors.
from temporary impacts. Monitoring programmes will be designed to interface with surveys carried out for the Project, to ensure inter-comparability of pre and post-construction data.

An environmental monitoring plan has been developed for the Russian national EIA process, as required by Russian regulations, comprising construction and post construction monitoring of water, sediments, plankton (including phytoplankton, zooplankton and ichthyoplankton), benthos, fish, birds and mammals. The precise details (e.g. location of sampling stations etc.) may need to be revised in future, but in principal, this will form the basis for monitoring in the Russian sector. If impacts are detected during construction, additional post-construction monitoring will be developed by the Project. Monitoring may be required not only for the receptor but also the Project aspects that have the potential to generate impacts. Monitoring will therefore comprise:

- In-field monitoring of relevant receptors; and
- Monitoring of the implementation (and therefore effectiveness) of mitigation measures and management controls.

The ESIA Report has identified the following key components for which monitoring will be required.

- Water column monitoring: In order to verify the predicted impacts of sediment re-suspension, a variety of physical and chemical parameters, including but not limited to suspended solids and pollutants, will be monitored during and post-construction;

- Sediment monitoring: Key sediment characteristics will be monitored during and post construction to verify the predicted seabed impacts. Parameters will include geological and ecological variables such as particle size distribution and the presence of hydrocarbons and heavy metals;

- Plankton: Plankton monitoring is stipulated in the Russian EIA Report, though this ESIA Report has determined there is no scope for significant impacts. Nonetheless, such monitoring may have some value in better understanding the variability of the receiving environment;

- Benthic communities: Monitoring of benthic communities is fundamental to the Project’s Overarching Environmental and Social Monitoring Programme, as this is the principal marine ecological receptor. Monitoring during and post-construction will allow verification of predicted impacts and an assessment of the degree and speed of recovery of impacted areas. Monitoring will also be designed to account for seasonality and be of sufficient duration to allow for longer term variations;

- Fish: Monitoring of fish populations during and post-construction will be carried out to determine the state of local populations. Species of conservation importance, including rare and endemic species and subspecies are of particular interest in this regard;

- Seabirds: Monitoring of seabird distribution during and post-construction will be carried out to determine the state of local populations and their distribution. While the Russian EIA Report stipulates monitoring during construction, additional longer term research will deliver a greater understanding of the status of seabird populations and the importance of the Project Area to them; and
• Marine Mammals: Monitoring of cetaceans during and post-construction will be carried out to verify the extent of impacts, particularly with respect to underwater noise. Because of their conservation status, additional research–based monitoring is appropriate (see below).

Biodiversity monitoring will be integrated into the Project’s overall Environmental and Social Management System (ESMS). In this way, the results of the program can be clearly linked to management actions and the results used to evaluate the effectiveness of its mitigation strategy. This is in line with IFC Performance Standard 1, which emphasizes a “plan, do, check and act” management system. Further detail is provided in the Project’s Environmental and Social Management Plan (ESMP) described further in Chapter 22 Environmental and Social Management.

In addition, because critical habitat has been identified for certain pelagic fish, seabirds and cetaceans, there is an additional requirement for biodiversity monitoring. South Stream Transport’s mitigation strategy, which will be designed to comply with IFC PS6 and to achieve net gains, must be described in a Biodiversity Action Plan (BAP). Once a sufficient Biodiversity (or Ecological) Management Plan (BMP) is in place, that adequately describes on-site mitigation measures, the BAP need only describe the plans to achieve net gains. One of the common ways in which projects deliver biodiversity benefits is the use of offsets. However, in this instance, where a biodiversity offset is not part of the mitigation strategy (partly due to the absence of significant residual impacts, and partly due to the difficulty in securing a marine offset), net biodiversity gains will be obtained by identifying additional opportunities to enhance habitat and protect and conserve biodiversity. The implication of this for the Project’s Overarching Environmental and Social Monitoring Programme, particularly for fish, birds and mammals, is that it must be appropriately designed to meet research objectives that enhance knowledge to the point that conservation measures can be tangibly improved. The scope of such programmes will be developed in consultation with relevant parties to ensure the maximum benefit is delivered.

The Project will produce a Biodiversity Action Plan (BAP) which will include the mitigation strategy for identified critical habitats. The BAP is currently being produced and will include all relevant parties and stakeholders identified to help achieve net gain. Further information on the likely scope and implementation of the monitoring programme is provided in Chapter 22 Environmental and Social Management.

12.5.2.4 Residual Impacts: Construction and Pre-Commissioning

The residual impacts of the Project Construction and Pre-Commissioning phases are detailed in Table 12.30. Mitigation designed into and applied to the Project will reduce the majority of impacts to marine ecological receptors to Low or Not Significant. Not significant impacts relate either to very localised and infrequent activities, or to those impacts that are within the limits of the natural variability of the system and thus effectively undetectable. These impacts, which are not considered further, comprise the following:

• Seawater abstraction for cooling water purposes will have no appreciable impact on sensitive receptors;
• Any disturbance arising during inspection surveys etc. is of a very small spatial extent and duration and is thus insignificant. The same holds true for maintenance inspections of the operational Pipeline;

• Installation of test heads is a brief activity of very limited spatial extent and involves no appreciable discharges or disturbance;

• Turbulence from dynamic positioning of vessels will be localised to such a degree that the impact will be insignificant; and

• Disturbance and waste generation from a series of small scale, brief construction activities such as welding of well heads, raising pipe ends for tie-ins etc. are not significant.

A conservative and precautionary approach has been adopted in this assessment leading to some possible exaggeration of the significance of potential impacts, in order to ensure that sensitive marine ecological receptors are protected as far as practicable. Nonetheless, residual impacts to key benthic receptors are assessed as low:

• Excavating the nearshore approach trench and tunnel exit pit will lead to the loss of benthic habitat of different types and potentially generate suspended solids. Benthic habitats and their associated biota will experience a \textit{Low} significance impact, as a result of their regenerative ability and the limited extent of the impacts; and

• Pipe-laying (and the associated anchor footprint of the pipe-laying vessel) will have a \textit{Low} significance impact on soft substrate benthic habitats. No highly sensitive habitats exist along the pipeline alignment seaward of the tunnel exit.

Similarly, trench backfill, post-lay trenching and seabed intervention will have a \textit{Low} significance impact on soft substrate.

Because underwater noise is above background levels, it is considered a low magnitude (as opposed to negligible) impact. The impact to highly sensitive cetaceans from underwater noise has therefore been assessed as of \textit{Moderate} significance before mitigation, based on strict application of the significance matrix (Table 12.33). Because noise cannot be attenuated to negligible levels, the residual impact on cetaceans, after mitigation is still of \textit{Moderate} significance according to the matrix. However, this is not compatible with the definition of "moderate impacts" in Table 12.34, i.e. "result in lasting changes to baseline conditions, which may cause hardship to or degradation of the resource / receptor, although the overall function and value of the resource / receptor is not disrupted." As previously described, modelling of the acoustic impact of the construction spread has shown that sound is unlikely to cause mortality or injury to marine mammals and likely to only affect a group of localised individuals over a short time without affecting the overall population. This degree of impact is consistent with the definition of \textit{Low} significance because, though changes are detectable, they are very short term (no more than a few days duration) and "not expected to cause hardship, degradation, or impair the function and value of the resource / receptor." It is therefore considered appropriate to rank the significance of the impact as \textit{Low}.

A summary of the potentially significant impacts (i.e. those other than \textit{Low} or \textit{Not Significant}), showing receptor sensitivity, impact magnitude, proposed mitigation and residual impact significance is given in Table 12.38.

12.5.3  **Assessment of Impacts: Commissioning and Operational Phase**

12.5.3.1  **Introduction**

Because the scope of activities associated with the operational and commissioning impacts is small in comparison with the Construction and Pre-Commissioning Phase, the number of receptors is limited to those that might be affected by the continued presence of the Pipeline on the seabed or be disturbed by inspection and maintenance activities. Essentially this comprises the seafloor communities in deeper water where the pipe will not be trenched and the fish associated with these benthic communities, as well as seabirds and marine mammals.

Inspection activities may generate small amounts of ship wastes as described in Section 12.5.2, though to a lesser degree. All vessel discharges and wastes will be compliant with MARPOL and national regulations thus will have a negligible impact and are not considered further.

12.5.3.2  **Assessment of Potential Impacts (Pre-Mitigation)**

**Benthic Habitats**

The physical presence of the Pipeline may alter local hydrodynamics and sediment transport, with secondary impacts to benthic communities (similar in nature to those described above but much reduced in extent). This will be a highly localised effect, and will decrease over time as the seabed reaches its new equilibrium. The fact that seaweed stands are confined to the area where the Pipeline will be buried eliminates the possibility of impact to highly sensitive benthic communities.

The pipelines and associated seabed intervention will provide hard substrate in areas where such is absent and act as an artificial reef that will be colonised by sessile biota. This may therefore increase the habitat and species diversity locally and have a limited positive effect.

It is thus considered that the effects of the presence of the operational Pipeline on benthic communities is long term and of low magnitude and **Low** significance prior to mitigation and may provide localised benefits.

**Fish**

The pipelines and associated seabed intervention will provide hard substrate in areas where such habitats are absent and so will act as an artificial reef and/or fish aggregation device. This is partially due to the shelter provided by the pipe structures themselves and partially due to the colonisation of the concrete coated pipe and seabed intervention by epifauna on which fish feed. This phenomenon has been observed on numerous pipelines and is exploited by fishermen in some parts of the world (e.g. the North Sea).

However, because most of the Pipeline will be in areas where fish do not occur, the effects of the presence of the operational Pipeline on fish will be long term and of negligible magnitude and **Low** significance prior to mitigation.
Seabirds

Pipeline inspection and maintenance will involve some vessel movements. The limited frequency and extent of such activities means that any interaction with seabirds will be minimal. This therefore considered a negligible magnitude impact of Low significance at worst prior to mitigation.

Marine Mammals

As with seabirds, vessel movements (including vessel noise) associated with Pipeline inspection and maintenance is a low magnitude impact of Moderate significance prior to mitigation.

Alien Species

As with construction, vessel movements during the Operational Phase have the potential to inadvertently introduce non-native species, though this is exceptionally unlikely given the limited duration and frequency of vessel deployment for inspection and maintenance. Despite its low probability of occurrence, the possibility of population or community wide effects makes this a High significance impact prior to mitigation, for all marine ecological receptors.

12.5.3.3 Mitigation and Monitoring

Given the limited scope of operational impacts of the Pipeline compared with those identified in association with the Construction and Pre-Commissioning Phase, mitigation is limited to a subset of the measures described above for management for vessel movements and operations etc. during inspection and maintenance, specifically:

- A qualified MMO will be present to assist in managing mammal interactions;
- Vessel movements during inspection and maintenance will be kept to a practical minimum to minimise disturbance to marine mammals and seabirds;
- Vessels will not approach animals unless it is not possible to avoid doing so;
- Vessel wastes will be managed as per the construction phase, compliant with MARPOL, Bucharest Convention and National regulations (see Section 12.5.2.3); and
- Similar vessel management and controls will apply to inspection and maintenance boats as for construction vessels, to minimise the risk of accidentally introducing non-native organisms.

Operational monitoring will be integrated into the Project’s Overarching Environmental and Social Monitoring Programme, as developed for the Russian national EIA previously outlined and detailed in the Project’s ESMP.

12.5.3.4 Residual Impacts: Commissioning and Operational Phase

The limited scope of operational and commissioning impacts compared to those identified for the Construction and Pre-Commissioning Phase means that no significant residual impacts are expected following the implementation of the above mitigation measures. The potential operational effects, their mitigation and residual impacts are summarised in Table 12.39.

12.5.4 Assessment of Impacts: Decommissioning Phase

12.5.4.1 Introduction

Decommissioning of the South Stream Pipeline will be carried out according to prevailing international and national legislation and regulations and best practices regarding environmental and other potential impacts.

A review, and relevant studies if necessary, will be undertaken during the Operational Phase to confirm that the planned decommissioning activities utilise GIIP and are the most appropriate to the prevailing circumstances and future land use. The review will outline management controls and demonstrate that the decommissioning activities will not cause unacceptable environmental and social impacts. The decommissioning activities will also require all relevant approvals and authorisations from the Russian Government departments responsible at the time.

It must be therefore stressed that the assessment of decommissioning impacts set out below is provisional, based on current practices and technologies. It is not intended to be definitive, but may serve as a high level comparison between broad strategies.

Essentially two options are available; namely in situ decommissioning or pipe removal.

- In situ decommissioning involves cleaning the Pipeline and filling it with seawater. The receptors that might be impacted are thus the same as those for the operational Pipeline, with the additional possibility that some fish or swimming invertebrates may be entrained during pipeline flooding; and
- Removal of the Pipeline is essentially a similar operation to pipe-laying, but in reverse. The receptors and degree of impact will thus be similar to those identified for the construction phase.

The generic significant impacts that may be associated with decommissioning are summarised below, though pending the Project’s decommissioning studies at the appropriate time, these are not fully assessed here.

12.5.4.2 Assessment of Potential Impacts (Pre-Mitigation)

Plankton

As with construction, it is highly unlikely that either decommissioning option will result in any appreciable effects on plankton or planktonic systems.

Benthic Habitats and Organisms

If the Pipeline is to be decommissioned and abandoned in situ, the discharge of cleaning water may result in local deterioration of water quality, alteration of hydrodynamic and resultant seabed disturbance potentially affecting the benthic community on a localised scale. Effects will be localised and no appreciable changes will accrue to ecological features.
Benthos will be disturbed by rock removal and excavation of the Pipeline in the nearshore and in some limited parts of the offshore area where seabed intervention has been required. In addition, resettling of suspended solids may cause some smothering resulting in direct mortality as well as impairing the ability of some organisms to feed, respire and photosynthesize.

Importantly, less resilient seaweed communities are predominantly confined to the area landward of the tunnel exit and may experience less severe impacts. Different areas of seabed will be impacted to differing degrees, but as with Pipeline installation it is highly unlikely that the region’s overall integrity will be impacted.

**Fish**

The impact to fish of pipeline recovery will be variable. Small, benthic dwelling species are likely to be more severely impacted through habitat loss, loss of food resource and smothering. Resuspension of sediments may cause damage to gills in some cases.

Noise and vibration will be generated during excavation and pipe lifting. Sound levels are likely to be similar to those generated by trenching and pipe-laying (see Section 12.5.2), thus are unlikely to cause mortality or injury to fish.

**Seabirds**

Seabirds may be disturbed and displaced from feeding areas by vessels, or if pipe needs to be removed from the shore crossing tunnel. Additional indirect, short term effects may occur to a localised part of the population as a result of displacement or loss of prey in the nearshore area.

**Marine Mammals**

Vessel movements during pipe recovery may disturb marine mammals. Collisions may also occur. However, as discussed on Section 12.5.2, these animals are generally able to avoid areas of disturbance and only a few individuals are likely to be affected.

Noise and vibration generated during excavation and pipe lifting will have similar impacts to those generated by trenching and pipe-laying (see Section 12.5.2).

### 12.5.4.3 Mitigation and Monitoring

In the event that the Pipeline is to be abandoned in situ, the following mitigation will reduce adverse impacts to marine ecological receptors. It must be stressed that this is an indicative list of the types of mitigation that may be applied. Evolving technology and regulatory frameworks will mean that the actual management methods may differ by the time the Pipeline needs to be decommissioned:

- Non-toxic chemical additives to be used for pipe cleaning;
- The discharge of cleaning waters will all be optimised to achieve maximum dispersion and minimal seabed disturbance;
- Seawater intakes during pipe flooding will be designed to minimise impingement and entrainment of marine organisms by appropriate positioning and minimising the velocity of the intake, as well as to minimise seabed disturbance; and
• If the pipe is to be flooded, intake screens will be used to prevent entrainment of fish and large invertebrates and minimise injury and/or mortality.

If the Pipeline is to be removed, the mitigation required will be similar in essence to that for pipe-laying described and seabed interventions, in summary:

• Where excavation of the pipe is required, the choice of equipment will be made to minimise sediment re-suspension (within engineering constraints). Additional turbidity reduction measures may also be used, particularly in more sensitive areas;

• Dynamically positioned (DP) vessels will disturb the seabed less than anchored barges, (though there is likely to be a trade off with respect to noise, as DP vessels are often noisier);

• All vessel discharges, wastes and ballast will reflect GIIP and be compliant with any international and national regulations pertaining at the time; and

• Monitoring will be required whichever decommissioning option is selected. In the event that the Pipeline is removed, a comprehensive suite of monitoring comprising decommissioning and post decommissioning monitoring of water, sediments, plankton, benthos, fish, birds and mammals will be required consistent with that developed for the Construction and Pre-Commissioning Phase.

A detailed scope for appropriate monitoring will be developed at the time of decommissioning, taking into account prevailing environmental conditions, GIIP and available technology.

12.6 Unplanned Events

The potential impacts associated with unplanned events are discussed in Chapter 19 Unplanned Events.

During the Construction and Pre-Commissioning Phase of the Project, unplanned events in the marine environment may occur as a result of maritime accidents involving one of more vessels. The resultant effects of these unplanned events will be limited to accidental pollution incidents involving fuel and oils which could result in a significant adverse ecological impact. The design controls that will be in place to reduce the risk of occurrence of the above potential events, as well as the mitigation measures that will be enforced to minimise the consequences associated with the events, are discussed in Chapter 19 Unplanned Events.

Vessel operations also have the potential to inadvertently introduce invasive alien species, either in ballast water, on the biofilm inside ballast tanks or carried as fouling organisms on the hull.

During the Operational Phase of the Project unplanned events at sea may occur as a result of accidental leakages of natural gas from the subsea Pipeline. This could be incurred by third-party vessel interaction with the Pipeline by events including sinking, grounding and anchor or dropped object (such as a container) damage to the Pipeline.
12.7 **Cumulative Impacts**

The cumulative impacts associated with the Project relating to marine ecology are assessed in Chapter 20 Cumulative Impact Assessment.

12.8 **Conclusions**

The Construction and Pre-Commissioning Phase of the Project has the greatest potential to impact marine ecological receptors, particularly benthic communities. Many impacts are reduced to Low or Not Significant through project design and mitigation measures, principally by careful routing and choice of dredging and trenching technology that minimises impact to the seabed and sensitive benthic communities.

Operational and commissioning impacts relate to the presence of the Pipeline on the seabed directly and indirectly affecting habitat structure, as well as disturbance due to inspection and maintenance activities. These impacts are all potentially moderate at most, prior to mitigation. Operational impacts are largely mitigated through ensuring the stability of the pipe on the seabed and through control of vessel activities during inspection and maintenance. These mitigation measures will reduce operational and commissioning impacts to marine ecological receptors to Low significance.

While it is not possible to fully assess decommissioning impacts at this stage, it is possible to contrast two broad strategies; namely in situ abandonment and pipe recovery. The former generates impacts broadly similar to those of the Pipeline Operational Phase, while the latter generates impacts broadly similar to the Construction and Pre-Commissioning Phase, and are thus amenable to similar mitigation strategies.

The key residual impacts to marine ecological receptors are thus as follows:

- The nearshore approach trench will lead to the loss of benthic habitat of all types and generate plumes of suspended solids. Benthic habitats and their associated biota will experience a Low to Moderate significance impact, as a result of their regenerative ability and the limited extent of the impacts;
- Pipe-laying (and the associated anchor footprint of the pipe-laying vessel) will have a Low to Moderate significance impact on benthic habitats;
- Trench backfill, post-lay trenching and seabed intervention will similarly have Low to Moderate significance impact on both shallow water and deep water seabed habitats; and
- Acoustic impacts are likely to be of Low significance to fish and cetaceans.

13 **Landscape and Visual**

### 13.1 Introduction

This chapter presents the process and findings of the Landscape and Visual Impact Assessment (LVIA) for the South Stream Offshore Pipeline – Russian Sector (the Project).

There are two elements to the LVIA; first, the actual physical changes to the landscape (impacts on landscape character and quality) and second, the perceived changes and the impacts that those have on a visual receptor (impacts on views and visual amenity). For the purpose of the ESIA process, a clear distinction is drawn between landscape and visual impacts as follows:

- **Landscape Impacts**: These relate to the degree of change to physical characteristics or components of the landscape, which together form the character of that landscape, e.g. landform, vegetation and buildings; and
- **Visual Impacts**: These relate to changes to elements of existing views and the amenity of visual receptors, e.g. residents of dwellings, users of public footpaths or motorists passing through the area.

An understanding of the nature of any project is vital to the LVIA process, including all Project activities that could affect landscape and visual amenity during a project's lifecycle, from construction through to decommissioning.

The baseline information, obtained through comprehensive desk and field studies, includes description, classification and analysis of the landscape and visual resource. Due to the nature of the Project and the fact that it entails operations on both land and sea, an assessment of the seascape resource is included in addition to the landscape resource.

Whereas this chapter assesses the character and visual amenity of the landscape and seascape in the vicinity of the Project, details of their ecological make-up are assessed in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology. The perceptions of people living and working locally, as well as visiting the area, are fundamental to the assessment and, as visual receptors, are identified in this chapter; details of the communities and population are provided in Chapter 14 Socio-Economics. The combination of human activity and natural processes are fundamental to the evolution of landscape, and heritage aspects are covered in Chapter 16 Cultural Heritage.

The assessment process establishes the sensitivity to change of each receptor, identifies likely landscape and visual impacts and determines the magnitude and significance of those impacts. Mitigation measures designed to avoid, reduce or remedy adverse impacts, are identified and their likely effectiveness also assessed.

### 13.2 Scoping

The anticipated scope of the LVIA was set out in the ‘South Stream Offshore Pipeline – Russian Sector: Scoping Report’. 
The scope of the LVIA for the Project was defined through a scoping process which identified receptors and potentially significant impacts related to the Project. Baseline information which informed the scoping process largely drew on satellite imagery, topographical data and photographic records. Key steps in the scoping process for landscape and visual assessment comprised the following:

- A review of relevant national and international legislative requirements and lender requirements was undertaken to ensure legislative and policy compliance;
- The Project description was reviewed to identify activities with the potential to significantly affect receptors;
- Receptors within the Project Area of Influence were identified for landscape character and visual amenity. This was done through a process of secondary data review (Section 13.4.2), previous studies undertaken for the South Stream Offshore Pipeline and professional expertise; and
- Discussions were held with South Stream Transport representatives and project engineers to establish which activities were expected to interact with receptors, and whether this would result in a positive or negative impact.

The assessment has been informed through this process of impact and receptor identification.

The consultation undertaken as part of the ESIA process is provided at Chapter 6 Stakeholder Engagement. Comments were made during the consultation process by local communities about potential significant adverse impacts on landscape and visual amenity of an area that attracts large numbers of tourists and visitors (written comments from local communities 20th November 2012 to 31st January 2013). Several of these comments relate to the key objective of the LVIA which is to identify and assess the significance of potential adverse impacts on the landscape and visual amenity. Appropriate management and mitigation measures will then be identified and implemented to address these impacts on potentially sensitive visual receptors. Consultation with stakeholders is recognised as an effective way to better understand the receptor sensitivity and more accurately use professional judgement to assess the significance of residual impacts.

### 13.3 Spatial and Temporal Boundaries

The Project Area is described within Chapter 5 Project Description, a brief description of the elements pertinent to potential landscape and visual impacts are summarised below. The Project Area is subdivided into three sections of the Pipeline: the landfall, nearshore and offshore. It also includes proposed transport access routes from the existing M25 highway at Rassvet; these include bypass roads around Gai Kodzor and Varvarovka, and then further access roads to the Project. Access roads are proposed to be used for deliveries and worker transportation associated with the Project. Some of these access roads are temporary and are only required for the Construction and Pre-Commissioning Phase. Details of the access roads and associated construction are provided within Chapter 5 Project Description.

For the purpose of this LVIA the following areas have also been defined and are referred to within this chapter:
Study Area

The landscape Study Area has been defined to include the landfall, the nearshore and offshore sections of the Project Area, and the access roads leading from the Project to the M25 junction at Rassvet. This has been selected to encompass the area where there is potential for impacts on landscape character and/or visual amenity. It includes areas where views of the Construction and Pre-Commissioning and Operational Phases of the Project could potentially be perceived, including areas with views of vehicles on land (including on the access roads) and the movement of construction vessels up to 10 km from the shore (including potential sea delivery routes to Novorossyisk Port). A 10 km limit has been chosen as that is considered to be the furthest distance that views of vessels could potentially be perceived, based upon their size and an assumed level of visual acuity.

The location of the Study Area is shown in its regional context in Figure 13.1, in particular with reference to two key geographical features: the Azov-Kuban lowland and the Greater Caucasus Main Range Mountains. The Study Area itself is shown in greater detail on Figure 13.2.

Survey Area

Within the Study Area, a smaller area has been defined where it is considered, based on previous experience of similar development projects, that there is greatest potential for significant direct or indirect impacts on landscape character and visual amenity arising from the Construction and Pre-Commissioning and Operational Phases. This area extends between the proposed microtunnel entry shafts and the proposed connection point with the upstream United Gas Supply (UGS) System. The determining factor in the extent of this area is the topography and vegetation in the vicinity, which influences intervisibility and encloses the proposed development. This was verified by a combination of desktop study, Zone of Theoretical Visibility (ZTV) analysis and field reconnaissance. The boundary for this Survey Area is therefore limited to 4 km radii from both the microtunnel entry shafts and landfall facilities (as illustrated on Figure 13.3).

The Survey Area includes the following:

- Areas of land and sea from which the landfall section (between the proposed microtunnel entry points and the proposed connection with the Russian gas network) could potentially be visible based on landform only (i.e. without taking account of woodland or built-up areas); and
- Areas of land and sea from which the landfall facilities (including above ground structures and the stack) could potentially be visible based on landform only (i.e. without taking account of woodland or built-up areas).

---

1 Intervisibility is defined by the state of being mutually visible

2 ZTV: The Zone of Theoretical Visibility represents the geographical area (zone) within which the landscape and/or seascape where the Project is theoretically visible, based upon a ‘bare-earth’ digital model of the Study Area.
Potential indirect impacts are also considered in this assessment, such as impacts of construction vehicles using the access roads on settlements outside of the Survey Area.

**Zone of Theoretical Visibility**

The Zone of Theoretical Visibility drawings (ZTVs), referred to above, were generated using computer modelling using ESRI ArcGIS software with a Spatial Analyst extension (refer to Section 13.4.2 for further detail of the data used). These images depict the area within which the Project would theoretically be visible and as such has potential to influence or impact on visual amenity. However, it should be noted that the ZTV is calculated using a *bare earth model*, i.e. one which does not reflect the screening effect of intervening structures such as buildings, or vegetation. As such, it is subject to further on-site verifications to verify actual visibility on the ground.

The ZTV is used primarily for identifying the location of potential visual receptor groups which are then subject to an on-site verification process to determine the context and extent of actual views, and potential views, of the Project.

Further details of the modelling undertaken to determine the ZTVs of the offshore and nearshore sections, the landfall facilities, and the landfall section are provided in Section 13.5.4.1.

13.4 Baseline Data

13.4.1 Methodology and Data

A desk study of secondary data available including reports on designated Protected Areas in the vicinity of the Project, satellite imagery, topography, site layouts and photographs was initially undertaken to inform the assessment of landscape and visual amenity. In particular, existing topographic data was used as the basis for a Geographical Imaging Systems (GIS) terrain model; known elevations of the various parts of the Project were then overlaid onto this to determine the ZTVs associated with the Project and hence, to estimate the locations from which elements of it would be visible. Following this, a gap analysis was undertaken to inform the need for primary data sources to fill the data gaps. Field work was then undertaken to obtain primary data relating to landscape character and visual amenity. The secondary and primary data used to inform this LVIA is detailed in the following sections.

13.4.2 Secondary Data

The following sources of secondary data have been reviewed as part of this assessment:

- ESRI High resolution satellite imagery;
- ASTER 30 m resolution Digital Terrain Model;
- ASTER 10 m resolution Digital Terrain Model; and
- Photographs.

13.4.3 Data Gaps

Following the collation of the above data, the following gaps were identified:

- Condition of existing landscape;
- Classification of landscape and seascape character at a regional and local scale; and
- Condition of existing views experienced by sensitive visual receptors.

13.4.4 Primary Data and Baseline Surveys

Visual receptors are specific individuals or groups who are expected to have views of the Project and therefore may experience effects on their amenity. In order to identify visual receptors, a combination of computer-generated ZTV models and assessment work in the field is required.

Landscape and visual surveys of various parts of the Survey Area (Figure 13.3) were undertaken in June and December 2012, April and August 2013, and April 2014. The purpose of the surveys was to understand the existing landscape character, to verify the ZTV and identify potential visual receptors, and to confirm that the available secondary data was representative of the Survey Area. A photographic record of landscape types and views from publicly accessible vantage points has been collected during the course of the surveys including recording the
Geographically Positioning System (GPS) location data of individual images. The work carried out during each visit is summarised in Table 13.1.

**Table 13.1 Site Survey Summary**

**13.4.5 Data Assumptions and Limitations**

It has not been possible to ascertain the full extent of recreational paths or tracks within the Survey Area, although it is acknowledged that during summer months, recreational activities, such as horse riding may take place. However, the Study Area has widespread forest cover with pockets of open land utilised for agriculture and viticulture. Since views within the forested areas would naturally be screened by the trees it is assumed that the receptors would be confined to locations within the open agricultural landscape, on the coastal paths and on local beaches etc.

Assumptions on the extent of some views have been based upon satellite imagery, topographical data, desktop analysis and professional judgement alone, due to inaccessibility. This has been used to determine the likely views towards the nearshore and offshore sections of the Project and effects on landscape character for locations which are not publicly accessible, such as private residences in Sukko, holiday complexes and private beaches at Shingari and Don, and the ‘Utrish’ state nature reserve.
Assumptions on the proposed Russkaya compressor station (currently under construction) have been made for inclusion in the cumulative assessment in Chapter 20 Cumulative Impact Assessment. In that chapter it is noted that the scale of the Russkaya compressor station is far greater than that of the Project, it has been assumed that the proposals for the Russkaya compressor station will be similar in character and style, including similar appearance of Right of Way (RoW), infrastructure and fencing, etc. It is also assumed that a landscape restoration plan, including the management requirements, and all other mitigation would be applied similarly to those proposed for the Project; effectiveness of these measures in mitigating adverse impacts from the Russkaya compressor station would be reduced due to the larger scale of that development in comparison to the Project.

13.5 Baseline Characteristics

13.5.1 Context

This section presents a description of the existing landscape and visual characteristics within the Study Area (Figure 13.2), with particular emphasis on the landscape character and visual amenity of the Survey Area (Figure 13.3).

The Study Area contains two key landscapes, the foothills of the Caucasus mountain range (to the south) and Abov-Kuban (lowland to the north and east), and the Black Sea makes up the western area.

Within the Study Area is the city of Anapa, a popular holiday destination in Russia noted for its beaches, warm climate and the presence of sites of historical and natural interest. Of particular note is the state nature reserve “Utrish”, protected for its rare flora (refer to Section 13.5.2.5 for more detail). The land throughout the Study Area is mostly used for viticulture with the majority of grapes used for local wine production. Tourism activities are associated with Anapa, and the surroundings within the Study Area are also well known for its onshore and offshore cultural heritage (refer to Chapter 16 Cultural Heritage for more information).

The Study Area (Figure 13.2) shows the Project within the surrounding landscape context, including access roads. Figure 13.2 also identifies the two small settlements located along these roads which may experience potential impacts.

The key focus of this LVIA is the Survey Area; this encompasses a 4 km radius around the area of the landfall section, and any activity in the nearshore and offshore sections including vessels on the open sea surrounding the coast. The Survey Area itself is largely dominated by agriculture but also contains small settlements and pockets of development. The Survey Area is characterised by the wooded, undulating topography in the vicinity of the landfall section, comprising the land generally defined by the Black Sea coastline to the west, Supsekh to the north and Sukko to the south, with the wide expanse of open sea extending to the west. Photographs indicating the baseline can be seen in Section 13.5.4.3, Viewpoints 1b, 2a, 5a, 6, 7 and 8.

The landfall section of the Project, which includes the proposed microtunnels, passes through a landscape of potentially sensitive character and visual amenity, comprising a pattern of woodland, fields, coastal slopes, cliffs and foreshore. It does not, however, lie within or close to
any protected landscapes, although, as noted, the state nature reserve “Utrish” lies approximately 4 km southeast of the landfall section, extending just to within the Survey Area beyond Sukko. A number of vineyards and areas of state forest are located within the Survey Area on the proposed Pipeline route.

Based on the visual quality of the woodland and agricultural landscape, the scoping exercise identified that the local landscape within the Survey Area is important for both residents and tourists who visit the region.

13.5.2 Existing Landscape and Seascape of the Survey Area

The landfall section lies in an approximately south-western direction approximately 0.5 km southeast of Varvarovka and 2.5 km northwest of Sukko. The four pipelines are proposed to be microtunnelled beneath the coastal cliffs to the Black Sea, as shown in Figure 13.3. The pipelines will be laid on the seabed in the offshore section. The Black Sea is frequently crossed with commercial shipping vessels, shipping and tourist boats. Within the Survey Area the coastline is formed largely of cliffs with a few small bays and beaches to the south.

The location of the landfall section has been driven primarily by the need to connect with the location of the proposed Russkaya compressor station and the four connecting pipelines which form part of the “Expansion of the UGS to provide gas to South Stream pipeline” that is being developed separately by Gazprom. The Project's landfall facilities would be located immediately adjacent to these four Gazprom pipelines, approximately 2.5 km west of the Russkaya compressor station.

13.5.2.1 Landscape Setting

The landscape is largely characterised by woodlands and open fields across the undulating topography of the Shingar River valley to the northwest and Sukko River valley to the south and southeast. The landscape is also defined by cliffs of the Black Sea coastline to the West (Figure 13.3).

The onshore part of the Survey Area is characterised by gently rolling hills with a combination of agricultural fields, principally viticulture, and forest sloping down towards the south and southwest. The microtunnelling section (where the Pipeline transitions from the sea onto land) runs beneath the coastal cliffs and the Shingar River.

There are only a few man-made features within the onshore part of the Survey Area; the most significant built features are the urban areas of Varvarovka and Sukko. The area is therefore considered to have a relatively high natural amenity value. However, the landfall section is fairly secluded from views from the surrounding settlements and the local limited road network, as it is intermittently screened by forest and topography. The Project's nearshore and offshore sections are, however, visible from parts of the shoreline across the open water.

Panoramic views within the lower reaches of the valleys are limited. However, areas of more open land in the upper catchments allow lines-of-sight across the valleys, chiefly from elevated locations, for example, at Southern Sukko and Eastern Varvarovka with distant hills forming the horizon to the South and East.
13.5.2.2 Topography

The Survey Area is located in foothills between the Greater Caucasus Main Range Mountains and the Azov-Kuban lowland (Figure 13.1) at an approximate elevation of 200 m. The majority of the onshore Survey Area comprises an undulating plateau extending northeast from a steep coastal slope with the shoreline of the Black Sea at its base (as shown in Figure 13.4). This topography forms valleys to the watercourses in the Survey Area include the Shingar River (1.5 to 2.5 m wide), the Sukko River and an unnamed tributary of the Sukko River (as shown in Figure 13.3).

The plateau has been eroded with gullies in places, as described in more detail in Chapter 7 Physical and Geophysical Environment. Further information on watercourses, including valley and water channel features associated with intermittent waterways that flow during periods of high rainfall, can be found in Chapter 8 Soils, Groundwater and Surface Water.

13.5.2.3 Land Use and Vegetation

Land use in the Survey Area is a combination of forest, viticulture, residential development, tourism facilities and road infrastructure. Viticultural activity consists primarily of the cultivation of grapes for wine production. There is a mix of mature and young vineyards, as well as large areas where vines have been previously planted but are currently abandoned or left as fallow fields. These fields are often divided with narrow tree belts and hedges, or edged (unfenced) by roads and unsealed tracks (refer to Chapter 14 Socio-Economics).

A broad range of naturalistic land cover is present within the Survey Area including forest, juniper woodland, meadow, tomillyar (areas of herbaceous species associated with dry, hot environments), rocky outcrops, coastal shingle and vast areas of scrub and tall shrubs known as shiblyak. Shiblyak covers the greatest of this land area. Steppe meadow consisting of grasses and herbaceous species is also a prevalent and characteristic land cover, typically resulting from derelict agricultural land. Agriculture is widespread and dominated by vineyards. As such, the linear parallel rows of grapevines are a key component of the landscape character. Juniper woodland and scrub occurs on the rocky south-western exposed slope along the coastline. A more detailed description of the forest vegetation is included in Chapter 11 Terrestrial Ecology.

The distribution of land use is mainly agricultural fields located around the outskirts of the residential developments i.e. in greater concentrations in the north-east and south-west of the Survey Area; and woodland further afield i.e. to the east, and centrally within the Survey Area (Figure 13.3).

The agricultural lands vary in appearance through the changing seasons, creating a green, lush and vegetated appearance during the summer and a more sparse, earthen, brown-coloured appearance during the winter, due to the extent of this land use, this has an impact on the character and visual amenity of these areas.

There are two lines of overhead power cables within the Survey Area, one of which crosses the landfall section (Figure 13.3).
13.5.2.4 Settlements

The landfall section of the Project is located approximately 10 km southeast of Anapa. With the exception of Anapa, the surrounding area is largely rural and typified by small to medium-sized settlements near the landfall section, set amongst rolling hills behind the cliffs on the shore of the Black Sea. The term 'settlements' is used here to represent the geographical features and not the communities which live within them, descriptions of the communities within these settlements can be found in Chapter 14 Socio-Economics.

The two main settlements within the Survey Area are Varvarovka and Sukko. The southern edge of Supsekh also falls within the Survey Area to the north but is visually separated by the intervening topography; the small settlement of Gai Kodzor is located just outside of the Survey Area, to the northeast (Figure 13.3).

The nearest main settlement to the landfall section is Varvarovka; a town with a population of approximately 2,300, typified by its built form and infrastructure being spread along the well-treed hill which slopes through the settlement. The settlement pattern of Varvarovka is predominantly linear, formed between high undulating ridges to the east and west, low-lying to the south and elevated to the north, with the main road forming the central axis for development.

The nearest existing buildings are located approximately 800 m north of the proposed microtunnel entry points; however, “Lesnaya Polyana” - the Clearing in the Woods - a proposed extension to Varvarovka, which is located approximately 500 m to the north-west, is currently under construction although no structures have yet been built on the property. In the north-eastern area of Varvarovka there are several elevated modern properties with long distance panoramic views across the adjoining landscape to the south, east and west. To the east of Varvarovka is the location of the proposed ‘Chateau’ residential development. Varvarovka consists of two main streets (one sealed) connected by a number of dirt roads, most houses being single- or two-storey detached structures arranged along the hill which slopes through the town. Varvarovka has a number of amenities such as a nursery and a general school, a community centre and a sports centre along with a few small shops. The Kavkaz Winery, a grape producer and wine maker, is located on the main sealed road. Varvarovka is also the headquarters of Briz, one of two small commercial fishing organisations in the Anapa area. There is a Russian Orthodox and Armenian cemetery located on the edge of the settlement (Figure 13.3), from which there are wide spreading panoramic long distance views which include parts of the landfall section.
Residential properties on the northern outskirts of the town of Sukko are located 2 km southeast of the landfall section, with the intervening land consisting of dense woodland. Sukko is a town with a population of approximately 1,700 organised along a single, long road that runs through the middle of the town with the western end leading to the beach, which is the main, easily accessible public beach between the town of Anapa and the state nature reserve “Utrish”. The development is also broadly linear restrained by the Sukko River to the north and therefore lies on the southern valley side. Sukko has a kindergarten, a sports centre and a health-care facility, as well as many restaurants, shops and kiosks catering for visiting tourists. Many of the buildings are four to five storeys high and appear to be hotels. Most other buildings are one to two storey detached houses, similar to those found in Varvarovka. Next to the public beach, Sukko also has a children’s holiday camp, called Smena or ‘Time Off’, which is well known in the area.

13.5.2.5 Protected Areas

An overview of policy relevant to the Project is provided in Chapter 2 Policy, Regulatory and Administrative Framework. The following Krasnodar Krai legislation is, however, relevant to landscape aspects of the Project. These allocations are not statutory designations and furthermore, are not based on the protection of landscape character or visual amenity specifically.

Utrish Nature Reserve

Federal law ‘On Specially Protected Natural Areas’ 14.03.1995, No. 33-FZ establishes a system of specially protected natural areas, specifies conditions of their use and protection of natural resources (Figure 13.2). The protected area ‘Utrish’ is located approximately 4 km southeast of the landfall section of the Project. The establishment of state nature reserve “Utrish” is required for the preservation of ancient Mediterranean ecosystems, their biota and landscapes. The establishment of the nature reserve is considered to be the only appropriate measure to stop the destruction of the Mediterranean landscapes, in particular flora and fauna, resulting from the haphazard development of recreational facilities. These woodland areas provide functions including habitat formation, water conservation, soil protection and erosion control value (Ref. 13.1). Whilst this protection is predominantly ecological based, the reserve and the associated flora and fauna contribute to the landscape character of the Survey Area and it is therefore considered further in this assessment.

Sanitary Protection Area of Anapa

The Resort Town of Anapa (see Figure 13.2) was assigned the status of a federal resort by President Decree No. 1954 dated 22 September 1994. It was given this status due to its recreational value as a ‘health improving’ (spa) resort area.

Although the Project does not fall within any part of the Sanitary Protection Area, the Survey Area does contain the sanitary protection area of Anapa exclusion zones, limitation zones and monitored zones (refer to Figure 13.3 for locations, and Chapter 2 Policy Regulatory and Administrative Framework for further detail on these zones), the quality of the environment within this area attracts high visitor numbers and as such it is considered sensitive to changes in
views and landscape character. Due to the relative close proximity to the Project and potential for views of vessels along sea delivery routes, it is considered relevant to this chapter.

### 13.5.2.6 Tourism

Anapa is an area recognised for its importance for tourism (it was formalised by a presidential decree in 1994 and Russian Government Executive Order in 1996, No. 591-p.) the main resort is located 10 km to the north of the microtunnel entry points.

Tourism is also well established in Sukko and marine activities include recreational scuba diving, yachting, paragliding, recreational fishing, ferries and beach activities.

Shingari holiday complex and Don holiday complex are located approximately 1.3 km south of the microtunnel entry points (the closest element of the Project to these tourist areas), built on the cliff-top with a private beach accessible by stairs from the former, and by a path from the latter. For further information about these complexes, refer to Chapter 14 Socio-Economics.

### 13.5.2.7 Roads and Paths

The main Varvarovka-Sukko road and the coastal path along the cliff top, running approximately parallel with the coast in a north to south alignment, both cross the landfall section (Figure 13.3). There are numerous other unsealed (dirt) tracks along field boundaries associated with agricultural access.

The settlements of Rassvet, Gai Kodzor and Varvarovka are located in close proximity to the proposed access roads between the M25 and the landfall section (Figure 13.2). These settlements are connected by sealed (hard surfaced) roads. Within the Survey Area, the majority of other roads and access points are unsealed (dirt tracks). Within this Chapter, consideration is given to Project-related traffic from the M25 junction at Rassvet and along the access routes towards the construction sites. Where Project-related traffic uses the major existing highway network (from the M25 junction and beyond) it is not considered relevant to potential landscape character and visual amenity impacts within this assessment.

### 13.5.2.8 Offshore and Nearshore Activities

Passengers and crew on commercial shipping and fishing boats are the closest receptors in Russian coastal waters to the offshore and nearshore areas.

Tourism is well established in Anapa and Sukko where water-based activities, principally during summer months, include recreational scuba diving, yachting, water-skiing and passenger / tourist transport (including ferries) close to the shorelines of these towns. Beach users and recreational fishing would also gain views of the offshore and nearshore areas.

### 13.5.3 Landscape and Seascape Character

Landscape and seascape character assessments are used to assist in understanding and articulating the character of the landscape. It helps to identify the features that give a locality its sense of place and elements that contribute to the landscapes distinctiveness, to make it different from neighbouring areas.
Landscape is defined as an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors (Ref. 13.2). Seascape is used to indicate landscapes with views of the coast or seas, and coasts and the adjacent marine environment.

Landslides and seascapes are experienced as a combination of elements (physical features and perceptual qualities) and which are ascribed value by human receptors. Typical landscape components include landform, land cover and land use. The aesthetic and perceptual aspects of the landscape and seascape include such aspects as scale, openness / enclosure, form, pattern, unity, colour, movement etc.

Landscape and seascape resources in the Survey Area have been classified into landscape character areas (LCA) and seascape character areas (SCA) and are categorised according to sensitivity, determined essentially by the quality and value of the LCA / SCA, and its ability to accommodate change.

The majority of the onshore part of the Survey Area is covered with mixed native forest and interspersed with varying amounts of open ground. No published assessments have been identified within the secondary data which characterise the landscapes or seascapes within the entire Study Area, as such, and therefore for the purpose of this assessment, the following LCA and SCA have been defined in line with the Guidance on Landscape Character Assessment (Ref. 13.3), namely:

- Undulating Plateau LCA; and
- Black Sea Coastal SCA.

These are shown on Figure 13.5. Also shown on Figure 13.5 are the urban areas of Supsekh, Varvarovka and Sukko (photograph viewpoint 8 in Section 13.5.4.3), which are separate from their surrounding LCA, exhibiting different characteristics, development, resources and setting. They are too extensive to be accommodated as features within that LCA and are therefore excluded from the character assessment. Both the LCA and the SCA comprise constituent character types, as described below. These correspond with the habitat types described in Chapter 11 Terrestrial Ecology.

**13.5.3.1 Undulating Plateau LCA**

The Undulating Plateau LCA, being the rolling, extensively wooded, rural landscape extending inland away from the coast, comprises three main character types (photograph viewpoint 6 and as shown in Chapter 11 Terrestrial Ecology), as follows:

- **Forest** - typically characteristic of Krasnodar Krai, undersized, arid woodland known as shiblyak, being diverse in structure and floristically rich;
- **Wooded valleys** - linear relief depressions created by the watercourses and intermittent waterways, chiefly wooded (mesophilic forest) but interspersed with open areas (mesophilic meadow); and
- **Cultivated land** - open vineyards, orchards and meadows (steppefied secondary meadows); some herbaceous vegetation typical of colonised disturbed ground (Photograph viewpoints 2a, 4, 5b and 7 in Section 13.5.4.3).
13.5.3.2 Black Sea Coastal SCA

The Black Sea Coastal SCA, being the open sea and the line of landscape along the Black Sea coast made up of a combination of characteristically coastal geomorphology and vegetation, typically shoreline and cliffs, comprises three main character types, (refer to photograph viewpoints 1c and 2b in Section 13.5.4.3 and in Chapter 11 Terrestrial Ecology), as follows:

- **Coastal slope** - steep earth banks with primarily juniper woodland and some scrub (tomillyar), steepening at several points to become rocky outcrops and high coastal cliffs. The slope is interrupted in places where watercourses discharge into the sea, for example the Sukko River. Elevated views out over the sea are a key feature contributing to the character of this type (photograph viewpoints 1a-c and 2b in Section 13.5.4.3);

- **Shoreline** - gravel beach and rocky outcrops along the seashore (photograph viewpoint 1c in Section 13.5.4.3); and

- **Open sea** - extending beyond the Survey Area to the horizon. The open sea comprises the open water beyond the shoreline with its expansive skies and light conditions constantly changing with the season, time of day and weather. The water can be flat calm on still days and constantly moving on windy days, with the sound and motion of waves greatly adding to its drama. The sea is crisscrossed by shipping lanes (refer to Figure 13.1), so at times vessels form temporary features within the otherwise empty seascape and during the summer, pleasure craft are present.

13.5.4 Visual Amenity

Existing views within the Survey Area are comprised mainly of open gently undulating landscapes, with panoramic views across the woodland canopies and fields, and vast open flat panoramic views of the Black Sea. The sequential views, such as those experienced by road users, vary from open to restricted views caused by the intervening hills and woodlands. Within urban locations views are more restricted by buildings and only elevated residences gain long distance views. Key visual elements are formed of the brightly coloured built form within the settlements, the seasonal bare earth on agricultural fields, and the elevated extent of the northern ridge beyond Varvarovka and along the North-Western coast.

13.5.4.1 Zone of Theoretical Visibility

Visual receptors have been identified through a combination of computer-generated ZTV models and assessment work in the field. Individual receptors within the ZTV are categorised into receptor groups and assigned sensitivity, relating primarily to the receptors' activities and value of existing view.

A series of ZTVs have been defined to demonstrate a range of scenarios, as illustrated in the following figures:

- Figure 13.6 Offshore Construction - areas on land where offshore Pipeline construction work could theoretically be visible (generated using data points along the offshore Pipeline route at sea level);
• Figure 13.7 Landfall Section – areas on land and sea where the landfall section could theoretically be visible (generated using data points along the onshore Pipeline route at ground level); and

• Figure 13.8 Landfall Facilities – areas on land where the landfall facilities could theoretically be visible (generated using a 30 m high data point at the location of the proposed vent stack to provide a worse-case scenario; however a height of 21 m has now been confirmed for the vent stack – refer to Chapter 5 Project Description – and would produce a slightly reduced ZTV).

On-site field reconnaissance survey work undertaken to validate the ZTVs has identified that, because the landfall section is in a dip enclosed by woodland, it is substantially screened from dwellings within the Survey Area, including most parts of Varvarovka and Sukko. However, the landfall section is partially visible from upper storeys of some properties in Sukko, notably on the north-facing slope on the south-eastern side of the town, and from “Lesnaya Polyana”, the extension of Varvarovka currently under construction.

For the most part, residents would be unable to see any of the proposed landfall facilities, as potential views are screened by the surrounding topography and woodland.

The landfall section is visible from the Russian Orthodox and Armenian cemetery on the eastern edge of Varvarovka and from the coastal path which crosses the landfall section. The number of users is likely to vary depending on weather conditions and time of year.

There are also views towards the landfall section from the Varvarovka-Sukko road, which crosses above the microtunnels in the landfall section, and depending on the height of the proposed facilities at the microtunnel entry points, they would be likely to be visible from the road.

Elsewhere, the proposed landfall section is only visible from the tops of the ridges in the surrounding landscape, where, with the exception of agricultural workers, no visual receptors are present because, as far as it has been possible to ascertain, there are no formal public footpaths. However, this situation is considered to be different during summer months when recreational activities, such as horse riding take place across private land and in the vicinity of the coast.

Views of the nearshore and offshore sections are possible from pleasure craft, passenger ferries and commercial vessels, as well as the coast path and much of the coastline.

This map shows the proposed connection with the Russian gas network.
The map illustrates the proposed connection with the Russian gas network, specifically highlighting the Shingari holiday complex and its proximity to Varvarovka and Sukko. The map also shows the Russian Sector of South Stream Offshore Pipeline with proposed landfall facilities, pipelInes, and the boundary of the state nature reserve "Ouresh." The map further includes the United Gas Supply System with proposed offshore pipelines and a proposed connection with the industrial gas network.
13.5.4.2 Visual Receptor Groups

Within the Survey Area, potential visual receptor groups and their distance to the Project have been identified and are listed in Table 13.2. A number of locations have been selected to illustrate typical views for the majority of the receptor groups, referred to as representative viewpoints; these locations are shown on Figure 13.9. Photographs taken from the representative viewpoints showing views for the receptor groups are shown in Section 13.5.4.3. It is noted that all of the viewpoint locations are publicly accessible, with one exception; one photograph has been taken from private property under construction - Viewpoint 8 in Sukko.

13.5.4.3 Viewpoint Photographs

Viewpoint location photographs for the majority of representative receptor groups are set out below. For scaled viewpoint photographs, refer to Appendix 13.1: Photographs. The Project phases during which Project activities or structures will be visible from these viewpoints are detailed in Table 13.8.

13.5.4.4 Access Roads

The proposed access roads used to transport materials, machinery and workforce on and off the construction sites to existing major road network are shown in Figure 13.2 and Figure 13.3. These routes are proposed mostly along existing roads and tracks, with some areas using the routes of minor, currently unsealed, roadways. The location of the access roads pass in proximity to a number of small residential areas. In these areas some residential properties gain views across these roads and to the open landscape beyond. However, the vast majority of these routes are on roads passing through the extensive agricultural land and adjacent to woodland areas where receptors are limited to agricultural and forestry workers as shown in Figure 13.9.

13.5.5 Baseline Summary

13.5.5.1 Landscape and Seascape Character

Within the Survey Area, one LCA and one SCA have been identified. The Undulating Plateau LCA comprises the rolling, extensively wooded, rural landscape extending inland away from the coast, made up of three main character types, namely forest, wooded valleys and cultivated land. The Black Sea Coastal SCA comprises the open sea and the line of characteristically coastal geomorphology and vegetation along the Black Sea coast, made up of two main character types, namely coastal slope and shoreline.

The landfall facilities are proposed across predominantly cultivated agricultural land and a small section of wooded valley within the Undulating Plateau LCA. The Eastern section of the microtunnelled pipelines is beneath the wooded sloping landscape which backs on to the coastal slopes of the Black Sea Coastal SCA. The microtunnelled pipelines emerge below sea level and therefore impacts on this character area are likely to be limited to periods during the Construction and Pre-Commissioning Phase only; this applies to the microtunnelled section of the pipelines within the LCA also.

The distinctive linear patterned vegetation and seasonally changing appearance of the agricultural fields would provide opportunity to tolerate change such as temporary removal of vegetation cover and excavation during construction, and the undulating nature of the topography provides opportunity to tolerate and conceal localised development, such as spoil storage and site plant, without degrading the overall character of the LCA. This tolerance and lack of susceptibility to change of the type proposed by the Project is important to note and is discussed further in the impact assessment section of this chapter.

13.5.5.2 Visual Amenity

Within the Survey Area, a number of receptor groups with potential to experience an impact on their visual amenity have been identified (as listed in Table 13.2). Within this list, residential receptors include people living at Sukko and Varvarovka, potential residents of “Lesnaya Polyana” the development currently under construction south of Varvarovka, and residents living close to the access roads. Recreational receptors comprise visitors to the seashore, including the public beaches at Sukko and Anapa, and the private beach at the Shingari and Don holiday complexes, walkers on the coastal path, visitors (only permitted under Government license) to
state nature reserve “Utrish” and recreational boat users. Other receptors whose visual amenity could potentially be affected are visitors to the Russian Orthodox and Armenian cemetery at Varvarovka, travellers on the Varvarovka-Sukko and Varvarovka-Gai Kodzor roads, and agricultural workers on the land.

Due to the largely rural nature of the landscape in the Survey Area the number of potential receptor groups is relatively low. Relative numbers of visual receptors is accepted to vary greatly dependent upon seasons, with tourists visiting during summer months experiencing a shorter duration of exposure to views than permanent residents. Furthermore, it is noted that the tourist receptors are likely to be experiencing views during summer months when vegetation is in leaf and more effective at filtering views.

As noted above for the baseline character summary, the undulating topography of the Survey Area provides opportunities for concealed pockets of development to be carried out without potential views being impacted. This is a benefit of the location of the Project and is discussed further in the impact assessment section of this chapter.

13.6 Impact Assessment

This section presents and discusses the impact of the Project on landscape and visual receptors (see Sections 13.5.3 and 13.5.4). The approach to the impact assessment is based on the Guidelines for Landscape and Visual Impact Assessment (Ref. 13.4) and is outlined below:

- The magnitude of potential impacts is described as high, moderate, low or negligible based on criteria shown in Table 13.3 and Table 13.5;
- The sensitivity of each landscape and visual receptor was then classified as either: high, moderate or low based on pre-defined criteria shown in Table 13.4 and Table 13.6;
- The principal sources of potential significant effects associated with the Project are then described;
- The likely pre-mitigation impact significance (High, Moderate, Low or Not Significant) are assessed, and where possible quantified;
- Mitigation measures to avoid or reduce any Moderate or High category (significant) impacts are then developed in conjunction with other elements of the design (including mitigation for other environmental disciplines);
- The residual effects of the Project (i.e. the remaining effects taking account of proposed mitigation measures) are reported;
- Cumulative impacts of the Project in relation to other developments in the proximity of the Project Area are described and assessed in Chapter 20 Cumulative Impact Assessment; and
- Further consideration is then also given with regard to unplanned events; refer to Chapter 19 Unplanned Events for further detail.

Refer to Chapter 3 Impact Assessment Methodology for details of the methodology applicable throughout this ESIA Report. This includes the matrix used for determining the level of significance. Impacts with a significance ranking of Moderate or High are considered to be
Chapter 13 Landscape and Visual

‘Significant Impacts’. Effects can result directly from the development itself or as a consequence of the development, in the form of indirect or secondary effects, such as traffic on surrounding roads. As noted in Chapter 5 Project Description, the assessment is made for three phases of the Project: Construction and Pre-Commissioning, Operational (including Commissioning) and Decommissioning; the duration of these phases is also outlined in that chapter.

13.6.1 Impact Assessment Methodology

This section discusses the methodology used to assess potential impacts associated with the Project on the existing baseline conditions described in Section 13.5.

13.6.1.1 Impact Assessment Criteria

Criteria for Landscape and Seascape Character Impacts

Impact Magnitude

Impact magnitude criteria were developed based on the recognised Good International Industry Practise (GIIP) guidance document Landscape Character Assessment Guidance for England and Scotland (Ref. 13.3). These are summarised in Table 13.3. As detailed in Chapter 3 Impact Assessment Methodology, the impact magnitude is considered to be a function of extent, duration, frequency and reversibility; where possible these aspects have been considered in the development of the LVIA criteria. The Guidelines for Landscape and Visual Impact Assessment (Ref. 13.4) also notes the criteria for impact magnitude should consider scale, extent and duration or reversibility. It is noted, however, that some of these criteria are subjective in terms of LVIA and professional judgement in assigning impact magnitude ratings in considered a key part of the LVIA process.

Table 13.3 Impact Magnitude – Landscape and Seascape Character

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Ranging from a limited change in landscape and seascape characteristics over an extensive geographical area, to an intensive or pronounced change over a more limited area. Impact is more likely to be high if change is long-term or permanent.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Moderate change in a localised area (e.g. limited woodland clearance without compromising the overall integrity of the wider woodland area). Could include high impact change of a short-term or temporary nature.</td>
</tr>
<tr>
<td>Low</td>
<td>Minor change in scale and geographical extent (e.g. loss of small areas of vegetation or indirect impact resulting from intervisibility with development in adjoining character type). Impact is more likely to be low if change is short-term or temporary.</td>
</tr>
<tr>
<td>Negligible</td>
<td>Virtually imperceptible change to the baseline context.</td>
</tr>
</tbody>
</table>
**Receptor Sensitivity**

The sensitivity of a receptor is both a reflection of how robust (resilient or vulnerable) it is to a change in baseline conditions, as well as a description of the value ascribed to the affected landscape.

The existing landscape and seascape can be assessed in terms of the number and type of discrete landscape and seascape character areas that comprise the overall setting. The criteria for evaluating sensitivity of character areas include their susceptibility to the proposed development specifically, and the value attached to the landscape in general; these are summarised in Table 13.4. These criteria have been developed based upon the recognised GIIP guidance document, Landscape Character Assessment Guidance for England and Scotland (Ref. 13.3).

**Table 13.4 Receptor Sensitivity – Landscape and Seascape Character**

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Landscape of distinctive components and characteristics, or a relatively undisturbed, pristine landscape, where changes or disruptions to the existing landscape would be noticeable and difficult to mitigate or restore; a small change is likely to be prominent or even dominant; a change to the landscape could alter the classification and integrity of the landscape character or quality and its perceived value relative to the scale and openness.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Landscape of relatively widespread, featureless, common components and characteristics, able to tolerate some changes or modifications without altering the classification of landscape character or quality. Landscape lacking in structural landform would also be considered of medium sensitivity.</td>
</tr>
<tr>
<td>Low</td>
<td>Landscape of relatively indiscernible components and characteristics, the nature of which is likely to be tolerant of substantial change, where modifications are unlikely to alter its character or quality classification. Landscape of poor condition, and low perceived value relative to their scale and form. Where a landscape holds a high potential for mitigation it would also be considered to be of low sensitivity.</td>
</tr>
<tr>
<td>Negligible</td>
<td>N/A – it is not considered appropriate to include this category since no landscape is considered so unimportant that it may safely be disregarded.</td>
</tr>
</tbody>
</table>

**Criteria for Visual Amenity Impacts**

**Impact Magnitude**

Based on the Guidelines for Landscape and Visual Impact Assessment (Ref. 13.4) a series of visual impact magnitude category definitions were developed. These are detailed in Table 13.5. As with landscape impact magnitude elements of extent, duration, frequency and reversibility have been considered in the development of the LVIA criteria. However, it is noted that some of these characters are subjective in terms of LVIA and professional judgement in assigning impact magnitude ratings is considered a key part of the LVIA process.
Table 13.5 Impact Magnitude – Visual Amenity

<table>
<thead>
<tr>
<th>Magnitude</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Extensive change to existing view, loss of key characteristic features; introduction of anomalous and highly prominent or dominant new elements. Impact is more likely to be high if change is long-term or permanent.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Notable change to existing view (e.g. partial loss of key characteristic features); introduction of prominent, but essentially localised new features or elements; could include high impact change of a short-term or temporary nature.</td>
</tr>
<tr>
<td>Low</td>
<td>Minor change to existing view (e.g. limited loss of characteristic features), changes are evident, but not especially prominent and are generally localised impact is more likely to be low if change is short-term or temporary.</td>
</tr>
<tr>
<td>Negligible</td>
<td>Barely perceptible change to existing view and/or very brief exposure to view.</td>
</tr>
</tbody>
</table>

Receptor Sensitivity

Receptor sensitivity for visual amenity is a function of both the degree to which the receptor has an expectation of/or appreciation of a view or landscape, and the degree to which the receptor is physically able to access the view or landscape in question. The subjective criteria adopted have been defined in accordance with the Guidelines for Landscape and Visual Impact Assessment (Ref. 13.4) are detailed in Table 13.6. Visual amenity is defined in GIIP (Ref. 13.4) as “the overall pleasantness of the views they enjoy of their surroundings”.

Table 13.6 Receptor Sensitivity – Visual Amenity

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Receptors with a key interest and expectation of enjoying the view (e.g. residential receptors, tourists or people engaged in outdoor recreation whose attention is focused on the landscape) and/or a greatly valued existing view (e.g. a designated landscape, unspoilt countryside, recognised viewpoint or conservation area).</td>
</tr>
<tr>
<td>Moderate</td>
<td>Receptors at locations where the view is valued but not fundamental to the location or activity (e.g. people engaged in outdoor recreation that does not focus on an appreciation of the landscape). Visual receptors are less sensitive to changes to their view if the quality, condition and extent of the existing view is unexceptional (e.g. some high density suburban townscapes).</td>
</tr>
</tbody>
</table>

Continued...
Sensitivity | Description
--- | ---
Low | Receptors engaged in activities that either distract from the view or require concentration on the foreground, resulting in a minimal interest or appreciation of the view (e.g. people at work or motorists travelling through the area with the sole purpose of getting from one place to another and not for the specific enjoyment of the scenery). Receptors might very well appreciate the view if they chose to, but visual amenity is not the principal reason for them to be present. Visual receptors are less sensitive to changes to their view if the quality of the existing view is poor (e.g. industrial areas or derelict land).

Negligible | N/A – it is not considered appropriate to include this category since no visual receptor is considered so unimportant that it may safely be disregarded.

13.6.1.2 Modelling Undertaken

Receptor Sensitivity

Landscape character sensitivity is primarily a function of how robust (resilient or vulnerable) the existing landscape resource is to a given change in baseline conditions. In contrast, visual amenity is a function of how important the specific views and the general visual amenity of the landscape is to individuals or user groups.

Landscape and Seascape Character

Landscape and seascape character areas (LCA and SCA) were identified within the Survey Area, namely:

- Undulating Plateau LCA; and
- Black Sea Coastal SCA.

With regard to the Undulating Plateau, this LCA comprises a deeply undulating, extensively wooded landscape, which is common and characteristic of large areas of the plateau. The woodland is interspersed with open, cultivated land. Woodland is slow to establish and is valued as a natural habitat, but conversely it is effective at ‘absorbing’ development. In conjunction with the landform and with careful site selection, the woodland has the potential to accommodate development. Additionally, the use of existing open areas provides opportunities to minimise the need for woodland clearance. As such, based upon the criteria within Table 13.4, it is considered that the Undulating Plateau LCA is a moderate sensitivity receptor.

In contrast, based upon the criteria in Table 13.4, the Black Sea Coastal SCA is considered to be a high sensitivity receptor. It contains a relatively contained, linear landscape, limited to the coastline. This is valued for its combination of wildness and long ranging and expansive, panoramic views of the coastline and open sea, where any change has the potential to be highly visible and also to cause the coastal landscape to become fragmented. The combination of steep slopes, cliffs, rocky outcrops, beach and maritime vegetation, fronting the Black Sea, is sensitive to relatively small changes. However, importantly the open expanse of the sea is...
interrupted by commercial shipping that regularly uses the Black Sea shipping lanes off the
coast in the vicinity of the Project, and is therefore less sensitive to the introduction of the
Project fleet (anticipated to be an average of three vessels at any one time, refer to Chapter 5
Project Description).

Visual Amenity

In order to establish potential visual receptors a series of ZTVs have been created using the
tallest structure, i.e. the vent stack. The ZTVs were generated usingASTER 30 m resolution
Digital Terrain Model (bare earth) and analysed using ESRI ArcGIS 3D Analyst to determine ZTV
based on line of sight.

Visual receptors were identified as those within the modelled ZTVs (Figure 13.6 to Figure 13.8)
and have been calculated based on landform only (i.e. without taking account of woodland or
built-up areas) and therefore represent a worst case scenario. In the case of the landfall
facilities, on the basis of the visibility of the 30 m high vent stack (as noted above, the actual
proposed height of the vent stack is now 21 m). The modelling shows where any part of the
stack could possibly be visible, even if it will be only the very top. As such, it is considered to be
a highly conservative (i.e. worst case) estimate of the ZTV.

Table 13.7 describes the visual receptors within the ZTV and assesses the level of sensitivity of
these receptors to changes in visual amenity in accordance with the criteria set out in Table
13.6. Viewpoint photographs are shown in Appendix 13.1.
<table>
<thead>
<tr>
<th>Receptor Group</th>
<th>Description of Receptor Group Views</th>
<th>Receptor sensitivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recreational visitors to the shore, including the public beaches at Sukko and Anapa, and the private beach at the Shingari and Don holiday complexes.</td>
<td>The area is popular for its unspoiled nature and attractive views of coastal scenery and the sea. People on the beaches have open views out to sea to the west, and of the varied coastline to north and south. Views of coastal scenery tend to be highly valued by both local people and visitors using the beach for recreational purposes. From the beaches at Anapa, Sukko, the Shingari and Don holiday complexes, and other parts of the coast around the Taman Peninsula, there are open views towards the nearshore/offshore sections and construction vessels would be visible. However, all construction vessels would be seen in the context of commercial vessels on the existing shipping lanes and current port-related activities. Potential views inland towards the landfall section are prevented by the intervening coastal landform and woodland. In accordance with the criteria set out in Table 13.6, these receptors are judged to have a key interest or appreciation of the view and greatly value the existing view, refer to Viewpoint Photographs 1a, 1b and 1c.</td>
<td>High</td>
</tr>
<tr>
<td>Walkers on the coastal path along the cliff top.</td>
<td>Visual amenity is likely to be an important aspect for people choosing to use the coastal path. Views vary considerably depending on location and direction of view. There are panoramic views along the coastline, views inland over the rolling, wooded, plateau landscapes and open views out to sea. On other stretches, views are foreshortened by vegetation enclosing the path. There are views looking both inland of the landfall section from a short stretch of the path in its immediate vicinity and also looking out across the sea towards the nearshore/offshore sections. These receptors are judged to have a key interest or appreciation of the view and greatly value the existing view, refer to Viewpoint Photographs 2a and 2b.</td>
<td>High</td>
</tr>
<tr>
<td>Travellers on the Varvarovka to Sukko road.</td>
<td>People in vehicles have views over the rolling, wooded, plateau landscapes, the extent of which varies depending on levels of vegetation and whether the stretch of road is on a ridge or in a valley. These are kinetic views, fleeting and constantly changing for people in moving vehicles. Views include the landfall section from a short stretch of the road in its immediate vicinity. These road users are judged not to place importance on the existing view, refer to Viewpoint Photographs 3a and 3b.</td>
<td>Low</td>
</tr>
<tr>
<td>Receptor Group</td>
<td>Description of Receptor Group Views</td>
<td>Receptor sensitivity</td>

<td>----------------------</td>
</tr>
<tr>
<td>Potential Residents of the Clearing in the Woods “Lesnaya Polyana” development currently under construction.</td>
<td>There are views from this development site of part of the landfall section, which lies approximately 500 m away at its closest point. These potential receptors are judged to have a key interest or appreciation of the view, refer to Viewpoint Photograph 4. It is currently proposed that residential receptors will not be present until ca. 2015 or later (refer to Chapter 14 Socio-Economics).</td>
<td>High</td>
</tr>
<tr>
<td>Visitors to the Russian Orthodox and Armenian cemetery at Varvarovka.</td>
<td>People are likely to visit the cemetery for spiritual and emotional reasons, rather than specifically to enjoy the scenery. There are open views from the cemetery across the wooded valley selected for the landfall section, with the rolling landform of ridgelines forming the skyline beyond and the Black Sea in the distance. The landfall section area is partially visible, as is the area of the proposed access roads along the existing dirt tracks adjacent to the northern and eastern boundaries of the cemetery. In accordance with the criteria set out in Table 13.6 these receptors are judged to value the view but not find it fundamental to the activity of visiting the cemetery, refer to Viewpoint Photographs 5a and 5b.</td>
<td>Moderate</td>
</tr>
<tr>
<td>Travellers on the Varvarovka to Gai Kodzor road.</td>
<td>People in vehicles have very limited glimpse views of part the landfall section beyond the intervening hills and woodland from this road; these receptors are approximately 3 km North-East and they experience a wide panoramic view; the extent of these glimpse views of the Site would depend upon the type of vehicle. This section of road is included in the proposed access road. These receptors are judged not to place a lot of importance on the existing view, refer to Viewpoint Photograph 6.</td>
<td>Low</td>
</tr>
<tr>
<td>Residents living at North-East Varvarovka.</td>
<td>There are views of the existing unsealed road in the foreground where the proposed upgraded road would form part of the access road. This largely unsealed road is to be converted into a sealed road under existing permitted residential construction. There are also views of part of the landfall section from properties on the Eastern elevated area of Varvarovka facing South. The existing views are panoramic and long-range. The main Site is viewed at a distance of approximately 1.5 km. These receptors are judged to have a key interest or appreciation of the view and greatly value the existing view, refer to Viewpoint Photograph 7.</td>
<td>High</td>
</tr>
</tbody>
</table>

<th>Receptor sensitivity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Residents living at Sukko.</td>
<td>Properties on the seafront and some taller buildings set back from the front have open, uninterrupted views across the beach over the Black Sea. Levels of intervening activity on the beach vary according to the season. Other buildings in elevated locations further back from the seafront, including some development currently under construction; also have views towards the nearshore / offshore section. The landfall section is visible from upper storeys of some properties in elevated locations on the south-eastern side of the village, looking north and at distances of over 3 km. Receptors have fixed views from windows, with no alternative direction of view. In accordance with the criteria set out in Table 13.6. These receptors are judged to have a key interest or appreciation of the view and greatly value the existing view, refer to Viewpoint Photograph 8.</td>
<td>High</td>
</tr>
<tr>
<td>Agricultural workers on the land.</td>
<td>Views comprise agricultural land of vineyards, orchards and meadows in a wooded setting. People are likely to be working on the open land, which forms clearings of varying size within the wider wooded landscape. The extent of their views depends on whether they are on a ridge or in a valley and is also influenced by the proximity of woodland. Workers are likely to also gain views of the access roads; in particular the construction of the access road to the north-east of the landfall facilities will be clearly visible from certain locations for these receptors. In accordance with the criteria set out in Table 13.6 these receptors are judged not to place a lot of importance on the existing view, refer to Viewpoint Photographs 2a, 2b, 4, 5a, 5b, 6 and 8.</td>
<td>Low</td>
</tr>
<tr>
<td>Visitors to state nature reserve &quot;Utrish&quot;.</td>
<td>Visual amenity is likely to be an important aspect for the limited number of people choosing to visit the reserve; visitors must acquire a Government license to gain access. There are views from the south- and west-facing, wooded slopes of the reserve, looking out across the Black Sea. Depending on levels of intervening vegetation at any particular location, construction vessels would be visible working along the nearshore / offshore section, broadly parallel to and around 4 km off the coast, along with non-Project related vessels using the shipping lanes. In accordance with the criteria set out Table 13.6 these receptors are judged to have a key interest or appreciation of the view and greatly value the existing view.</td>
<td>High</td>

Photomontages

Photomontages have been produced to illustrate anticipated views experienced by a number of sensitive visual receptors, the locations of these are shown on Figure 13.9, and the photographs are shown in Appendix 13.1. The methodology used to produce these photomontages is included in Appendix 13.2: Photomontage Methodology. A list of the photomontages is set out in Table 13.8. Predicted impacts at these viewpoints are discussed in the following sections on the assessment of potential impacts and residual effects.

*Continued...*
13.6.2 Assessment of Potential Impacts: Construction and Pre-Commissioning

13.6.2.1 Introduction

This section identifies and evaluates the magnitude of the various predicted impacts that are likely to arise in relation to the Landscape and Seascape Character Areas and visual receptors identified in Section 13.5, as a result of the Construction and Pre-Commissioning Phase of the Project.

13.6.2.2 Project Activities with potential to cause landscape and visual impacts

The implementation of the Project involves activities that have the potential to impact both the terrestrial and the marine environments during the Construction and Pre-commissioning Phase.

Landscape and visual impacts would be most apparent during this phase and potentially due to unplanned events (see Section 13.7).

Terrestrial construction, pre-commissioning and operational activities affecting landscape and visual amenity, including habitat removal, site grading and the erection of industrial structures, will generate permanent modifications to the landscape. Temporary impacts to the landscape will also occur as a result of construction activities, which will include the operation of large mechanical equipment, power generators, soil stockpiles, parking of large construction machinery, and the generation of dust from construction activities. For further detail on the size of specific elements required for these activities, refer to Chapter 5 Project Description.

It will be necessary to clear all vegetation from the Pipeline route corridor and from any areas for temporary facilities. This will include vines planted in the vineyards, which cover a large proportion of this area. The areas cleared will be reinstated with some form of vegetation.
following the completion of the Construction and Pre-Commissioning Phase so this is considered to be a short-term and reversible impact (refer to Section 13.6.3 for details of assumed reinstatement). However, there will be a permanent change in the land use for the area occupied by the permanent landfall facilities and the permanent RoW as reinstatement of previous vegetation would not be possible in all areas, in particular on the permanent RoW. In areas directly adjacent to the RoW, graded bands of vegetation will be planted to re-vegetate the cleared areas.

The preparation and construction of the access roads between the M25 and the construction sites will include some new temporary hard surface roads, resurfacing of existing roads, upgrading dirt tracks to sealed roads, installation of localised sections of acoustic fencing (where necessary), and other minor improvements. It is anticipated that the majority of roads which are constructed on new routes will be reinstated after use; however, some are proposed to be retained where appropriate as agricultural access tracks, or for maintenance of Project facilities.

Offshore and nearshore construction impacts on seascape and visual amenity will result from pipe-laying vessels and support vessels (the construction spread) in the proximity of the shore and in the line of sight on the sea.

For further details on the duration of these phases refer to the construction schedule within Chapter 5 Project Description. For the purposes of this assessment, the Construction and Pre-Commissioning activities are estimated to be undertaken over a period of less than two years.

The relevant activities of the Project are summarised in Table 13.9.

**13.6.2.3 Assessment of Potential Impacts (pre-mitigation)**

During the Pre-Commissioning Phase works likely to affect landscape and visual amenity would be limited to two activities – three days of vessel operation to aid in the pumping of sea-water as part of hydrotesting, and onshore traffic movements to dispose of the small volume of liquid waste associated with cleaning and drying of the pipes. The landscape and visual amenity impacts associated with these activities are considered to be **Not Significant** and therefore not considered further. Consequently, the impacts discussed below relate only to construction activities.

As noted above, refer to **Chapter 3 Impact Assessment Methodology** for details relating to calculating the level of significance.

**Landscape Character**

With regard to the Undulating Plateau LCA, it is noted that this landscape of moderate sensitivity (as defined in Section 13.6.1.1) would be subject to direct impacts as a result of site clearance and construction work (e.g. clearance of existing vegetation and establishment of man-made structures). The extent and nature of this clearance (approximately 21.8 hectares (ha)), in comparison with the total area of the Undulating Plateau LCA within the Survey Area, is considered to be a limited geographical area. Additionally, it is a characteristic of the agricultural land cover that its impact on the landscape fabric varies, appearing as bare earth alternating to lush vegetation cover, throughout its seasonal management. The LCA would also experience impacts from other general construction elements, such as vehicular and labour.
force movements within the road infrastructure, potential noise and light emission. The Construction and Pre-Commissioning Phase associated impacts are considered likely to be adverse, direct, temporary, short-term and local (i.e. only in the Pipeline route corridor and access roads).

Some indirect impacts are also predicted such as the potential for coating of soil and vegetation with dust during the construction activities. The impact is assessed as adverse, direct, short-term (only during construction - estimated to be a maximum of two years), local (within the area of the Pipeline route) and reversible, because of the restoration of the landscapes after construction period. However, the outcomes of some of the construction activities, such as woodland clearance would be longer-term and effectively permanent but would not compromise the overall integrity of the wider woodland.

The reversibility of construction impacts would be largely dependent upon the successfullness of the restoration of the landscapes following the construction period in line with the Project restoration management measures set out in Chapter 22 Environmental and Social Management. Overall, it is considered that the magnitude of impact of construction activities on landscape character within the Undulating Plateau LCA is moderate, resulting in a Moderate and adverse impact which is considered significant.

Within the Black Sea Coastal SCA, it is noted that this seascape of High sensitivity would be impacted by the microtunnelling construction proposed for crossing the coastline, the only visible construction activities would be offshore, which would result in some limited, adverse, direct, temporary, short-term deterioration of the seascape, considered to be of low impact magnitude, resulting in a Moderate adverse impact.

**Visual Amenity**

Table 13.10 details the perceived magnitude of impact during construction for each of the receptors identified in terms of visual amenity. Refer to photomontages for the majority of receptor groups showing the Construction and Pre-Commissioning Phase, in Appendix 13.1.

Offshore construction vessels would be visible from much of the coastline, including the coastal path. From Sukko, offshore construction activity would be visible both from the beach and from properties on the seafront, in addition to some elevated or taller properties further inland. The offshore construction corridor would also be visible to people on the beach at the Shingari and Don holiday complexes and other beach users on Anapa beach, which stretches from Anapa Bay south towards the landfall section. Anapa Bay is a popular beach directly in front of Anapa, from where construction vessels would not be visible due to the screening offered by the headland to the south. It is not anticipated that sediment disturbed by the construction process will be visible in the sea from the coastline and therefore this is not considered as a potential visual impact, for details of plume modelling, refer to Chapter 12 Marine Ecology, which also notes that this impact will be monitored.
Table 13.10 Visual Impact Significance (pre mitigation) upon Receptors within the ZTV during Construction and Pre-Commissioning Phase

<table>
<thead>

<th>Significance</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recreational visitors to the seashore, including the public beaches at Sukko and Anapa, and the private beach at the Shingari and Don holiday complexes.</td>
<td>High</td>
<td>Moderate</td>
<td><strong>High</strong></td>
<td>People on the beaches have open views out to sea to the west. Construction vessels working on the nearshore / offshore section would be visible from beaches and other stretches of seashore. On the beach at Sukko, these would be at distances of between approximately 3 to 4 km, and the proposed microtunnel exit points would be behind the headland to the north and therefore not visible. All construction vessels would be seen in the context of commercial vessels on the existing shipping lanes. From the beach at the Shingari and Don holiday complexes, there would be open views of construction vessels working on the nearshore / offshore sections, including the microtunnel exit points, over 1 km away. Potential views inland towards the landfall section are prevented by the intervening coastal landform and woodland.</td>
</tr>
<tr>
<td>Walkers on the coastal path along the cliff top.</td>
<td>High</td>
<td>Low</td>
<td><strong>Moderate</strong></td>
<td>Views for people on the coastal path vary considerably depending on location and direction of view. From a short stretch of the path in the immediate vicinity of the landfall section, construction works would be visible looking inland. The extent of views of construction vessels working on the nearshore / offshore sections would vary greatly depending on the location of the viewer along the path. The closest element to the shore – the microtunnel exit points – would be approximately 800 m from the coastal path at its closest point. Further south, construction vessels may be seen working at around 4 km off the coast. North of the microtunnel exit points, supply vessels from Temryuk Port would be seen amongst other vessels on the existing shipping lanes.</td>
</tr>

</tr>
<tr>
<td>Travellers on the Varvarovka-Sukko road.</td>
<td>Low</td>
<td>Low</td>
<td>Low</td>
<td>Views of construction activity on the landfall section would be gained from a short stretch of the road in its immediate vicinity; the microtunnel entry points are approximately 200 m from the road at its closest point. From stretches of the road where the sea is visible through the woodland, for example the stretch between Sukko and the Shingari Holiday complex, there are likely to be glimpses of construction vessels working around 4 km off the coast. Generally, these are kinetic views, fleeting and constantly changing for people in moving vehicles.</td>
</tr>
<tr>
<td>Residents of the Clearing in the Woods “Lesnaya Polyana” development currently under construction.</td>
<td>High</td>
<td>Negligible</td>
<td>Low</td>
<td>Whether or not the visual amenity of residents of the Clearing in the Woods development would be affected, will depend on the progress of that residential development in relation to the Construction Phase of the landfall section (approximately 500 m away at its closest point). At the time of survey, there were no properties where the visual amenity of residents would be affected. Assuming the development is constructed prior to the commencement of the Project, partial views of the construction activities from a small number of properties is likely to be possible.</td>
</tr>
<tr>
<td>Visitors to the Russian Orthodox and Armenian cemetery at Varvarovka.</td>
<td>Moderate</td>
<td>High</td>
<td>High</td>
<td>There are open views from the cemetery across the wooded valley selected for the landfall section, where construction activity would be visible at distances of between around 500 m and 1 km. Construction vessels would be visible in the distance on the Black Sea, at least 2.5 km away, beyond the rolling landform of wooded ridgelines. There would be clear views of the construction and use of the access road along the northern and eastern boundaries of the cemetery for these receptors.</td>
</tr>
<tr>
<td>Travellers on the Varvarovka – Gai Kodzor road.</td>
<td>Low</td>
<td>Negligible</td>
<td>Not Significant</td>
<td>It is not considered that there would be views of the construction activity from this road due to the intervening topography and woodland vegetation. This road would be used as an access road for the Construction Phase only. Due to the significance, these receptors are scoped out of this assessment from this point.</td>
</tr>

</tr>
<tr>
<td>Residents living at North-East Varvarovka.</td>
<td>High</td>
<td>Moderate</td>
<td><strong>High</strong></td>
<td>People living in the new development on the elevated locations of the northeast of Varvarovka with windows oriented towards the landfall section and access roads are likely to gain clear views of the upgraded road and temporary acoustic barrier in the immediate vicinity. It is noted however, that this road is to be upgraded (to a sealed road) as part of existing permitted residential construction, irrespective of the Project. Further south, they may also view tall construction plant such as cranes and distant glimpses of the Project construction activities. The majority of construction operations would be screened by landform and woodland, however, construction of the access road (including the temporary acoustic barrier) would be short term. The impact of the construction of the access road and its use for Project-related traffic would be adverse, direct, temporary and short-term. The road would then be left in situ for future residential users of the proposed ‘Chateau’ residential development.</td>
</tr>
<tr>
<td>Residents living at Sukko.</td>
<td>High</td>
<td>Low</td>
<td><strong>Moderate</strong></td>
<td>Construction vessels working on the nearshore and offshore sections would be visible from properties overlooking the sea at distances of between 3 and 4 km. The proposed microtunnel exit points would be behind the headland to the north of Sukko and therefore not visible. From some properties in elevated locations with windows oriented towards the landfall section, upper parts of tall construction plant, such as cranes, are likely to be visible looking over and between buildings within Sukko, beyond the intervening, undulating, wooded landscape. The majority of construction activities would be screened by landform and woodland. The impact would be adverse, direct, temporary, short-term and local (only looking in one direction and at a distance of around 3 km).</td>
</tr>
<tr>
<td>Agricultural workers on the land.</td>
<td>Low</td>
<td>Low</td>
<td><strong>Low</strong></td>
<td>People working on the agricultural land of vineyards, orchards and meadows within the immediate vicinity of the landfall section would experience views of construction work and potentially the access roads. The extent of their views would depend on whether they are on a ridge or in a valley and would also be greatly influenced by the proximity of woodland.</td>

<tr>
<td>Visitors to state nature reserve “Utrish”.</td>
<td>High</td>
<td>Low</td>
<td>Moderate</td>
<td>Depending on levels of intervening vegetation at any particular location, construction vessels would be visible from south- and west-facing, wooded slopes of the reserve. Vessels would be working along the nearshore and offshore section, broadly parallel to and around 4 km off the coast, in the context of other vessels on the existing shipping lanes.</td>
</tr>
<tr>
<td>Recreational boat users.</td>
<td>Moderate</td>
<td>Moderate</td>
<td>Moderate</td>
<td>Due to the nature of the coastal topography and woodland, construction activities on the landfall section are unlikely to be visible. Boat users would have open views of construction vessels working on the nearshore / offshore sections. Supply vessels would be seen in the context of other commercial shipping in the vicinity.</td>
</tr>
<tr>
<td>Residents living close to the access roads.</td>
<td>High</td>
<td>Low</td>
<td>Moderate</td>
<td>The visual amenity of some residents living close to the access roads would be affected by increased numbers of vehicles passing through or close to affected settlements. Appendix 9.1: Traffic and Transport Survey notes an average increase in vehicular movements of less than 10% at the highest peak during construction on existing roads (refer to Chapter 14 Socio-Economics and Chapter 5 Project Description for more detail of specific routes and type of vehicle). Furthermore, certain residents would be also visually affected by the construction works required to upgrade a limited amount of these roads to the standards required for construction traffic, this would predominantly involve resurfacing works.</td>
</tr>
</tbody>
</table>
13.6.2.4 Mitigation and Monitoring: Construction and Pre-Commissioning Phase

Taking account of the potential impacts identified above, a Russian Landfall Construction Management Plan (CMP) will be prepared and communicated to contractors before any on-site works begin (Chapter 22 Environmental and Social Management). The CMP will detail the mitigation and monitoring measures, including requirements for the detailed landscape restoration plan, outlined in this section.

A range of design controls have been incorporated into the Construction and Pre-Commissioning Phase of the Project to ensure that the impact is minimised, as follows:

- Site selection away from settlements to minimise potential visual impact on residents;
- Alignment of proposed Pipeline to cause minimal damage to existing vegetation as far as practicable;
- Wooded nature of surrounding landscape minimises extent of direct visual impact and indirect impact on landscape character;
- Use of existing open land (agricultural fields) to minimise the need for further woodland clearance;
- Coastal crossing by means of microtunnelling to avoid the need for excavation of cliffs; and
- A buried pipeline is proposed as opposed to an above ground pipeline.

Where design controls have not fully mitigated an impact, further mitigation measures have thus been introduced. As described above, the key landscape and visual impacts would be associated with the Construction and Pre-Commissioning Phase; hence the majority of proposed mitigation measures are also related to that phase of the Project. Landscape and visual impacts during this phase would be minimised through:

- Protection of woodland and other vegetation to be retained, with the use of appropriate protective measures including fencing where appropriate;
- Erection of construction fencing and screening, and where necessary and practicable, the contractor shall use hoardings to screen unsightly, low-level construction activity close to publically accessible areas or residential properties;
- Phasing of construction where possible, to enable adverse impacts to be restricted to specific areas of the construction corridor at any one time;
- Phased consecutive programme of excavation and restoration (including prompt installation of proposed planting where practicable) to minimise areas of disturbed ground at any one time and to provide for direct placement of soils which would, in turn, minimise the amount of soil that has to be stockpiled and provide for a rapid reinstatement of the site;
- Progressive reinstatement of RoW in accordance with a landscape restoration plan following installation of the Pipeline;
- Rehabilitation and re-vegetation as soon as practicable;
• Avoidance of night-time construction activities as far as practicable;
• Utilisation of directional shielding for all lights used (including on construction associated vessels with the exception of navigational lights);
• Contractual requirement for an ethos of tidy working and regular removal of debris etc. and other materials with potential negative effect on the visual amenity and landscape character;
• Utilisation of suitable dust suppression methods where practicable to avoid dust plumes that would increase the prominence of the works, and which may otherwise coat nearby vegetation;
• Suitable weed control on temporary soil stockpiles and disturbed ground in accordance with the landscape restoration plan;
• Adoption of GIIP restoration practices and suitably experienced contractors;
• Appropriate planting in accordance with a landscape restoration plan (or equivalent). This plan would stipulate the planting of native vegetation in areas which do not have to remain open for operational reasons, to compensate for vegetation which has been cleared or disturbed; in particular areas around the landfall facilities and along the edges of the RoW where practicable including appropriately selected vegetative screening should be applied around the landfall facilities, and some retained access roads;
• Use of suitable vehicles and good vehicle maintenance on a regular basis to reduce visibility of exhaust emissions;
• An access road to bypass Varvarovka shall be routed so as to minimise disturbance to as many residences as reasonably possible;
• The proposed access road in proximity to the cemetery has been routed away from the cemetery boundary, in order to minimise the impact on visual amenity and landscape character. The selected route to the east is therefore separated from this receptor by intervening ground and furthermore, is proposed to be partially screened by planting in accordance with the landscape restoration plan. This planting shall be installed at the start of construction to maximise establishment time and effectiveness, and shall be maintained during the Operational Phase whilst the road continues to be used by the Project;
• Removal of acoustic barriers as soon as possible; and
• Reinstatement of newly constructed roads after construction where practicable or retention as agricultural access tracks and for maintenance.

The majority of construction impacts are considered to be reversible through the implementation of an appropriate landscape restoration plan during and after the Construction and Pre-Commissioning Phase. As such non-reversible impacts are limited to built elements, as they are completed within the Construction and Pre-Commissioning Phase, that may be visible to sensitive receptors (i.e. the vent stack and the permanent RoW).
13.6.2.5 Residual Impacts: Construction and Pre-Commissioning Phase

Table 13.11 presents a summary of the potential residual impacts to landscape and visual amenity arising from the Project during the Construction and Pre-Commissioning Phase, taking into account of the identified mitigation measures. Measures, stated in full above, are summarised, for ease of reference, in Table 13.11. In some occurrences the application of these measures may lead to a reduction in the adverse impact but may not be reflected in a lower categorisation of impact significance.

The majority of residual impacts are identified to be either of Low significance or Not Significant following mitigation and, as such, do not require any further management by the Project. However, a small number of Moderate (significant) impacts were identified for the following receptors:

- Parts of the Undulating Plateau LCA such as along the access roads, the landfall section, in the vicinity of the landfall facilities and at the microtunnel entry shaft;
- Recreational visitors to the seashore;
- Construction impacts upon the visual amenity of walkers on the coastal path at certain locations along the cliff top;
- Visitors to the Russian Orthodox and Armenian cemetery at Varvarovka;
- Residents living at North-East Varvarovka; and
- Recreational boat users.

These impacts would be short-term and result from the installation of physical infrastructure in a currently rural environment.

One key measure likely to further reduce these impacts is seen to be consultation with the affected stakeholders and their individual subjective assessment and concerns associated with the potential impacts associated with the Project (refer to Chapter 6 Stakeholder Engagement for further details). In particular, this may include:

- Further consultation with affected stakeholders (e.g. residents of Varvarovka, beach users, Shingari and Don holiday complex) to alert them of the proposed activity in detail as to what visual impacts may be expected;
- Discussion with the affected stakeholders as to their subjective opinion on the importance of temporary visual amenity impacts; and
- Detailed discussions with regard to scheduling of any particularly intrusive works, so as to ensure they occur at the time least likely to generate impacts to sensitive receptors.

13.6.3 Assessment of Potential Impacts: Operational (including Commissioning) Phase

13.6.3.1 Introduction

This section identifies and evaluates the magnitude of the various predicted impacts that are likely to arise in the relation to the landscape and seascape character and visual receptors identified in Section 13.5, as a result of the Operational and Commissioning Phases of the Project. This phase shall be referred to as Operational Phase henceforth as it is considered that the landscape and visual effects would be identical for these phases. The above-ground landfall facilities will be operated throughout the Project lifecycle and they will therefore cause a permanent impact to the landscape during the Operational Phase of the Project.

13.6.3.2 Project Activities with potential to cause landscape and visual impacts

During the Operational Phase, impacts would be mainly experienced from locations within the terrestrial environment with potential for additional impacts due to unplanned events (refer Chapter 19 Unplanned Events).

The above-ground landfall facilities would be operated throughout the Project lifecycle and they would therefore cause a permanent impact to the landscape during the Operational Phase of the Project. There would be a permanent change in the land use for the area occupied by the permanent landfall facilities and the RoW as reinstatement of previous, deep-rooted vegetation (such as grape vines) would not be possible in all areas, in particular within the permanent RoW area which is required to be kept clear (except for low growing vegetation such as grasses) (See Chapter 14 Socio-Economics for more details).

For the purposes of this assessment, it is assumed that all areas of vineyards which would have been cleared for construction would have been replanted with some form of crop or vegetation (except in those areas directly over the RoW area which is required to be kept clear (except for low growing vegetation such as grasses) and the landfall facilities, as required). This is reflected in the relevant photomontages.

All offshore activities would have ceased. The relevant activities of the Project are summarised in Table 13.12.

* The vent stack has been reduced from 30 m to 21 m since the ZTV analysis was undertaken

### 13.6.3.3 Assessment of Potential Impacts (Pre-Mitigation)

#### Landscape Character

Direct impacts on the Undulating Plateau LCA would result from the presence of permanent, above-ground plant and land cleared for the permanent RoW. The proposed landfall section facilities include a metering facility, pipeline inspection gauge (PIG) traps and electrical and instrumentation installations, for further details refer to Chapter 5 Project Description. All of the plant would be well below the top of the canopy top of adjoining woodland, except for the proposed 21 m high vent stack, which is likely to protrude above the existing canopy cover by a few metres. The effects on the landscape fabric itself would be largely confined to the landfall facilities, however, the impacts upon the landscape character would be adverse, direct, long-term (for the entire duration of operation) and localised.

Maintenance activity would be infrequent and relatively low-key.

However, the extensive woodland surrounding the Project is effective at ‘absorbing’ development by screening much of the Project. On this basis the operational impact upon the Undulating Plateau LCA would be low, resulting in a Moderate impact; therefore this is considered a significant impact, but a localised one relative to the scale of the LCA.

The short section of the coastal belt within the Black Sea Coastal SCA that would be crossed by the Pipeline route would experience very minor residual impacts on the SCA once installed, such as reinstatement of the vegetation above the micro-tunnelling route and occasional maintenance vessels. It is therefore considered that the impact magnitude upon the Black Sea Coastal SCA is negligible, resulting in a Low effect which is not considered a significant impact.

#### Visual Amenity

Table 13.13 details the perceived magnitude of impact during operation for each of the receptors identified in terms of visual amenity. Refer to photomontages for the majority of receptor groups shown in in Appendix 13.2.

<td>Negligible</td>
<td>High</td>
<td><strong>Low</strong></td>
<td>Upon completion of construction, the amount of additional traffic associated with the Project is likely to be imperceptible. Roads in close proximity to the landfall facilities which were newly constructed would have been reinstated as far as reasonably possible or retained as agricultural access tracks and for maintenance.</td>
</tr>
</tbody>
</table>
13.6.3.4 Mitigation and Monitoring: Operational

In terms of mitigation measures and monitoring, adverse effects on the landscape and visual amenity would be reduced where possible as set out in the landscape restoration plan, this would continue from the Construction and Pre-Commissioning Phase and throughout the Operational Phase.

To address the limited remaining operational landscape and visual impacts the following mitigation measures are recommended:

- Directional shielding for any permanent lighting at landfall facilities;
- On-going management and monitoring of appropriate native tree and shrub woodland;
- Planting in areas which do not have to remain open for operational reasons, to compensate for woodland removed. This would include areas of vegetative screening around the main plant and also along the edges of the RoW where practicable, including appropriately selected vegetative screening should be applied around the landfall facilities. Management of all planting must continue in accordance with the detailed landscape restoration plan, for the duration of the Operational Phase;
- Use of suitable vehicles and good vehicle maintenance on a regular basis to reduce visibility of exhaust emissions and vehicular noise;
- Appropriate vessel maintenance; and
- Roads and transfer sites in close proximity to the landfall facilities which were newly constructed to be reinstated as far as reasonably possible or roads retained for agricultural access and maintenance, in accordance with the landscape restoration plan.

13.6.3.5 Residual Impacts: Operational

Table 13.14 presents a summary of the potential residual impacts on landscape and visual receptors arising from the Project during the Operational Phase of the Project, following application of the identified mitigation measures. Measures, stated in full above, are summarised, for ease of reference, in the Table 13.14. In some occurrences the application of these measures may lead to a reduction in the adverse impact but may not be reflected in a lower categorisation of impact significance.

It can be seen that all of the residual impacts are identified to be either of Low significance or Not Significant following mitigation and, as such, are not considered to be of significance to visual or landscape receptors.

13.6.4 Assessment of Potential Impacts: Decommissioning Phase

13.6.4.1 Introduction

The Project is designed to be operational for 50 years. The decommissioning programme would be developed during the late Operational Phase. The decommissioning strategy is set out in Chapter 5 Project Description. It is likely that the technological options and preferred methods for decommissioning of such transportation systems will be different after 50 years, and the status of the Pipeline at the time of decommissioning would also impact on the chosen decommissioning methods. The eventual decommissioning requirements will be taken into account in the final design stage by ensuring that a range of possible options will be available.

Under all circumstances, decommissioning activities would be carried out according to prevailing statutory international and national legislation and regulations and GIIP regarding environmental and other potential impacts. An assessment will be undertaken and approval obtained during operation to confirm that the planned decommissioning activities are the most appropriate to the prevailing circumstances and future land use. The assessment would outline management controls and aim to demonstrate that the decommissioning activities would not cause unacceptable environmental and social impacts.

13.6.4.2 Assessment of Potential Impacts (pre-mitigation)

At this stage in the Project, the full extent of the decommissioning requirements is not known. However, it is likely that the receptors and impacts will be similar albeit less than those presented for the Construction and Pre-Commissioning Phase. These are outlined in detail in Section.

Given the timeframe involved there is also considerable uncertainty associated with what the baseline conditions will be like in 50 years, and whether the receptor sensitivity is likely to differ. There may also be additional sensitive receptors due to development and changes in land use.

Essentially two options are available for the decommissioning of the landfall section in particular; namely in situ decommissioning or pipe removal.

13.6.4.3 Mitigation and Monitoring

The potential impacts during the Decommissioning Phase will be similar to that of the Construction and Pre-Commissioning Phase. Mitigation and monitoring measures as outlined in Section 13.6.2.4 will therefore be relevant. If pipework is left in situ, and only above ground structures are removed, impacts on landscape character and visual amenity will be greatly reduced. Areas which had to remain open for operational reasons could also be available for appropriate tree and shrub planting, if other requirements for the land had not arisen. This would also be incorporated into a decommissioning landscape restoration plan in accordance with GIIP as applicable at that time.
13.6.4.4 Residual Impacts: Decommissioning Phase

Table 13.12 represents a summary of the potential residual impacts to landscape character and visual amenity arising from the Project during the Construction and Pre-Commissioning Phase and these would be similar albeit less during the Decommissioning Phase following application of the identified mitigation measures.

The Moderate residual impact significance upon the Undulating Plateau LCA, and the visual receptors (visitors to the seashore, walkers along the coastal path, users of the cemetery and recreational boat users) would be unavoidable, but short-term.

It is not anticipated that any long term significant impacts to the landscape character and visual amenity will arise from the Decommissioning Phase of the Project, due to the landscape restoration plan.

13.7 Unplanned Events

The potential for unplanned events is discussed in Chapter 19 Unplanned Events, factors noted there which could form adverse impacts on landscape and visual receptors are as follows:

- Fuel and oil spillages potentially leading to damage of vegetation - landscape and visual effects;
- Forest fires potentially leading to devastation of vegetation - landscape and visual effects; and
- Oil spillage potentially leading to temporary adverse impacts on the seascape character and visual amenity.

13.8 Cumulative Impacts Assessment

As part of the ESIA process, potential cumulative impacts as associated with the Project have been considered and are presented in Chapter 20 Cumulative Impact Assessment.

13.9 Conclusions

Based on the preceding assessment, it is concluded that during the Construction and Pre-Commissioning Phase both the Undulating Plateau LCA and the Black Sea Coastal SCA would be subject to Moderate adverse (significant) impacts. However, such impacts would be short term. Remediation measures such as planting and vegetation screening also help reduce the significance of impacts as vegetation becomes increasingly established.

During the Construction and Pre-Commissioning Phase the majority of residual impacts are identified to be either of Low significance or Not Significant following mitigation and, as such, are not considered to be of concern to the visual and landscape receptors, and therefore not significant to the Project (in accordance with the Chapter 3 Impact Assessment Methodology). However, a number of Moderate (significant) impacts have been identified in respect of the following receptors:
Recreational visitors to the seashore;
Walkers on the coastal path along the cliff top;
Visitors to the Russian Orthodox and Armenian cemetery at Varvarovka;
Residents living at North-East Varvarovka; and
Recreational boat users.

It is considered that the visual impacts upon recreational receptors in the vicinity of the coast (visitors to the seashore and holiday complexes, coastal path walkers and boat users) during the Construction and Pre-Commissioning Phase would potentially experience the more major impacts associated with the Project. These impacts are direct, temporary and short-term.

The residual impacts for landscape character and visual amenity during the Operational Phase are all identified to be either of **Low** significance or **Not Significant** and therefore not significant when design controls and mitigation measures are taken into account.

In conclusion, based upon this assessment of landscape character and visual amenity impacts, it is considered that the Project would not cause significant, permanent adverse effects to the identified receptors within the Study Area.

14 Socio-Economics

14.1 Introduction

This chapter presents an assessment of the potential socio-economic impacts resulting from the Project. In addition, mitigation measures designed to reduce, remediate or avoid potential impacts are described, and the residual impacts (i.e. impacts after mitigation measures are implemented) assessed.

14.1.1 Structure of Socio-Economics Chapter

Section 14.2 draws on the Project description (see Chapter 5 Project Description), the Scoping Stage and the stakeholder engagement process to identify potential impacts. Section 14.3 details the approach taken for the socio-economic baseline and impact assessment with regard to the spatial boundaries and defines the zone of influence for socio-economic impacts. Section 14.4 and Section 14.5 provide quantitative and qualitative baseline data commencing with a description of the data sources used in the baseline and followed by baseline summaries related to population and demography; economy; employment and livelihoods; land use; the local communities; public infrastructure and services; transport; accommodation and real estate; health, well-being and social infrastructure; the local tourism, recreation and leisure sector; and the local and regional fisheries industry.

Section 14.6 reports on the impact assessment in relation to socio-economic receptors, including during Construction and Pre-Commissioning and Operational Phases. Where relevant, this section presents the impact assessment at the pre-mitigation stage before presenting suggested mitigation measures, followed by the potential residual socio-economic impacts that would result following implementation of mitigation. Section 14.10 provides a summary of the key findings of this assessment.

14.1.2 Human Rights Due Diligence

Prior to concluding this chapter, Section 14.9 covers the Human Rights Due Diligence process that has been undertaken to complement the socio-economic impact assessment. This section explains the due diligence process that has been followed and examines human rights issues in respect of general policies and procedures, including labour and working conditions, local communities, supplier engagement, and security provision.

14.1.3 Relationship to the Community Health, Safety and Security Impact Assessment

A community health, safety and security impact assessment has been undertaken following the standards and guidelines of finance institutions and covering community health, safety, and security, as well as workforce occupational health and safety. The chapter also addresses the potential for impacts associated with construction traffic including road safety issues and severance. The results of this process have been documented in Chapter 15 Community Health, Safety and Security and in Appendix 15.1 Occupational Health and Safety. Appendix
9.1 Traffic and Transport Study has informed the findings of the assessments. The socio-economic and health impact assessment teams have worked together closely in undertaking these assessments.

### 14.1.4 Relationship to Other Chapters

An Ecosystem Services impact assessment has been undertaken following the standards and guidelines of finance institutions. The results of this process have been documented in Chapter 17 Ecosystem Services. The socio-economic and ecosystem services impact assessment teams have also worked together closely in undertaking these assessments.

This socio-economic impact assessment chapter has taken into account the findings of other chapters to inform and evidence the assessment of impacts on socio-economic receptors; including, but not limited to, Chapter 9 Air Quality, Chapter 10 Noise and Vibration and Chapter 13 Landscape and Visual.

The findings of this chapter are also supported by several appendices including Appendix 9.1, Appendix 12.2 Sediment Dispersion Study and Appendix 14.1 Fisheries Study.

### 14.2 Scoping and Stakeholder Consultation

#### 14.2.1 Impacts Identified During Scoping

A scoping exercise was undertaken in 2012 and resulted in the disclosure of a Scoping Report (Ref. 14.1) in December 2012, followed by associated stakeholder consultation. The aims of the scoping process were to identify the potential Project-related impacts, so as to inform further baseline studies, seek feedback from stakeholders on the Scoping Report and identify any additional issues to be considered in the ESIA process.

The Scoping Report identified receptors and communities with the potential to be affected by the Project Activities. For the purposes of this socio-economic assessment, certain communities (Gai Kodzor, Rassvet, Varvarovka, Sukko, Supsekh, and the town of Anapa) are referred to as the 'Local Communities' for the Project. These communities were identified as potentially Project-Affected Communities (PACs) in the Scoping Report, with the exception of Rassvet which has been identified since. The Scoping Report also identified potential impacts on these communities in relation to land use and ownership, the local economy and traffic.

Fishery businesses and individual fishers have been engaged since the scoping meetings in December 2012, and were also interviewed as part of the Fisheries Study in March and October, 2013. South Stream Transport met with representatives of RPK Briz Fishing Company, ZAO Morskoy Club, and OOO RAM Fishing Company. Briz Fishing Company was the only company to respond to a meeting request in March 2013. In October, 2013 a meeting request was sent to OOO RK Chernomorec but they declined to meet in person or provide feedback for the ESIA Report.

Fishers have raised concerns about the potential access to fishing grounds and also potential disruption on the migration routes of fish in the Black Sea from construction activities, including from light, noise and vibration. They were concerned that the Project could affect the migration...
routes of fish, which could potentially impact on fish catches and subsequently company profits. In addition, concerns were raised that the Pipeline might interfere with trawl gear. However, as the nearshore section of the Project Area is located within the Anapa Bank, in which bottom trawling is not permitted, the potential interaction with trawl fishing gears and the Project pipelines is thus reduced. Stakeholders also asked if the pipelines will be marked with buoys or on charts. The fishers also indicated that they would alter their trawling patterns once they knew the exact location of the Pipeline (Ref. 14.2, Ref. 14.3, Ref. 14.4 and Ref. 14.5).

Given the concerns that were raised and the importance attached to the issue by stakeholders, a fisheries study was undertaken (see Appendix 14.1) to assess potential Project impacts on fisheries. The Fisheries Study examined the potential risks of the Project to both fish stocks (including fish health and migration routes for various species) and the fishing activities of local fishers and fishing businesses.

Stakeholder consultation also identified some specific, primarily local, concerns that had not been covered in the Scoping Report, including questions about the safety of the Pipeline, local gas supplies, traffic, and access to local areas. A summary of stakeholder interests and concerns is provided in Chapter 6 Stakeholder Engagement.

### 14.2.2 Post-Scoping Stage Revisions

Following the Scoping Stage, refinement of the Project Description and further investigation of the baseline conditions within the Study Area (Section 14.3.3) enabled this assessment to conclude that there will be no significant impact in relation to certain issues. As such, these issues do not merit further consideration within the socio-economic assessment, and have not been the focus of baseline studies; this approach allows the socio-economic assessment to focus on the issues (and supporting information) pertinent to the Project. The rationale for screening out these potential impacts and risks is discussed below.

**Indigenous peoples:** Baseline studies have not identified any indigenous peoples, as defined by IFC Performance Standard 7, in the vicinity of the Project or the Local Communities. As such, no potential impacts on indigenous peoples were identified or assessed.

**Utilities services:** The Project, during both construction and operation, will make provision for meeting its electricity, sewage and telecommunications needs by means (e.g. by using diesel generators and using chemical toilets) that will be independent of existing systems serving domestic or commercial users within the Local Communities. Water will be obtained from a well in Sukko by agreement with the well owner; water will only be abstracted between October and April, and will be stored in water tanks at the landfall construction site for use throughout the year. Therefore, no potential impacts on existing users of utilities (specifically electricity, water, sewage and telecommunications) were identified or assessed. See Chapter 17 Ecosystem Services for further information.

**Utilities infrastructure:** The design of the Project has ensured that existing third party services will be located, marked, and either safeguarded or diverted prior to the start of construction, in accordance with owners’ agreements (see Chapter 5 Project Description). Accordingly, unless in case of accidental disruption, no potential impacts to these services, or to the domestic or commercial users of these services, were identified or assessed (see
Chapter 14 Socio-Economics

Chapter 19 Unplanned Events for consideration of the issues associated with accidental damage to third party property and utilities).

Since the Scoping Report was issued, the community of Rassvet has been identified as a potentially affected Local Community due to confirmation that construction traffic will travel through Rassvet. Therefore, potential socio-economic impacts on Rassvet have been considered in this chapter.

14.3 Spatial and Temporal Boundaries

14.3.1 The Project Area and Project Sections

The Project was described in the Scoping Report and a revised, detailed Project Description is provided in Chapter 5 Project Description.

The Project Area comprises three sections—landfall, nearshore and offshore—within which the Project’s activities will occur. The landfall section includes South Stream Transport’s landfall facilities (a fenced area containing metering and other equipment), 2.5 km of buried pipelines, and four microtunnels transitioning from land to sea. The short nearshore section starts at the exit of the microtunnels, approximately 400 m from the shore, and continues another 425 m to where the water is 30 m deep. From here, the offshore section begins and involves pipe-laying in deeper waters. Further information explaining the extent and nature of each section is given in Chapter 1 Introduction.

14.3.2 Location

The proposed site of the landfall section of the Project is located within the Anapa Resort Town (ART) municipal district, a district with Resort Status 1 (see Section 14.4.2.1 for further information on this status) on the Black Sea coast, in the Krasnodar region (or Krai) of the Russian Federation. It is set among rolling hills leading to the cliffs at the shore of the Black Sea.

The Project is located near to the six identified Local Communities (town of Anapa; Gai Kodzor, Rassvet, Supsekh, Sukko and Varvarovka). These communities have been identified either because they are the closest communities to the Project Area or, in the case of Rassvet and the town of Anapa, because they have the potential to experience impacts associated with construction and accommodation of the Project workforce.

The town of Anapa (estimated population 59,000) is the largest Local Community and is also the nearest large urban settlement, approximately 10 km to the north of the landfall section of the Project. With the exception of Anapa, the surrounding area is largely rural and includes a

---

1 This Resort Town status was established by Presidential Decree of 1994 No. 1954 and the Russian Government Executive Order of 1996, No. 591-p. Resort Town status recognises Anapa as a place of importance for tourism. The Resort Town status provides for certain land and development management regimes that are intended to safeguard the area’s environmental qualities so as to ensure the area’s suitability and appeal for resort and tourism related activities.
number of small to medium-sized communities near the landfall section of the Project. Of the remaining Local Communities, Varvarovka is the closest to the landfall section; it is located approximately 2 km northwest of the Project Area. All of the Local Communities are situated within the ART municipal district. The Local Communities are shown in Figure 14.1, together with the Project, including temporary and permanent access roads, and described in Section 14.4.3.

Novorossysk is located on the Black Sea approximately 50 km by road to the southeast of the Project landfall section, and its port may be utilised by the Project.

### 14.3.3 Study Area and Zone of Influence

Onshore and offshore socio-economic Study Areas were identified and mapped in the Scoping Report. The Onshore Study Area included the area within 2 km of the landfall section of the Project and also within a 300 m zone either side of potential (existing) access routes. Offshore, the Study Area was based on a 1 km wide zone following the nearshore and offshore route of the Pipeline, ending at the EEZ border between Russia and Turkey; this is the area in which the construction vessel spread will operate. The Study Area definition provided a primary frame of reference to consider the potential impacts arising as a result of the Project on its immediate surroundings. References in this chapter to the Study Area refer to the Onshore Study Area unless otherwise stated.

The Project may also give rise to economic impacts at a range of geographic scales, from the national scale (Russian Federation) to the regional scale (Krasnodar Krai), to the municipal district level (Anapa Resort Town (ART)). Any impacts within the Study Area will usually be at the local scale (the Local Communities), although this assessment has also identified the town of Anapa and Rassvet as Local Communities due to the potential for possible impacts associated with workforce accommodation and construction traffic. For the socio-economic impacts described in this chapter, the anticipated zones of influence are also identified. Economic impacts, for example, may be experienced at all levels, whereas community and transport-related impacts are generally local. Exceptions to this pattern are clearly stated under each respective impact assessment.

---

2 An access route is a collection of roads on which project traffic is carried, which (i) runs within a community, and (ii) may be expected to experience an increase of 30% in heavy traffic/overall traffic volumes, except for very sensitive receptors where an impact could be experienced with a 10% increase.

3 Hereafter, this level will always be referred to as the Anapa Resort Town (or ART where abbreviated) and refers to the entire municipal district administrative level which encompasses the Town of Anapa and the identified Local Communities, as well as other communities.

14.4 Methodology and Data

To assess potential socio-economic effects, data and information for the relevant baseline characteristics have been identified and considered. Data have been collected and presented at different spatial levels (national, regional, municipal district and local levels, as appropriate).

Socio-economic data and information included in this assessment have been obtained from a wide range of sources including secondary sources (i.e. existing data including census statistics, government or academic reports, etc.) and primary sources (i.e. new data collected through interviews, field surveys and stakeholder engagement activities, as described in Chapter 6 Stakeholder Engagement).

Where possible, the baseline characteristics section presents data for the Local Communities individually. For certain aspects of the baseline, data is only available at the Supsekh Rural District and Gai Kodzor Rural District levels. These cases are clearly indicated.

14.4.1 Data Sources

In the Russian Federation, there are generally good-quality social statistics at national, regional (Krasnodar Krai) and municipal district (Anapa Resort Town) levels. Some statistics at all three levels are collected by the national statistical agency Rosstat, while other statistical data are collected by the regional statistical agency Krasnodarstat or by the municipal district administration.

Data on local level administrative units, such as those within which the Local Communities fall, is available but limited. The extent of the available data was determined by contacting and visiting the local government administrations. Some current data were not available as they are not recorded at the local level. Therefore, primary data collection consisting of specific surveys and studies was needed to obtain the required data.

The following sections set out the secondary data obtained, the data gaps identified, and the primary data research and baseline surveys undertaken to supplement available secondary data.

Secondary Data

Secondary data and information was obtained from relevant regional and national bodies and for the identified Local Communities. The secondary data was obtained from publically available databases and by contacting local government authorities and explaining data needs with requests for access to data, and then accessing and recording the data in local government offices.

The main sources of secondary data include:

- Information provided by the Krasnodar Krai Territorial Authority of the Russian Federal State Statistics Service (ROSSTAT);
Chapter 14 Socio-Economics

- Information provided by the Anapa Resort Town (ART) municipal administration, Gai Kodzor Rural District administration, and Supsekh Rural District administration;
- Information published on the official website of the Russian Federal State Statistics Service (www.gks.ru);
- The Russian Federation Common Interagency Information Statistical Service (www.fedstat.ru); and

Data Gaps

Analysis revealed a number of data gaps which were most acute in the following areas:
- Demographics and migration;
- Economy, including the ART municipal district tourism sector and construction sector; and
- Housing and the property market.

Primary Data Collection

In light of the data gaps that emerged from the review of secondary data, a data collection exercise was undertaken with the aim of obtaining additional secondary data within the respective zones of influence. It sought to supplement the secondary data gaps as well as to verify and ground-truth the secondary data in order to better understand the key social issues and constraints. Primary data on socio-economic characteristics were collected during field visits in 2012, 2013 and 2014. These visits included observations of conditions in the Local Communities; meetings and interviews with local government authorities and local businesses including fisheries enterprises representatives and tourism entities; and a survey of existing traffic volumes near the landfall. The visits sought to:
- Observe and ascertain the prevailing socio-economic characteristics in the area;
- Conduct socio-economic baseline studies and collect data;
- Conduct qualitative interviews with local officials in order to build up a more detailed picture of the socio-economic environment in the Study Area and zones of influence, particularly within the identified Local Communities; and
- Observe and ascertain the condition of roads and other infrastructure that may be used by the Project.

Table 14.1 lists the stakeholder engagement activities to date which have informed the primary data collection efforts, as indicated by the purpose and topic and the meeting*. (Other meetings which have been held, including those which have informed the identification and prioritisation of stakeholder issues are presented in Chapter 6 Stakeholder Engagement.)

---

**Complete.**

### Information from Other Chapters

The socio-economic baseline has also considered information from other chapters, in order to inform and evidence the subsequent assessment of impacts on socio-economic receptors; including but not limited to **Chapter 13 Landscape and Visual**, **Chapter 15 Community Health, Safety and Security**, **Chapter 16 Cultural Heritage** and **Chapter 17 Ecosystem Services**, as well as Appendix 9.1 and Appendix 14.1. Other chapters of the ESIA Report are cross referenced where appropriate.
14.4.2 Data Assumptions and Limitations

Limitations

The following limitations apply to the data in this baseline:

- Some of the trend series data includes large movements between years, particularly for data during 2010 and 2011. It is likely that the completion of the 2010 data has enabled the statistical gathering agencies to revise statistics based on the 2010 Russian Census. However, it appears that a retrospective revision of data has not been carried out. While this can result in unexplained movement in the trend series data, it indicates that the latest data is likely to be more accurate;
- Where possible, a minimum of five years data has been provided. In some cases, it has not been possible to obtain a full five years of trend series data; and
- In certain circumstances, data is not always available; however, where possible, efforts have been made to obtain qualitative data in place of quantitative data.

It is considered that the above limitations do not compromise the integrity of the assessments made within this chapter.

Assumptions

The following assumptions have been made:

- The Project workforce in the nearshore and offshore sections of the Project will be specialised and non-local. This workforce will be accommodated on the vessels on which they work. The workers will come ashore only for brief periods in transit when rotating on and off the vessels. They are likely to come ashore at a port and proceed with onward travel. This port may or may not be in Russia;
- There will be no accommodation camp for the landfall section workforce; and
- Further to the statement in Chapter 5 Project Description that non-local construction workers will be lodged in the nearby towns and villages, it is assumed for the purposes of this assessment that they will lodge in the town of Anapa. This is based on the consideration that it is the town of Anapa, rather than the Local Communities, that is most likely to have a sufficient supply of suitable accommodation options available for requirements given the anticipated number of non-local workers.

Chapter 15 Community Health, Safety and Security states that South Stream Transport (or the Contractor) will undertake a Rapid Health Appraisal of the potential socio-economic and health impacts related to the preferred option(s) for workforce accommodation during the Construction and Pre-Commissioning Phase. The purpose of this appraisal is to avoid significant adverse impacts on Local Communities by identifying potential impacts and appropriate mitigation and management measures before the start of construction. The appraisal will include consultation with applicable local and regional authorities, including health and social service providers.
Chapter 14 Socio-Economics

14.5 Socio-Economic Baseline

This section provides a summary of the baseline methodology (including data sources and limitations), and describes the baseline socio-economic characteristics of the Project Area and Study Area. The section is structured as follows:

- Section 14.5.1: Geographic and Political Context;
- Section 14.5.2: Administrative Framework;
- Section 14.5.3: Introduction to Local Communities;
- Section 14.5.4: Population and Demography;
- Section 14.5.5: Economy;
- Section 14.5.6: Employment and Livelihoods;
- Section 14.5.7: Land Ownership;
- Section 14.5.8: Land and Marine Area Use;
- Section 14.5.9: Social Infrastructure and Services;
- Section 14.5.10 Tourism, Recreation and Leisure;
- Section 14.5.11: Fisheries;
- Section 14.5.12: Vulnerable Groups; and
- Section 14.5.13: Baseline Summary and Key Findings.

Information presented in Section 14.5.4 to Section 14.5.6 includes data for the Russian Federation, Krasnodar Krai and the ART municipal district, as well as at the Local Community level where available, in order to demonstrate how local demographic and socio-economic characteristics compare with the national and regional levels.

Information presented in Section 14.5.3 and Section 14.5.7 to Section 14.5.14 focuses primarily on the municipal district and/or local level (Local Community), with occasional reference to regional and federal level data where relevant.

14.5.1 Geographical and Political Context

14.5.1.1 Geographical Context

The South Stream Offshore Pipeline will extend across the Black Sea from the Russian coast near Anapa, to the coast of Bulgaria near Varna. It travels through Russian territorial waters, the Russian EEZ, the Turkish EEZ, the Bulgarian EEZ, and Bulgarian territorial waters.

14.5.1.2 Political Context

Russia’s political system is based on the 1993 Constitution and is a democratic federal law-governed state (Ref. 14.6). The President is the head of state, and the Prime Minister has responsibility for running the government. The Prime Minister is appointed by the president, and confirmed by the State Duma. Parliamentary elections were held in 2011 and presidential
elections in 2012, with Vladimir Putin coming to power and appointing Dmitry Medvedev as Prime Minister. The ruling party is United Russia.

Vladimir Putin was Boris Yeltsin’s successor and, since then, has been Russia’s dominant political figure. Putin served two terms as President before becoming Prime Minister, and then subsequently resuming the Presidency in 2012. Putin won presidential elections in 2000 and again in 2004. In the elections of 2008 Putin was barred by the Constitution from running for a consecutive third term as President, instead making way for Dmitry Medvedev (Ref. 14.7) who appointed Putin as Prime Minister. When Putin returned to the Presidency in 2012, Medvedev was appointed as Prime Minister.

14.5.2 Administrative Framework

14.5.2.1 Introduction and Overview

National, Regional and Municipal District Sub-Level Administrative Structure

Figure 14.2 shows the location of the Project in relation to the national, regional and municipal district levels of local government. A brief description of each level of government and relevant administrative framework is provided below.

Russian Federation

The Russian Federation consists of 83 federal administrative units of different extent and status. The administrative structure and organisation of the Russian Federation is described further in Chapter 2 Policy, Regulatory and Administrative Framework.

Krasnodar Krai

Krasnodar Krai is located approximately 1,000 km south of Moscow. It occupies the whole of Russia’s Black Sea coast and contains the country’s main beach resorts. This region has grown in popularity, particularly with tourists, since the fall of the Soviet Union as more Russians choose to take seaside holidays within Russia rather than along Ukraine’s Black Sea Coast.

The largest cities in the region include Krasnodar (with a population of 709,800), Sochi (334,300), Novorossiysk (227,900) and Armavir (189,100). Krasnodar Krai’s southern-most coastal city Sochi hosted the 2014 Winter Olympic Games; preparations for this resulted in considerable spending on infrastructure in the region, especially in and around Sochi.

Anapa Resort Town Municipal District

The ART municipal district is one of 38 administrative districts within Krasnodar Krai and it has the status of a city or municipal district (Ref. 14.8). ART has a growing population, which reached approximately 147,000 in 2012 (Ref. 14.9) and covers a total area of 982 km². It borders the Black Sea to its west, Temryuk District to the north, Krymsk District to the east and the port city of Novorossiysk to the south. The administrative centre is the town of Anapa (approximately 59,000 inhabitants) and there are 52 communities in total within the municipality, including the five designated as Local Communities for the ESIA: Gai Kodzor,
Chapter 14 Socio-Economics

Rassvet, Sukko, Supsekh and Varvarovka. The town of Anapa is also designated as a Local Community.

The ART municipal district was designated a health resort town in 1957 (Ref. 14.10) and is designated at a Russian federal level as a specially protected natural area (SPNA) (Ref. 14.11), under the category of ‘health improving (spa) resort area’ known as the Anapa Sanitary Protection Area (SPA) (Ref. 14.12). The Anapa SPA designation entails a series of development control regimes that apply to three different sanitary protection zones (SPZs) within the SPA, the general purpose of which is to protect the area from any activities that may adversely affect the natural therapeutic resources and sanitary conditions of the resort town area (Ref. 14.13) (see Chapter 2 Policy, Regulatory and Administrative Framework for further information).

The area around and between the communities of Gai Kodzor, Rassvet, Supsekh, Sukko and Varvarovka is primarily woodland or agricultural land. Vineyards account for most of the agricultural land, although the level of active cultivation varies. The pipelines will be located on a gently sloping plateau, which is separated from the Black Sea by a steep coastal cliff. Watercourses include the Shingar River and an unnamed tributary of the Sukko River; both rivers are intermittent (i.e. seasonal) and flow approximately north to south across the landfall section.

The state of the road infrastructure in the area is variable. Main roads linking the Local Communities to the town of Anapa are sealed and appear well-maintained. Some of the local roads between and within the Local Communities are simple dirt tracks. Traffic in the area varies according to the number of tourists in the area, and is highest during the summer months.

Municipal District Sub-Level Administrative Structure and the Local Communities

The ART municipal district includes one urban district, the town of Anapa, and ten rural districts. Two of these rural districts include the Local Communities identified for this socio-economic impact assessment), as shown below:

- Gai Kodzor Rural District, which includes the communities of Gai Kodzor and Rassvet; and
- Supsekh Rural District, which includes the communities of Supsekh, Varvarovka and Sukko.

5 SPNA zones can also be designated for a number of other purposes such as wetlands, protected natural landscape, traditional nature use, national parks, natural moments, etc.

6 Gai Kodzor Rural District contains four rural communities in total; these are Gai Kodzor village, Rassvet, Khutor (a smaller community), and Khutor Zarya and a total population of approximately 6,000 people in 2011 (Ref. 14.15). The total area of this Rural District is approximately 33 km².

7 Supsekh Rural District contains six rural communities in total. These are: Supsekh, Sukko, Varvarovka, Prostornyi, Bol'shoye Utrish and Mal'yi Utrish.
14.5.3 Introduction to Local Communities

14.5.3.1 Overview

Table 14.2 provides a summary of some of the key statistics for the Local Communities and is followed by a short description of each Local Community.

Sources: Area of Local Communities (Ref. 14.14). Population figures: Town of Anapa (Ref. 14.15); Gai Kodzor and Rassvet (Ref. 14.16); Sukko, Supsekh and Varvarovka (Ref 14.17). Note: Population figures rounded to nearest 10 people. Population for Rassvet does not include the adjoined village of Zarya, which has a population of approximately 1,180 people.
14.5.3.2 Local Community Profiles

Town of Anapa

The town of Anapa, located approximately 8 km north of the landfall section of the Project at its closest point, is the only designated urban district within the ART municipal district and is the seat of the municipal district administration. The town of Anapa's importance as a tourist centre is underlined by the designation of the wider municipal district as a 'resort town'. The town is one of a number of holiday resorts along the Black Sea coast and is a popular holiday destination for Russian tourists, especially for family holidays and children's activities. The town of Anapa has a population of approximately 59,000 (Ref. 14.15). It is served by an airport, railway station and bus station and is also easily accessible by road via the M25 which is part of the intercity regional road network in Krasnodar Krai (see Appendix 9.1 for further detail on transport infrastructure in the area).

As one of the main holiday resorts on the Black Sea coast, the town of Anapa relies heavily on tourism. The resident population increases seasonally when tourists visit the area; the high tourist season runs through July and August and can extend into September.

Gai Kodzor

Gai Kodzor (Figure 14.3) is the administrative centre of the Gai Kodzor Rural District. Gai Kodzor has a population of approximately 3,370 within an area of approximately 175 ha.

Figure 14.3 Gai Kodzor

The southern edge of the community lies approximately 3 km northwest of the Project Area and approximately 4 km from the landfall facilities. The section of road passing through Gai Kodzor is one that was considered as part of the access to the landfall section of the Project, but a bypass road has since been built around the community by Gazprom Invest and it will also be used by Project construction traffic. The community is built on either side of the existing paved road. Approximately 70% of the population is Armenian (Ref. 14.16). A community centre, a

8 As a sub-municipal district level administrative unit.
school, a bakery and various shops are located along the road running through the community. Site visits noted that some local residents of Gai Kodzor sell their produce along the road, e.g. fruit.

**Rassvet**

Rassvet is a small community located within the Gai Kodzor Rural District. Rassvet has a population of approximately 1,410 within an area of approximately 94 ha, and is bounded to the north by the M25. The community lies approximately 5 km north of Gai Kodzor community at the junction of the M25 and the proposed construction access route heading south towards the landfall section of the Project. To the immediate east of Rassvet is an adjoining but separate smaller community of Zarya (population approximately 1,180), while to the west and separated by a strip of open land is the much smaller and also separate community of Tarusin (population approximately 390). Similar to neighbouring Gai Kodzor, the population is nearly 60% Armenian, with the remaining 40% being of Russian ethnicity (Ref. 14.71).

The community has a school, nursery school, post office, community centre, car wash and tyre shop, hardware store, bottled water facility, supplier of sewage/water tanks, as well as a small number of shops along the main road. In addition to the retail premises, site visits noted that some local residents of Rassvet sell their produce, e.g. vegetables and watermelons, along the M25 road; while residents living on the main north-south road through Rassvet (ulitsa Kommunarov) sell goods such as potatoes along the road (Ref. 14.18).

**Sukko**

Sukko (Figure 14.4) is part of the Supsekh Rural District and lies on the coast. Sukko has a population of approximately 3,150 within an area of approximately 396 ha. Sukko Beach is located approximately 3 km south-east of the Project landfall section construction area, while the nearest residential properties on the northern outskirts of the town of Sukko are located approximately 2 km southeast of the Project Area, with the intervening land consisting of dense woodland. A water well in Sukko will be used to supply water during the Construction and Pre-Commissioning Phase of the Project; however, due to seasonal constraints, water will only be abstracted between October and April.

Sukko is organised along a single, long road that runs through the middle of the community with one end of this road leading to the beach, which is the main, easily accessible public beach between the town of Anapa and the Utrish Specially Protected Natural Area (SPNA). Tourism is well established in Sukko and there are more tourist facilities in Sukko than in the other Local Communities (including Supsekh even though Supsekh is a larger community) due to Sukko’s prominence as a tourist destination being located on a beach (the other Local Communities, excepting the town of Anapa, being located inland). The town has well-developed tourist infrastructure and services including recreation centres, fishing and horse riding facilities. Accommodation facilities in the community include over 300 hotels; seven health resorts, sanatoria and health improvement centres; and three children’s and tourist camps. One of the children’s holiday camps is located next to the public beach (Smena or ‘Time Off’), which is well known in the area. In addition, Sukko has a kindergarten, a sports centre and a healthcare facility, as well as many restaurants, shops and kiosks catering to visiting tourists. Many of the buildings in this community are four to five storeys high and appear to be hotels. Most other
buildings are one to two-storey detached houses. Marine activities include scuba diving, yachting and recreational fishing.

**Figure 14.4 Sukko**

---

**Supsekh**

Supsekh, located approximately 4 km north of the landfall section (refer to Figure 14.5), is the administrative centre of the Supsekh Rural District. Its population is approximately 8,760 and its area is approximately 635 ha.

Supsekh is close to the town of Anapa and, although physically separate, it appears to function as a suburb of the town of Anapa; a high proportion of its residents work in the town of Anapa, and access services and facilities there. The housing in the community is of a similar size and quality to that observed in Varvarovka. However, the community has a more extensive range of social infrastructure, including schools and community centres, and several retail and service outlets including supermarkets, a pharmacy and restaurants.

**Figure 14.5 Supsekh with the Town of Anapa in the Background**
Varvarovka

Varvarovka is the closest community to the Project. The nearest identified buildings are located to the north-west within approximately 1 km of the landfall section; the intervening land is agricultural in nature with some woodland. A Project transport route from the water well in Sukko (which will supply the Project) will run along the southern edge of the community. In addition, the community lies on a section of road that was considered for access to the Project landfall section during construction; however, a Varvarovka Bypass Road will be constructed as part of the Project and used by construction traffic to avoid construction vehicles travelling on the main road through Varvarovka during the Construction Phase.

Varvarovka (Figure 14.6) occupies an area of approximately 215 ha with a population of approximately 2,250 and is located within the Supsekh Rural District. The population is mainly ethnic Russian with a significant Armenian minority forming around 40% of the population. It is located approximately 2 km south-east of the community of Supsekh.

Varvarovka consists of two main streets, one asphalted (or paved), which are connected at several points by dirt tracks. Most houses are single or two-storey detached structures arranged along the hill which slopes through the community. Varvarovka has a number of amenities such as a nursery and a general school, a community centre and a sports centre along with a few small shops. The Kavkaz Winery (together with a separate but related firm, ZAO Agrifirm Kavkaz) is well-known for grape production and wine making, and is located in the community. This enterprise includes wine-processing facilities, a distribution and administrative centre and a wine shop, all located along the main paved road. Varvarovka is also the headquarters of Briz, one of two small commercial fishing organisations in the Anapa area.

**Figure 14.6 Varvarovka (Viewed from the Lesnaya Polyana site)**
**14.5.3.3 Shingari and Don Holiday Complexes**

Approximately 2 km south of Varvarovka, between Varvarovka and Sukko, are two neighbouring holiday complexes (tourist resorts) known as the Shingari and Don holiday complexes, which are not considered in this chapter to form part of any of the Local Communities. They are located approximately 1.5 km south of the landfall section. Shingari is a privately owned complex of holiday residences built on the coastal cliff top adjacent to the landfall section. There is a beach in front of Shingari immediately below the complex which is accessible to guests staying at Shingari by steps from the resort. The Don complex is located opposite Shingari on the north side of the roadway running between Varvarovka and Sukko, and its residents also have access to the beach via a path that runs on the outside of the Shingari complex perimeter boundary.

Shingari reported that it has capacity for approximately 300-370 guests and that it welcomes approximately 6,000 to 7,000 guests per year. It is a year round resort, although the peak season (during which time occupancy is 100%) runs from June to early October. The shoulder season starts at the beginning of May, during which time they typically achieve 50% occupancy. At other times, they tend to operate at approximately 20 to 30% capacity. Shingari mostly works with corporate clients and most guests are company employees who have been provided vouchers to stay at the complex by their companies. Most visitors are from different regions of Russia, with around 3% of visitors coming from other countries within the former Soviet Union. Around 150 people are employed by Shingari although this rises to 200 during peak season. Most employees are local and reside in Anapa.

The Don holiday complex has capacity for 50 guests, and it is understood that Don operates on a similar basis, although only for employees or other people associated with Russian Railways, and it is not open to the public (Ref 14.19) (see also Chapter 17 Ecosystem Services).

**14.5.4 Population and Demography**

**14.5.4.1 Population**

Russia experienced a steady decline in its population from 1991 through to 2009 due to declining birth rates, rising death rates and emigration. However, since 2010, the nation’s population has grown\(^9\), reaching 143.0 million in 2012 (an increase of 0.6% over the period 2007 to 2012) (Ref. 14.20). A similar trend is observed in Krasnodar Krai, where the population in 2012 was estimated at approximately 5.3 million, and population increased by 3.6% over the five years to 2012 (Ref. 14.15).

\(^9\) This reversal is likely due to a combination of increased confidence in Russia’s economic prospects as a result of continued steady economic growth and also government polices to stimulate population growth. One policy, known as the ‘maternal capital’ scheme provides vouchers worth approximately RUB 400,000 (approximately US$13,000) and which are given to mothers who have two or more children (this figure is indexed every year). This has been provided since 2007 and the vouchers can only be used for a limited range of purposes such as home improvements, education, and the mother’s pension savings.
In the ART municipal district, the population increased by 9.1% during the period from 2007 to 2012. In 2012 it was 147,200, with about 40% living in the town of Anapa itself (Ref. 14.15).

Of the Local Communities, the town of Anapa is the largest, with 59,000 people, followed by Supsekh with approximately 8,760 people. Varvarovka, Gai Kodzor and Sukko are relatively small at 2,250, 3,370 and 3,150 people respectively (town of Anapa data (Ref 14.15); Gai-Kodzor data (Ref. 14.16); Sukko, Supsekh and Varvarovka data Ref 14.17). Rassvet is the smallest of the Local Communities with a population of approximately 1,410 (Ref. 14.16).

The ART Municipal District, including the Local Communities, is experiencing a higher rate of population growth than that seen at the national and regional levels, owing to higher birth rates, lower death rates and positive net migration. The main factors contributing to migration growth are the influx of migrant labour for the construction, tourism and agricultural sectors, as well as a relocation programme run by the Russian military to resettle service personnel to the area on retirement (Ref. 14.21).

14.5.4.2 Demographics

The gender ratio at the national and regional levels is approximately 46% male and 54% female, while in the ART municipal district it is 47% male and 53% female. The profile of the Local Communities is similar (Ref. 14.15).

Whereas at the national and regional levels there has been a slight decrease in the proportion of the population that is of working age, in the ART municipal district during the period 2007 to 2011, the number of people of working age increased by approximately 14% (from 84,200 to 95,900). The biggest contribution to this increase comes from females (Ref. 14.15). This is in line with the economic growth that ART has been experiencing in recent years.

Ethnic Russians form the great majority of the population at national and regional levels, making up more than 80% of the population (Russian Federation data Ref. 14.22; Krasnodar Krai data Ref. 14.23). The ART district is characterised by a high proportion of ethnic Armenians (Ref. 14.24). The ethnic composition of the Local Communities is broadly as follows:

- Varvarovka: Russians, plus other ethnic groups (excluding Armenians) account for approximately 60%; and Armenians for approximately 40%;
- Sukko: Russians, plus other ethnic groups (excluding Armenians) account for approximately 75% and Armenians for approximately 25%;
- Supsekh: Russians, plus other ethnic groups (excluding Armenians) account for approximately 50% and Armenians for approximately 50% (Ref. 14.17);
- Gai Kodzor\(^\text{10}\): Armenians account for just over 70% of residents, with Russians accounting for around 26%. Other groups include Ukrainians, Yezidi\(^\text{11}\), Greeks and Tatars (Ref. 14.25); and

\(^{10}\) In 2011, the entire rural district has a population of approximately 5,980 people. Accordingly, Gai Kodzor and Rassvet together account for approximately 80% of the total population of the Gai Kodzor rural district.

\(^{11}\) A Kurdish ethno-religious group with Indo-Iranian roots.
• Rassvet: 60% Armenian, with the remaining 40% being of Russian ethnicity (Ref. 14.71).

Most recent migrants to the Russian Federation (almost 90% in 2010 and 2011) have come from the countries of the former USSR (Ref. 14.26). The regional and local migration profile is similar. In Krasnodar Krai in the first half of 2012 more than half (53%) of migrants came from Uzbekistan and 18% came from Armenia (Ref. 14.15). Migrants from these countries are the main immigrants to the ART Municipal District and Local Communities. They migrate to the area to work in tourism and agriculture and, particularly, construction (Ref 14.27; Ref 14.21).

14.5.5 Economy

14.5.5.1 Gross Domestic and Regional Product Indicators

Russian Federation and Krasnodar Krai

The Russian Federation is among the world’s largest economies. It is classified by the World Bank and International Monetary Fund as a developing economy and is heavily dependent on natural resources. Table 14.3 gives information on the GVA\textsuperscript{12} (i.e. GDP and GRP respectively) for the Russian Federation and Krasnodar Krai. In 2012, the Russian economy grew by an estimated 3.4% in real terms, down from 4.3% growth in both 2011 and 2010 (Ref. 14.26; Ref. 14.28).

Krasnodar Krai ranks eighth in the Russian Federation by gross regional product (GRP). Data for the region indicates that regional economic growth has been strong (Ref. 14.29).

Data on the GVA and GVA per capita for the ART municipal district is not available. However, refer above for information in relation to wage levels in the district.

\textsuperscript{12} GVA is a measure of the value of goods and services produced by an area, sector or producer minus the cost of the raw materials and other inputs used to produce them. Unlike GDP, GVA does not include taxes or subsidies on the goods and services. GVA is useful for comparing performance across different areas as it is often difficult to allocate taxes and subsidies sub-nationally.

Capital investment flows at the national and regional level grew between 2006 and 2011, with a slight downturn at the national level in 2009 following the global economic crisis of 2008 (Ref. 14.32; Krasnodar Krai data Ref. 14.9).

The ART Municipal District also experienced consistent growth over this period (Ref. 14.9). Investment has been concentrated in three key sectors: tourism, recreation and leisure; residential development; and agriculture (Ref. 14.24). No information regarding capital investment flows was available for the individual Local Communities.

14.5.5.2 Economic Sectoral Composition – Overview

Russian Federation, Krasnodar Krai and Anapa Resort Town

In 2010, the composition of the Russian Federation economy broken down into three overarching sectors (as measured by GDP) were as follows: services (60.6%); industry (35.4%); and agriculture (4.0%) (Ref. 14.26). In 2012, they accounted for 60.0%, 36.1%, and 3.9% of the economy respectively (Ref 14.33) (see Appendix 14.2 Economic Data).

In 2012 and at the next level down, wholesale and retail trade accounted for almost 20% of GVA\(^{13}\); while manufacturing accounted for a further approximately 15%. Extractive industries, including oil and gas production, account for more than 10% of economic output (Ref. 14.26). (See Appendix 14.2 for a more detailed proportional breakdown of the contribution made by different economic sectors to the Russian economy). In 2011, the Russian Federation became the world's leading oil producer and is the second-largest producer of natural gas. The Russian Federation holds the world's largest natural gas reserves, the second-largest coal reserves, and the eighth-largest crude oil reserves (Ref 14.34).

For Krasnodar Krai, the economy is dominated by construction (accounting for 19.5% of GVA in 2011); retail and wholesale trade (16.4%) and transport and communications (15.1%). Hotels and restaurants (the closest proxy indicator for the tourism sector) accounted for approximately 2.7% of output (Ref. 14.30). However, this figure would not capture other economic activity associated with tourism such as construction activity, transport, retail, real estate and other

\(^{13}\) The full title used by the Russian statistical agency Rosstat is 'wholesale and retail trade; repair of motor vehicles, motorcycles and personal and household goods'. Hereafter, we refer to the sector as the wholesale and retail trade sector unless otherwise noted.
services. (See Appendix 14.2 for a more detailed proportional breakdown of the contribution made by different economic sectors to the Krasnodar Krai economy). Construction work associated with the 2014 Winter Olympic Games in Sochi, as well as with tourism more generally along the Black Sea coast, is likely to have contributed to the increased importance of this sector in Krasnodar Krai, which has risen from being the fifth largest sector in 2007 to its current strong position in the economy.

At the municipal district level, the ART municipal district administration estimates that the two leading sectors are the tourism sector and the retail and services sector, each accounting for approximately 40% of economic activity. Construction is estimated to account for approximately 10% of economic activity, followed by agriculture (3% to 5%). Fisheries are estimated to account for less than 1% of economic activity in the municipal district (Ref. 14.35).

Local rural district administration officials estimate that tourism accounts for between 40% and 45% of the economy in the smaller, rural Local Communities (i.e. other than the town of Anapa) (Ref. 14.16 and Ref. 14.27). It is likely to account for the greatest share of the economy in Sukko, while some the other Local Communities are more likely benefit indirectly, in particular by way of their residents being employed in tourism sector businesses. For more detailed information on the role that tourism plays in the Local Communities, see Section 14.4.10.

**Fisheries**

Fishing in the Russian Federation contributed 0.2% to national GDP in 2010, 2011 and 2012 (Ref. 14.26 and Ref. 14.33). The industry production index for the fisheries sector was 98.5 in 2010 and 112.5 in 2011, indicating relatively strong growth in the value of output in the sector in 2011 after a small contraction the previous year (Ref. 14.26). In Krasnodar Krai, the equivalent figure for contribution to GRP was a constant 0.1% in each year from 2007 to 2011 (Ref. 14.30).

Comparable data for the fisheries sector at the ART municipal district level is not collected on the same basis as at the national and regional levels. However, it is estimated by the ART Municipal District administration that in that district in 2012, the sector contributed less than 1% to the municipal district’s economic output (Ref. 14.35).

**14.5.6 Employment and Livelihoods**

**14.5.6.1 Employment Trends**

At the national and regional levels, the labour market has been recovering in 2010 and 2011 from the 2009 downturn in employment (Ref. 14.36; Ref. 14.14.15). In contrast, the ART municipal district has experienced steady growth in employment in recent years and does not appear to have been as seriously affected by the global financial crisis (Ref. 14.24).

14 The index is an economic indicator measuring the value of production year on year as recorded for economic activity in the ‘Fishing’ sector. The index is expressed relative to the previous year in comparable prices at a base value of 100 such that a figure below 100 indicates contraction in the real value of output while a figure above 100 indicates an increase in the real value, or growth, in that sector.
In the Local Communities, the majority of residents work outside their local community. Sukko records the lowest proportion of people working outside their home community; whereas in Varvarovka and Supsekh more than four out of every five people employed work beyond their community (Ref. 14.17). This indicates that these communities are more likely to have strong economic links with the town of Anapa and the job opportunities provided there.

Seasonal jobs in tourism and related sectors are an important source of employment in the whole of the ART municipal district during the peak tourist season, as shown in Table 14.5. It is understood that this increase in seasonal employment opportunities effectively eradicates unemployment (or at least reduces it to very low levels) in the tourism season (Ref. 14.21). The data indicates that the number of seasonal jobs in the municipal district exceeds the number of people employed in regular jobs by almost two-thirds. The municipal district was not able to give information on the type of jobs performed, nor was it able to give information on the proportion of seasonal migrants in seasonal employment. However, jobs lasting less than one month are not accounted for in the regular employment numbers, so the number may include a variety of casual workers on short contracts. A local official in the Supsekh Rural District administration estimated separately that there are an estimated 500 temporary workers in Sukko in the tourist season working in hotels, trading and in other services such as cleaning (Ref. 14.27).

14.5.6.2 Unemployment

In Russia, unemployment rose in the wake of the global financial crisis to 8.4% in 2009, and has since declined, as shown in Table 14.6. The total unemployment rate has since dropped further to 5.4% in January 2013, which represents a record low for the last two decades (Ref. 14.37).

<table>

</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Source: Ref. 14.38

15 Total unemployment is measured through a regular labour force survey employing a sampling based methodology (i.e. the rate is estimated by surveying a subset of the population) and refers to the share of the labour force that is without work but available for and seeking employment.
Although a published unemployment rate is not available for Krasnodar Krai, using published statistics on the total number of unemployed and the economically active population (Ref. 14.15), it is estimated that the total unemployment rate in 2010 was 6.8%.

In the ART municipal district, a comparable measure of unemployment is not available. In order to be comparable, this calculation would need to include both registered and unregistered unemployment numbers, but only registered unemployment estimates are available. However, available information provided by local officials in 2012 indicates that unemployment levels are comparatively low, partly due to the strength of the tourism and construction sectors and also due to seasonal employment (Ref. 14.24). In March 2013, local officials suggested that unemployment in the district was the lowest in the whole of the Krasnodar Krai (Ref. 14.21).

In February 2014, local officials at the Anapa Resort Town Municipal District Administration reported that 616 people were registered as unemployed at that time, including 67 registered unemployed people in the Supsekh Rural District Administration (which includes the Local Communities of Supsekh, Varvarovka and Sukko). However, during the busy summer period the number of registered unemployed in ART falls to approximately 100 people due to the creation of temporary seasonal employment opportunities in the tourism sector. The administration reported that some local residents work during the summer, and register as unemployed to receive social security payments outside of the peak tourist season (Ref. 14.39).

The administration also reported some general characteristics of the unemployed in the ART Municipal District; approximately 60 to 70% of registered unemployed are women, nearly 35% are young people (i.e. 16 to 29 years old) and around 10% are of pre-retirement age\(^\text{16}\). No specific economic sectors are considered to represent a higher proportion of unemployed. Unemployment is considered a key factor contributing to low income households (Ref. 14.39).

Reliable unemployment rate data for the Local Communities were not available but they are expected to closely reflect the municipal district rates. During the summer tourist season, unemployment levels are reportedly very low in Supsekh Rural District as most people find employment in the hotel, restaurant and general tourism sectors. In mid-2013, during the summer peak season, local officials reported that only one person was registered unemployed in Varvarovka; nine in Sukko; and 58 in Supsekh (Ref. 14.17). Reliable unemployment data or estimates for Gai Kodzor and Rassvet were not available.

### 14.5.6.3 Migrant Labour

Demand for labour, including that generated by seasonal employment peaks associated with the summer peak tourism season, as well as the growth in construction activity in the ART municipal district that has been occurring since 2006, has resulted in new migration patterns at the local level.

Migrant workers come to the ART municipal district from a number of countries of the former Soviet Union states as well as other Russian regions, to work in construction, tourism

---

\(^{16}\) Pre-retirement age is a qualitative and commonly used term in Russia, generally understood by people using it to refer to the 10 years leading up to retirement age (which is 60 for men and 55 for women).
(particularly retail trading during the tourism season) and agriculture. For example, migrant workers from Dagestan are employed annually by Agrifirm Kavkaz. See Section 14.4.6.5 for more information specific to those workers.

Generally, the majority of migrants are men aged up to 30-35 who usually do not bring their families with them. Information on the average duration of stay is not readily available, but it is understood from local officials that workers in the hospitality and tourism sector typically stay for the duration of the peak tourism season before returning home again, and tend to return annually (Ref. 14.39).

Local officials report that the type of jobs performed by migrant workers varies depending on their country of origin. Generally migrants from Uzbekistan are employed in the construction and agricultural sectors, whereas migrants from Ukraine and Moldova are more likely to work in the services sector (Ref. 14.59). However, there is evidence to suggest that local people are also employed in the construction sector (see Table 14.7).

As of January 2014, approximately 2,000 foreign migrants were registered with the ART Municipal District Administration (this number does not include internal Russian Federation migrants). It is thought by local officials that the majority of these workers are from Uzbekistan, Moldova, Ukraine and Tajikistan, and that they have come to the area primarily to work in the construction sector (Ref. 14.39).

14.5.6.4 Employment Brokerage Services

The Anapa Employment Centre in the town of Anapa is a government recruitment agency that has previously worked with the private sector and has some experience of liaising with large companies in regard to brokering employment opportunities for local workers. Although the Centre has experienced mixed degrees of success more recently with companies that have stated that they wish to create up to 500 jobs, as to date, no local residents have been employed by these companies. The Anapa Employment Centre also helps local workers to access employment at health resorts (e.g. maintenance and landscaping work) in the lead up to and during the peak tourist season. This is recognised as a form of 'public work', whereby registered unemployed people are often taken on for this work, but also continue to receive social payments during the period they are undertaking such 'public work' employment. Local residents can be engaged on a public works project for between one to two months, and in 2013, 234 people were engaged in public work (Ref. 14.39).

The Anapa Employment Centre also runs a programme for vulnerable groups. Organisations employing local residents who are considered to be vulnerable (e.g. having a disability) receive compensation (Ref. 14.39). There are also some private recruitment agencies operating in Anapa Resort Town (Ref. 14.39).
14.5.6.5  Employment by Economic Sectors

Russian Federation, Krasnodar Krai and Anapa Resort Town

The main sectors in terms of employment for the Russian population in 2010 include the wholesale and retail\textsuperscript{17} sector (17.8% or 12.06 million employed people) and manufacturing and process industries (15.2% or 10.29 million people) (Ref. 14.24). In Krasnodar Krai, manufacturing and process industries are the leading sector for jobs, followed by wholesale, retail and repair (Ref. 14.15).

Table 14.7 shows employment in the ART municipal district for selected economic sectors from 2006 to 2010. The wholesale and retail sector is by far the largest employer but in other regards the employment profile differs from the national and regional picture: there is less dependency on manufacturing and processing, and more on agriculture and hotels and restaurants (reflecting the importance of tourism to the municipal district economy).

While the proportion of employment in hotels and restaurants as a percentage of total employment (approximately 2,600 workers in 2010 or 3.6% of total employment) appears relatively low when compared to other employment sectors and given the estimate by the ART municipal district administration that the tourism sector accounts for as much as 40% of economic output, it is still double the national average (1.8%). Further, the number reflects the annual average number of employees per annum working in a given sector and does not include those employed in small enterprises\textsuperscript{18} or those in employment for less than one month (Ref. 14.27).

\textsuperscript{17} The full title of this sector is “whole and retail business; repair of vehicles, motorcycles, household equipment”

\textsuperscript{18} The definition of a ‘small enterprise’ is provided in Federal Law N209-FZ of July 27, 2007 Small and Medium Business in the Russian Federation. Small and medium enterprises are consumers’ cooperatives and business (commercial) organizations, as well as individual entrepreneurs (that operate without creating a legal entity) and farms. Main criteria for identifying small enterprises are: a) the share of governmental bodies, foreign organizations, public and religious associations and other organizations that are not small and medium enterprises should not exceed 25%; b) the average annual number of employees should not exceed 100 persons (incl. 100); c) annual sale proceeds should not exceed 400 million RUR.

† Production and distribution of electricity, gas and water

Local Communities

Data on the breakdown of employment by sector in the town of Anapa is not available. However, given that the town accounts for approximately 40% of the population of the municipal district, the breakdown for the district is likely to be broadly representative of the breakdown by sector in the whole of the Anapa Resort Town municipal district. The main exception to this is likely to be that there will be less of a bias to primary industries such as agriculture and mineral extraction.
Data for employment by economic sector is also not available at the level of the other Local Communities. However, information provided by local officials suggests that in three of the smaller communities (i.e. Varvarovka, Sukko and Gai Kodzor) agricultural sector enterprises, and in particular grape-growing and winemaking enterprises, are the largest employers for people working within those Local Communities. In Varvarovka and Gai Kodzor, such enterprises also account for a majority of jobs within those communities (not including self-employed entrepreneurs and sole traders who may work from home). In comparison, the major employers in Supsekh include enterprises related to construction and manufacturing19 (Ref. 14.25 and Ref. 14.17). Local officials in the Gai Kodzor Rural District (including both Gai Kodzor and Rassvet) confirmed in early 2014 that a small number of local residents (estimated to be five people) have obtained employment on the construction of the Russkaya compressor station (Ref. 14.18). The town of Anapa is also an employment hub and many residents of smaller nearby rural communities work in the town of Anapa, including in the seasonal tourism industry.

Agrifirm Kavkaz and Kavkaz Winery

There are two firms, with their operations centred on Varvarovka (Agrifirm Kavkaz and Kavkaz Winery), which provide employment for up to approximately 100 people20. This includes approximately 40 to 70 workers cultivating the vineyard fields including during the harvest period. These workers are engaged annually from April until the end of the pruning period, usually in mid-November and are seasonal migrant workers, understood to have originated primarily from Dagestan. The remainder, approximately 30 people, include office staff and other workers (e.g. drivers, etc.) and these employees are local to the area (Ref. 14.40).

Migrant workers employed at the Kavkaz Winery live temporarily in cabins near the vineyards of this firm and the Varvarovka village cemetery. These workers farm the vineyards, harvesting and cutting grapes. A maximum of 45 such workers live in these cabins during the harvesting period (Ref. 14.41).

Another winery based in the Local Communities of similar size, Russkaya Loza (with 1,580 ha) is partly based in Supsekh and partly based in Varvarovka, which employs approximately 50 workers in Supsekh Rural District and a further 7 to 8 in Gai Kodzor Rural District (Ref. 14.17; Ref. 14.25). This vineyard is not directly impacted by land acquisition associated with the Project.

14.5.6.6 Livelihoods

Overview

The majority of employment in Russia is formal rather than informal, i.e. most people are employed in regular, paid positions, rather than pursuing subsistence or other informal livelihoods. Nevertheless, some individuals, particularly those on lower incomes such as

19 That is, the manufacturing and processing industries sector.

20 Agrifirm Kavkaz is concerned with the cultivation of approximately 400 to 600 ha of vineyard in the Study Area, while Kavkaz Winery is concerned with wine production.
pensioners, undertake additional economic activities to supplement and enhance their incomes (though they are not characterised as subsistence activities). For instance, there is a long tradition in Russia of household plots being used to contribute towards sustaining livelihoods and more recently, to enhance them.

**Local Communities**

In the ART municipal district, household plots account for 47% of agricultural output (Ref. 14.21 and Ref. 14.42). Many household plots are used to grow cherries, grapes, and other produce. Households use their own produce and also often sell it at local markets (this includes people registered as self-employed entrepreneurs) (Ref. 14.25). It has also been occasionally observed during site visits that some produce is sold along the roadside in Local Communities. It is possible that this activity makes a contribution to livelihoods.

Fishing is also evident and has been observed in Anapa. Based on observations of a small number of people fishing from piers, this is most likely for recreation rather than as a primary means to support livelihoods. However, according to local officials there may be a very small number of instances of fishing (i.e. from piers or the shore) to supplement livelihoods, although the officials were not able to provide any records or specific examples (Ref. 14.21).

It has been observed that local residents of Sukko appear to rent out rooms to visitors in the summer tourism season; presumably to supplement livelihoods (see Section 14.4.10).

Seasonal employment in tourism and the annual grape harvest is also an important source of employment in the ART municipal district (see Section 14.4.6).

**14.5.6.7 Income**

**Gross Average Monthly Wages**

In the Russian Federation, the gross average monthly wage in 2010 was approximately 21,000 RUB (Ref. 14.43). In Krasnodar Krai, the gross average monthly wage in 2010 was approximately 16,330 RUB (Ref. 14.15).

In the ART municipal district, the gross average monthly wage in 2010 was 14,000 RUB. The highest monthly wages in the ART municipal district were in the production and distribution of energy, gas and the water sector, followed closely by the transport and communications sector. Workers in the municipal district in the construction sector, and in the agriculture, hunting and forestry sector, received approximately 12,500 and 10,800 RUB per month, respectively, on a comparable basis. The hotel and restaurant sector, which is important to the local economy given the reliance on tourism, is the lowest paid sector with a gross average monthly wage of approximately 8,100 RUB (Ref. 14.15).

---

21 It was not possible to obtain an equivalent figure at municipal district level for workers in the fisheries sector; possibly because of the limited size of the sector in the district. However, at the national level, comparable data for the same year indicated that on average workers in the fisheries sector received an average gross monthly salary over 2.2 times that of workers in the agriculture, hunting and fishing sector. This pattern was also evident in statistics for the preceding five years.
Overall, when comparing the Russian Federation, Krasnodar Krai and ART municipal district across the whole economy, the gross average monthly wages in the ART municipal district are lower than average monthly wages in Krasnodar Krai and the Russian Federation for all sectors apart from agriculture.

### Subsistence Level (or Poverty Line)

In 2011, the official subsistence level\(^{22}\) in the Russian Federation was 6,369 RUB per month (Ref 14.44) and in Krasnodar Krai it was 5,931 RUB per month (Ref. 14.15). Nationally, the percentage of the total population with incomes below the subsistence level has fallen over the period from 2008 to 2012 from 13.4% to 11.0% (Ref. 14.45). Regionally, the percentage of the total population with incomes below the subsistence level fell from 17.7% to 12.2% over the same period (Ref. 14.46). At 5,976 RUB per month, the subsistence level calculated for ART is similar to the official subsistence level in Krasnodar Krai but lower than the national subsistence level. This reflects the relatively lower cost of living in rural areas (Ref. 14.24).

No estimate of the proportion of the total population with incomes below the subsistence level is available at the municipal district or local level. However, it is known that average pensions in the Russian Federation, Krasnodar Krai, and Anapa Resort Town in 2010 were between 7,476, 7,116 and 7,130 RUB, respectively. By the following year, 2011, average pensions had risen to 7,728 RUB in Krasnodar Krai indicating that pensioners’ incomes are generally comfortably above the local subsistence level. A figure for Anapa Resort Town was not available (Ref. 14.15).

### 14.5.7 Land Ownership

Two landowners have been identified in relation to Project-related land acquisition to accommodate the permanent landfall facilities, Right-of-Way (RoW) and permanent access road:

1. **Agrifirm Kavkaz**: which is in turn owned by a residential and resort property development enterprise, ‘Fond Yug’ owns the majority of the land that is required temporarily or permanently for the Project; and

2. **The Federal Forestry Agency (Rosleshoz)** which is a governmental body under the Ministry of Natural Resources and Environment which administers national and municipal forests in Russia, including designating protected forests and which is also responsible for reviewing proposals for change of status of forestry lands for other uses. The remaining smaller area of land is administered by this agency and is the land within the Right-of-Way between the agricultural fields.

Agrifirm Kavkaz, which is concerned with vineyard cultivation, is technically a separate entity to Kavkaz Winery, which is concerned with wine production. Agrifirm Kavkaz has approximately

\(^{22}\) The subsistence level is based on a calculation which takes into account the cost of a consumer goods basket, including for example food, utilities and household products, as well as mandatory payments and fees (according to RF Federal Law dated 24.10.1997 # 134-FZ “On subsistence level in Russian Federation”). It equates to a poverty line, which can be used to gauge the proportion of people living below a certain income level.
2,000 ha of land in total across the wider area, of which approximately 400 to 600 is planted with vineyard. Agrifirm Kavkaz was acquired by Fond Yug in 2008, primarily for the purpose of residential development. Fond Yug has contracted out the cultivation of the vineyards through Agrifirm Kavkaz (Ref. 14.40).

It is understood that Fond Yug bought Agrifirm Kavkaz and its 2,000 ha land holdings in 2008 with the intention to redevelop much of the land for master-planned residential and resort developments, retaining approximately 400 to 600 ha for use as vineyard. Fond Yug’s website states that the company is a residential, resort and leisure real estate developer with a total of US$500 million under investment (Ref. 14.47).

Fond Yug’s marketing materials indicate that the vineyard and winery businesses are valued by Fond Yug primarily for the prestige factor that the winery is able to bestow upon the residential developments, particularly the ‘Chateau Club Village’ residential development project. This proposed project offers prospective buyers the opportunity to have a small personal vineyard adjoined to their residence, and the expert advice and support of the Agrifirm Kavkaz staff to assist in the production of each resident’s own wine (Ref. 14.40).

14.5.8 Land and Marine Area Use

14.5.8.1 Existing Land Uses

The location of the Project Area is described in Section 14.2.1 and the administrative context is further explained in Section 14.5.2.

Land in and surrounding the Project Area is predominantly forested, interspersed with pockets of open land used primarily for agriculture (including vineyards) and the residential, commercial (including tourism-related enterprises) and community land uses and areas of the Local Communities themselves (see Figure 14.1, Figure 14.7 and Section 14.4.3). Further information on agricultural and forest land uses in the Project Area is given below in Section 14.4.8.2. There are also other land uses including military zones, cemeteries, and memorials within or near the Project Area.

Chapter 16 Cultural Heritage identifies the Varvarovka village cemetery, a mixed Armenian and Russian cemetery (RU-TCH-06), approximately 398 m north of the northern pipeline centre-line and close to the Gazprom Invest Road (permanent access road) and 100 m west of the South Stream Transport temporary access road to the microtunnel site. The Varvarovka village cemetery lies on the eastern edge of Varvarovka village, close to the Agrifirm Kavkaz vineyards. The cemetery is extensive and divided into family plots. It includes the common grave of Soviet soldiers and civilians killed in the fighting and executed by the fascist invaders in 1942 and 1943 (National Monument No. 380). Chapter 16 Cultural Heritage also identifies other cemeteries and churches in the wider area and provides more information on uses of land relating to Cultural Heritage. Refer to Figure 16.5 in that chapter for cultural heritage receptor locations.

The Utrish Nature Reserve, a state nature reserve covering the northern extent of the Caucasus Mountains, which includes some paths and trails for recreational users, is located approximately 3.5 km to the southeast of the landfall section of the Project.
14.5.8.2 Existing Land Uses within the Project Area

The landfall section of the Project Area can be divided into three parts: the landfall facilities; the buried pipeline (including construction corridor, potential transfer site and permanent pipeline RoW); and the microtunnels.

Landfall Facilities

The landfall facilities, and the upstream connection with the United Gas Supply System of Russia, will be located on an existing fallow field. There is no indication that the site is currently used for any commercial or recreational activities; nor that any trails cross the land.

Construction Corridor, Potential Transfer Site and Right-of-Way (RoW)

The construction corridor, including the permanent pipeline RoW for the buried section of the Pipeline, the potential transfer site and the associated temporary construction sites, overlap almost entirely with existing agricultural fields, except for two areas of forest. The main area of forest is an approximately 700 m strip of forest that separates two fields and which will be crossed by the Pipeline construction corridor and RoW. There is another much smaller area of forest at the southern end of the RoW that falls within the boundary of the microtunnel construction site and which is within the landholdings of Agrifirm Kavkaz. There is no evidence that either section of forest that falls within the construction corridor is commercially managed or used either by the respective owners or by any third party for economic or commercial purposes.

Figure 14.8 shows the existing land uses (agricultural fields, uncultivated scrub and forest) underlying the proposed construction corridor and temporary construction areas, including whether the fields are lying fallow, or contain mature or recently planted vineyard.
Historically, the cultivated fields, owned by Agrifirm Kavkaz, that fall within the Project Area were planted with vineyards; however, the land is now a mixture of fallow fields, scrub, and abandoned vineyard. The exception to this is the proposed potential 5.38 ha transfer site and the land within the temporary construction area for the Varvarovka Bypass Road. This land is currently productively used as vineyard but it is also within the confines of a proposed luxury residential development known as Chateau Club Village, the plans for which would retain as much of the vineyard as possible with the exception of sites for the construction of luxury residential homes (see Section 14.4.8.3 for further detail on this proposed development).

Agrifirm Kavkaz has indicated that the majority of the planted vineyards within the construction corridor, potential transfer sites and RoW have not been maintained over the last two to three years. This includes a range of mature and young (i.e. recently planted) vineyards (Figure 14.9). The young vineyard appears to have been planted in the past 24 to 30 months on previously fallow land along the route of the Pipeline in the landfall section.

Areas of shrub or uncultivated land adjoin the southernmost-affected field containing the mature vineyard.

**Figure 14.9 Abandoned Mature Vineyards near the Landfall Section**

*Microtunnels*

The entry shafts to the microtunnels are located near the south-western edge of an agricultural field containing a mature but abandoned vineyard. The microtunnels then pass under a very short section of existing mature but abandoned vineyard, shrub and uncultivated land, forested
land, coastal cliffs and the sea bed where they emerge onto the sea bed in the nearshore section (discussed under Marine Uses below). The microtunnels also pass under the Varvarovka-Sukko Road and a cliff top edge walking trail (the Mountains of the Caucasus trail). For more detail about this trail see Section 14.4.10.

14.5.8.3 Future Land Use

Anapa General Development Plan

The Anapa General Development Plan\(^{23}\) (Ref. 14.14) contains plans and development proposals for the Anapa Resort Town municipal district over the next 20 years, including proposals for the expansion of several towns and villages in the municipal district to accommodate forecasted population growth.

In particular, the Anapa General Development Plan makes provision for significant increases in population, and the physical expansion of the urban and residential area of the town of Anapa, Supsekh, Varvarovka (see Figure 14.10 which has been taken from the Anapa Resort Town General Development Plan, most recently issued with amendments in November 2013), Gai Kodzor and Sukko. For Rassvet, it makes provision for a more modest increase in population (ca. 15%), with the provision of some additional facilities. The Anapa General Development Plan does not set out any timetable for implementing the plan.

In relation to land use near the Project, the Anapa General Development makes provision for an increase in the area of Varvarovka from approximately 200 ha to just over 600 ha over the plan period to accommodate a corresponding increase in population from approximately 2,000 to approximately 8,000 people over the plan period. This increase would be achieved by redesignating existing agricultural fields, forest and scrub areas mainly to the south of the existing limits of the village including land owned by Fond Yug, to residential development zones. This would include development of an urban residential extension or satellite to Varvarovka on the south side of the Pipeline alignment to the immediate north of Shingari. Part of this area overlaps with the outermost Safety Exclusion Zone during the operational life of the Project (i.e. between 345 m and 410 m from the outermost pipelines); however, the Anapa General Development Plan allows for ‘cottage development’ which is permissible within the development restrictions applicable within the outermost Safety Exclusion Zone\(^{24}\).

The plans in the Anapa General Development Plan are aspirational and thus there is uncertainty as to when the development proposals will be fully realised. However, given the overlap between the proposed developments by Fond Yug and the future residential extensions to Varvarovka (see below), it is likely that some developments will proceed over the short to medium term. Figure 14.10 shows the existing and designed (i.e. future proposed) urban limits of Varvarovka.

\(^{23}\) Full title: ‘Master Plan of Resort-City Anapa City District, Volume III - Materials to substantiate the general plan of Anapa city district in relation to settlements’.

\(^{24}\) Onshore, to be put in place during the Operational Phase.
Figure 14.10 Anapa General Development Plan – Proposal Plan for Varvarovka
Current Development Proposals

There are several development proposals affecting land within and around the Local Communities. Table 14.8 sets out proposed investment projects in the Local Communities together with the cost of each investment and the expected construction duration.

</tr>
</tbody>
</table>

Source: (Ref. 14.24)

* Project construction duration is estimated based on best available information. Despite the dates shown, some projects may experience delays and so the dates shown should be taken as a guide only.

In addition to the projects currently under development shown in Table 14.8, Fond Yug plans to implement several investment projects in Varvarovka and the surrounding area. These include several residential projects (see below), a plan to construct an electrical substation to serve Fond Yug’s residential developments (Ref. 14.47) and a plan to widen the main road through Varvarovka (Ref. 14.17). There is also a proposal by another winery based in Gai Kodzor to construct a wine-tasting facility in Gai Kodzor (Ref. 14.25).

Table 14.9 sets out residential projects that are proposed. Of these, ‘Sunny Hills’, ‘Reserved’ and ‘Utrish’ are all more than 2 km from the Project.

Of the Fond Yug proposed developments, the site of the proposed Lesnaya Polyana housing development is located northwest of the microtunnel entry pit just beyond the outermost operational exclusion zone (Exclusion Zone 3 / A-class) as shown in Figure 14.11. Lesnaya Polyana is divided into approximately 160 plots, varying in size from 600 m² to 1,700 m² (Ref. 14.48). In October 2012, the development was on hold with no date set for construction to start; however, as of March 2013, construction of an access road and site levelling had been carried out. Prospective buyers could reserve a land plot and it is understood that approximately 1.5 ha worth of plots have been sold as of October 2013. As of February 2014, the internal street has been made and the site has been supplied with electricity, while water is in the process of being supplied also. Construction of housing is planned to start at some point in the next two to three years (Ref. 14.49).
The resort-residential project ‘Anapolis’ is located south of the Pipeline, overlapping in part with the outermost operational exclusion zone (although in this zone, the Anapa GDP allows for ‘cottage development’, which is permissible within the development restrictions applicable within the outermost onshore Safety Exclusion Zone 325).

The ‘Chateau Club Village’ development is located on the north-eastern edge of Varvarovka just outside of the officially designated boundary or urban limit of the community. (It is presumed that the development, although residential, is permissible despite being outside of the official boundary / urban limit of Varvarovka, as it is essentially comprised of small vineyards rather than being a dense residential development). The development has been placed on hold for the duration of the construction of the Project as an agreement has been concluded with the developer (Fond Yug) to use the road through the site as a temporary access road (i.e. for the Varvarovka bypass road) (Ref 14.49).

### 14.5.8.4 Existing Marine Area Use

In the marine section of the Project Area, fishing and commercial shipping are the principal socio-economic activities.

#### Fishing

Most commercial fishing occurs in waters out to a depth of approximately 100 m. These waters are located within the 12 NM territorial water limit. Fishing generally occurs in the nearshore section, and shallower regions of the offshore section; the majority of the offshore section of the Project Area is not used for fishing.

Further detail in relation to fisheries – including fishing activities, grounds and the people who rely on this industry – within the Project Area is provided in Section 14.4.11 and Appendix 14.1.

#### Shipping Routes

Numerous shipping routes traverse and intersect across the Black Sea, connecting all the Black Sea countries. The Pipeline will cross several designated commercial shipping routes as well as routes used by passenger ferries that travel between Russian ports, mostly catering to summer season tourist visitors.

For further information on shipping routes, see Appendix 9.1.

Sub-Sea Cables
A number of subsea telecommunication cables pass through Russian territorial and EEZ waters; the offshore pipeline route will cross six cables, four of which are telecommunications cables, while the other two serve unknown purposes and are understood to be out of service. The routes of these subsea cables are illustrated in Figure 5.34 within Chapter 5 Project Description. Chapter 5 also contains further information in relation to the cables, their owners and operators, the crossing agreements that will be put in place and the techniques used to safely lay the pipelines where they cross the cables.

Recreational Activities
There is some recreational use of the sea (e.g. swimming, diving) near the Project Area at Sukko beach and within nearby waters (see Section 14.4.10.2).

Oil and Gas Licence Area Exploration Activity
Rosneft OAO, a Russian oil and gas company, has licences for oil and gas exploration concessions off the coast of Krasnodar Krai in the Black Sea. The company's concession blocks in the Black Sea off the Russian coastline include the Tuapse Trough, West Chernomorsky and the South Chernomorsky offshore areas (Ref. 12.16). Figure 18.3 in Chapter 20 Cumulative Impact Assessment shows these concession blocks.

According to Rosneft's 2012 Annual Report (Ref. 14.54), the Tuapse Trough has a potential recoverable resource estimated at approximately 1.2 billion tonnes of oil equivalent and that 3D seismic work totalling approximately 4,200 km$^2$ was completed in 2012, whilst 3D seismic data obtained earlier have been processed. The West-Chernomorsky area has an estimated recoverable resource equal to approximately 1.4 billion tonnes of oil equivalent within a block area of approximately 9,000 km$^2$. Rosneft has carried out seismic works to study the area and has identified six promising formations. Rosneft press releases (Ref. 14.55) report that two exploration wells are to be drilled in 2015 to 2016 in line with license obligations. The South-Chernomorsky area has a recoverable resource of approximately 0.47 billion tonnes of oil equivalent, whilst the area has been subject to 2D seismic surveying in 2012.

South Stream Transport has met with Rosneft to discuss potential interactions between their oil exploration activities and the Project. However, further information detailing Rosneft's exploration locations and programme are not available at the time of writing.

14.5.8.5 Future Marine Area Use
Plans for future development are understood to include two new telecommunication cables: one between Myskhako (City of Novorossiysk) and Cape Utrish, and the other between Cape Utrish and Cape Zhelezny Rog. No route-specific information was available at the time of writing.

Apart from this, there are no known proposals to develop new uses or activities, or to intensify existing uses and activities, in either the nearshore or offshore sections of the Project.
14.5.9 Social Infrastructure and Services

The town of Anapa is the primary hub in the Anapa Resort Town municipal district for services and facilities. The town’s social infrastructure is more developed than that of the surrounding rural communities within the ART municipal district and includes community and leisure centres, libraries and museums. All households have electricity and mains water and gas supply. The Local Communities also have a range of community facilities including community centres and post offices. Further information in relation to housing, utilities and educational services follows below. For information on health infrastructure serving the municipal district and Local Communities, see Chapter 15 Community Health, Safety and Security.

Figure 14.12 shows the social and recreational infrastructure within and near to the Local Communities surrounding the Project.

Social, Tourism and Recreational Infrastructure within the Local Communities
14.5.9.1 Housing

Figure 14.13 shows that the number of dwellings reached almost 2.04 million in Krasnodar Krai municipal district in 2011. It also shows that the number of dwellings in the Anapa Resort Town municipal district reached 54,400 in 2011, evenly divided between the urban district (town of Anapa) and the 10 rural districts.

Thus, from 2006 to 2011, the total housing stock grew by approximately 18% in Krasnodar Krai and approximately 40% in the ART municipal district level, i.e. more than double the growth rate at the regional levels. The considerably higher rate of growth at the municipal district level is evidence of a construction boom related to the strong rates of growth as a result of inward migration and the development of local tourism.

**Figure 14.13 Number of Dwellings, Rural and Urban**

Field observations indicate that most houses in the Local Communities are well built and maintained. An example of housing typical in the area is shown in Figure 14.4.
On average, house prices are higher in the city of Krasnodar than in the ART municipal district; however, the price of apartments is lower in Krasnodar (Ref. 14.56). In the ART municipal district, the average house price is 45,000 RUB per square metre. Houses in the town of Anapa itself can cost up to 15 million RUB (Ref. 14.21). Prices in the Local Communities are variable.

Location and amenity play an important role in influencing retail house prices as well as rental prices. Property prices rise closer to the town of Anapa, and also depending on the level of amenity. Supsekh, which is relatively well supplied, and as the closest Local Community to the town of Anapa, commands relatively higher prices for rent. At the other end of the scale, Varvarovka, which is more distant and has few amenities, is the cheapest Local Community in the Supsekh Rural District area in which to rent or buy property (Ref. 14.16, Ref. 14.21, and Ref. 14.27).

Rental demand is strongest during the tourist season, which runs from May to September, peaking in June, July and August, when it is near capacity. There is lower demand for rented properties outside the tourist season in all Local Communities.

14.5.9.2 Community Relations

All local officials interviewed agreed that community relations, within and between communities, in the area are generally harmonious and that the area is considered to be a safe and pleasant
place to live. The local officials also stated that there are no tensions related to migration and that the various ethnic groups are well integrated (Ref. 14.16, Ref. 14.21, and Ref. 14.27).

14.5.9.3 Utilities

The ART municipal district has a lower standard of utility infrastructure than either the Krasnodar Krai or the Russian Federation as a whole. However, improvements are occurring, and increasing numbers of households are being connected to a mains water supply and the sewerage network.

There is considerable variation amongst the Local Communities with respect to utility provision. All households in the Local Communities have electricity supply. For example, all households in Supsekh and Gai Kodzor have mains water supply compared with 80% in Varvarovka, and only 50% of households in Sukko; the remaining households obtain water from wells on their property (Ref. 14.16 and Ref. 14.27).

Very few households in the Local Communities are connected to public sewers and most households rely on septic tanks. The exception is Supsekh, where approximately 50% of households are connected to the public sewer system, compared to approximately 10% of in Sukko and no households in Gai Kodzor and Varvarovka (where all households are understood to be served by septic tanks) (Ref. 14.16 and Ref. 14.27).

All households in Supsekh, and 75% of households in Gai Kodzor, are provided with piped gas supply. The gas supply has recently been expanded in Supsekh; between 2009 and 2012, an additional 5 km of gas pipelines were installed so that the whole community is supplied with gas (Ref. 14.27). Varvarovka and Sukko, however, do not have piped gas. Residents of these communities would like to be connected to the mains gas supply, and have expressed this wish during public consultations in these communities (see 14.2.2 and Chapter 6 Stakeholder Engagement).

14.5.9.4 Education

All the Local Communities have nursery and primary schools, as well as “general” schools that educate children up to age 15. Gai Kodzor and Supsekh each have post-15 high schools.

The public tertiary education system within the ART municipal district offers a wide range of courses with a vocational or technical focus, including construction and engineering. There are no reported skill shortages in the local area (Ref. 14.21).

14.5.10 Tourism, Recreation and Leisure

14.5.10.1 Anapa Resort Town

As noted in Section 14.4.5.2, tourism is a major contributor to the economy of the ART municipal district, accounting for approximately 40% of the ART economy (Ref. 14.35). The two main centres for tourism and tourism infrastructure, including accommodation, in the area are the town of Anapa and, to a lesser extent, Sukko.
Some 4.5 million tourists visited ART in 2012, including 3.5 million in the tourist season (May to September). Tourism is developing rapidly and from 2008 to 2012 the number of tourists coming to Anapa increased more than fourfold (Ref. 14.21).

The ART municipal district has numerous premises to accommodate tourists including sanatoriums, hotels, holiday camps and private houses and apartments for rent. The larger businesses are based in the town of Anapa, and the town is a key focus for tourist activity and accommodation within the municipal district and has a high number of hotels, restaurants and associated infrastructure to support the tourism economy. Smaller-scale facilities are more commonly found in the surrounding communities, including in particular within Sukko (Ref. 14.21). Sukko is the main focus for tourism activity amongst the Local Communities due to its location on the coast behind Sukko beach and its therefore well-developed tourist infrastructure and services including recreation centres, fishing and horse riding facilities. The population of Sukko expands to approximately 12,000 during the peak of the tourist season from July to August (Ref. 14.27).

Information gathered during interviews indicates that Varvarovka and Gai Kodzor do not have commercial holiday accommodation or recreational facilities, nor do local families within these two communities rent out their premises to tourists, as neither community is easily accessible to the seaside (Ref. 14.17 and Ref. 14.25). The population of Supsekh increases by approximately 1,000 during the tourist season; however, this reportedly consists mostly of temporary workers employed in tourism services in the ART who stay there while working in tourism services in the Anapa Resort Town and particularly the town of Anapa itself. Similarly, a small number of people (precise numbers are not known) are also understood to lodge in Varvarovka (Ref. 14.17).

Chapter 17 Ecosystem Services presents information in relation to the municipal district’s designation as a health resort town in 1957. As a result, health resort complexes are critical to the area’s appeal as a tourism destination and there are apparently in excess of 150 health resort institutions (including 44 recreation facilities for children), approximately 250 hotels, and more than 2,000 vacation rental properties in the sector (Ref. 17.15).

Tourism, Accommodation and Recreation Facilities

Figure 14.12 shows the public, social and recreational infrastructure within and near to the Local Communities surrounding the Project.

In the ART municipal district, the number of beds available in tourist accommodation facilities rose by 62% over the five years to 2011 to a total of 162,000 beds, an indicator of the growth of the tourism sector in ART. The majority of this growth occurred in hotels, where the number of beds approximately doubled. There are many (approximately 200) large-scale facilities including sanatoria, holiday camps and children's camps (the majority of which operate in the summer season only). There are approximately 350 smaller businesses (i.e. up to 50 rooms), as well as more than 4,000 small private accommodation rentals such as houses, apartments or single rooms (Ref. 14.21).

Tourist accommodation facilities in Sukko include over 300 hotels; seven health resorts, sanatoria and health improvement centres; and three children’s and tourist camps (Ref. 14.17). During a field visit to the area in August 2012 at the height of the tourist season, it was
observed that local residents of Sukko also appear to rent out rooms to visitors; which is likely to help supplement livelihoods for those households.

**Hiking**

Varvarovka, Sukko and Supsekh are part of the "Mountains of the Caucasus" tourist hiking route. The route begins in Supsekh, bypasses Varvarovka (running over the cliff top and hill that the microtunnel will pass underneath) and passes through Sukko to the Bolshoi Utrish SPNA, where a waterfall is the final destination (Ref. 14.56).

**Local Beaches**

Sukko has a public beach that is easily accessible (Figure 14.15). It is the principal and only easily accessible public beach between the town of Anapa and the Utrish SPNA and is popular with both tourists and the residents of the Local Communities. The beach is a focal point for a number of summer activities for residents and tourists alike, including swimming, sunbathing and family activities.

In addition to Sukko Beach, two other beaches have been identified in the Project Area:

- The beach in front of the Shingari Holiday Complex is mostly used by guests of the Shingari and Don holiday complexes (Section 14.4.3.3), as well as a few local residents or tourists. This beach is accessible by steps from Shingari, and via a path that runs along the outside edge of the Shingari Holiday Resort grounds; this path is used by guests staying at Don to access the beach. This beach and the Shingari Holiday Complex are shown below in Figure 14.16; and

- Adjoining the Shingari Holiday Complex's beach is a natural beach in the Varvarovka Rift. This beach is located more than a kilometre from the nearest road. Although it is a public beach, it is not widely used as it can be reached only on foot. It is used infrequently by local residents.
Figure 14.15 Beach in Sukko (Showing Views to Sea and Inland from Northern End of Beach)
Figure 14.16 Shingari Resort and View of the Beach from the Resort
14.5.10.2 Tourist and Recreation Activities

**Land-Based Activities**

There are approximately 40 companies that organise excursions and other activities for tourists in the ART municipal district. Facilities include diving, yachting and horse riding (Ref. 14.21). There are also tourist attractions such as a dolphin park and an "African village", both in the town of Anapa, and the Bolshoi Utrish nature reserve south of the town of Anapa (Ref 14.27).

Horse riding takes place in and around the Local Communities, including around Sukko, Supsekh (Ref. 14.57 and Ref. 14.58) and around Varvarovka (Ref. 14.56 and Ref. 14.59). There is a business based in Varvarovka, with approximately 30 horses, that offers horse riding tours for both adults and children on at least three different routes (depending on the abilities of the rider) including a route used for novice riders that traverses the Agrifirm Kavkaz fields in the direction of a lake north of Sukko. The business is at its busiest during the summer, when it has approximately 20 customers per day, although the business will operate during winter if there is customer demand; weather conditions permitting. In the summer, it is understood that horse riding in Sukko and Varvarovka is generally more popular with holiday makers.

The horse riding route that traverses Agrifirm Kavkaz land is used for novice riders and children, who make up the majority of the clients for the business. It is possible that the route through the Agrifirm Kavkaz fields may cross areas that may be affected by Project construction activities. South Stream Transport has met with the operator of this business to discuss the Project and potential overlap with horse riding routes; however, at this time, the operator was unable to identify the precise routes and further discussions are planned (Ref. 14.59).

**Chapter 16 Cultural Heritage** confirms that among local monuments, there is extensive tourist interest in Krasnodar’s Bronze Age dolmens, some of which are subject to tourist pilgrimages and offerings (Ref. 16.109). Internal tourism is also linked to local festivities and cultural heritage sites. There is a spring in northern Varvarovka, known as St. Barbara’s Source, and an annual procession takes place on the Feast of Theophany (Epiphany / Feast of Lights / Feast of the Manifestation, 19 January). Attendees include local parishioners and pilgrims from further afield (Ref. 16.114; Ref. 16.115). Further information on cultural heritage sites, and intangible cultural heritage such as local celebrations and festivals, is presented in Chapter 16 Cultural Heritage.

**Water-Based Activities and Attractions**

In addition to recreational activities such as swimming and fishing, the coast is also used occasionally for activities including paragliding, jet skiing and diving.

There is a sunken barge named Gordipiya located near the mouth of the Sukko River (location coordinates N 44°46' E 37°22''), which is a locally known dive site. The wreck itself is in relatively poor condition, as most things of value and interest have been looted from the site, although a field observation in summer 2013 indicated that it is a relatively popular local diving attraction.

Figure 14.18 shows that the location of the wreck is outside of the proposed 3 km marine safety exclusion zone during construction.
In Sukko, special recreational programmes for children are operated by the children’s health improvement camps, such as ‘Energetik’ and ‘Smena’. These recreational programmes include trips out to sea on motorboats, diving, and trail walking (Ref. 14.60). Paragliding was also observed to be taking place from a hill in Sukko (south from the landfall section of the Project) with the flying trajectory being out to sea. Paragliding is understood to be an informal recreational activity rather than a business (Ref. 14.57). Information about the identity of the people and groups paragliding is not known (Ref. 14.17); however, it is likely that at least some of the activity is engaged in by tourists visiting the area.

Figure 14.17 The Bow of the Sunken Barge 'Gordipiya'
14.5.11 Fisheries

14.5.11.1 Industry Overview

Over the past 40 to 50 years, there have been important changes in the Russian Black Sea fishery. For example, annual Soviet Union Black Sea catches reached a maximum in the mid-1970s to mid-1980s, averaging 65,000 to 68,000 tonnes (t) (this included catches from Black Sea ports that are no longer in the Russian Federation since the break-up of the Soviet Union). However, a combination of factors such as pollution, the effects of invasive species, expanding coastal development, and the deterioration of the fishing fleet, onshore infrastructure and facilities following the break-up of the Soviet Union, have resulted in a reduced fishing industry and catch volumes (Ref. 14.61). The Russian catch in 2003 was 21,000t, which is a notable increase from a low point of approximately 700t in the 1990s. This rapid increase was predominately due to the introduction of new trawling technology. Catch has subsequently declined and in 2012 had fallen to just under 4,000t, around a fifth of the Total Allowable Catch (TAC) of 21,000t (Ref. 14.61). The species composition of the catch has also altered due to the environmental changes in the latter 30 years of the 20th century (Ref. 14.62) (refer to Chapter 12 Marine Ecology for more information on the historical ecological changes to the Black Sea).

14.5.11.2 Fisheries within the Project Area

An analysis of the fisheries within the Study Area of the Project has been completed, including information on fishing fleets and companies that fish within the Project Area, catch levels and types, as well as commercially important fish stocks and their migration routes (see Appendix 14.1).

Fishing Areas

There are two main fishing areas recognised by the Azov Research Institute of Fisheries: (i) the Kerch-Taman zone, the more northerly zone that extends along the coast from the Kerch Strait to Cape Utrish; and (ii) the Caucasus zone, the more southerly zone that stretches from Cape Utrish south to the mouth of the Psou River, near the border with Georgia. The Kerch-Taman zone encompasses the entire nearshore section of the Project Area (Ref. 14.61). The Caucasus zone, which is predominantly fished by vessels south east of Cape Utrish, overlaps with part of the offshore section. These zones are approximately equal in area, but different in biological resources. Of the two zones, the most productive is the Kerch-Taman zone.

The main fishing ports are the town of Anapa in the Kersh-Taman zone and Novorossiysk (the largest) and Gelendzhik in the Caucasus zone. Russian Black Sea fishing activity is limited to internal and territorial waters of Russia, within 12 NM of the coast (Ref. 14.61).

Within the Kerch-Taman zone, there is an area known as the ‘Anapskaya Bank’ or ‘Anapa Bank’ which is designated²⁶ as an important fishing ground. GIS analysis indicates that the Anapa Bank is approximately 695 km² of which the Project Area accounts for around 0.6%. Fishing is seasonally restricted, trawl fishing and fishing with stationary nets with a cell size of more than 50 mm is forbidden. Since 2011, sections of the Anapa Bank area have been made available for sprat and anchovy trawling under the Russian Fishery Regulations (Ref. 14.61; and Ref. 14.63). The regulations state:

- Bottom trawling (using any gear) is prohibited over the Anapa bank, in waters less than 40 m;
- Fishing for sprat is permitted between July and September annually in water depths of more than 40 m; and
- Fishing for anchovy is permitted from the beginning of October until the 15 March annually at water depths of more than 20 m.

More information on the Anapa Bank common fish species, fishing activity and fishing restrictions is provided in Chapter 12 Marine Ecology and Appendix 14.1.

There are also a number of fixed traps and nets in place close to the coast to target migrating fish such as mullet, they are normally serviced by smaller vessels (<5 m). There is also a mussel farm approximately 4 km to the south, currently producing around 15 tonnes of mussels on an annual basis (see Appendix 14.1).

**Fishing Fleet**

The Fisheries Study (Appendix 14.1) has found that the Russian fisheries industry in the zone of influence is relatively small; e.g. in Krasnodar Krai it contributed 0.1% of regional GDP in 2009¹⁴²⁰. The study has further identified that the importance of fishing in the region has declined in recent decades, partly due to the invasion of the predatory comb jelly *Mnemiopsis leidyi* and the consequent ecosystem-wide changes affecting most of the Black Sea, and also in part due to the demise of the USSR.

The majority of the vessels use pelagic or surface gears to catch anchovy. The most common are purse seines²⁷ which are permitted within the entire Russian Black Sea territorial waters. Trawl nets are also commonly used although only midwater trawling is permitted; the nets must not come into contact with the seabed. There is no pair trawling recorded in the Russian sector of the Black Sea. Some vessels are also equipped to use passive gear, either as their primary or secondary gear type. This will normally consist of a fixed bottom net and will be used to target bottom species such as turbot and rays (Ref. 14.64, Ref. 14.65 and Ref. 14.66).

---
²⁶ The Anapskaya Bank was initially designated in 1986 by Decree of the Ministry of Fisheries of the USSR. The area where fishing was prohibited was reduced by the Resolution of the Scientific Fishery Council of the Azov and Black Sea Basin in 1999. In 2011 the fishing ban was further reduced and it now merely consists of seasonal restrictions to enable the replenishment of fish stock.
²⁷ A purse seine is a very long net, which falls as a curtain from a floating head rope, that is use to surround shoals of open water fish. After encirclement, the bottom rope is pulled tight to trap the fish in the ‘purse’. It never comes into contact with the sea bed.
Accordingly, both the size of the fleet and the number of companies active in the Russian Black Sea has declined. For example, the number of enterprises involved in capture fishing and located in the northern half of Krasnodar Krai’s Black Sea coastline\textsuperscript{28} has declined from 19 in the period between 2003 and 2006 to 14 in the period between 2007 and 2010. The decline in the number of enterprises has been accompanied by a decline in the number of operating vessels from 30 to 21 over the same period (Ref. 14.61).

In addition to the decline in the number of vessels and companies, the condition of fishing fleet vessels and onshore reception and processing facilities has suffered from underinvestment and the vessels and onshore facilities are generally old and have not been renovated or replaced by modern equipment. The lack of investment is due to the poor financial state of the fisheries sector since the early 1990s. However, catches have been higher in past years compared to the 1990s (Ref. 14.66).

**Commercially Important Species**

Anchovy (\textit{Engraulis encrasicolus}) and sprat (\textit{Sprattus sprattus}) are the most important species in the fishery, comprising 28% and 25% of the Russian Black Sea catch respectively; red mullet (16%) and whiting (12%) are also significant. Anchovy spawns in the Sea of Azov in the summer months and migrates to the Russian and Georgian shores of the Black Sea as waters cool until the following spring. Thus, in the Black Sea territorial waters of Russia, anchovy form commercial concentrations during the cold season from October to April. Commercially exploitable populations of sprat are found in Russian Black Sea coastal waters from April until September (Ref. 14.61).

From data collected by the Project during meetings with the Zao Moresky Club, Bolshoy Utrish; as of 2013, the commercial species with the highest value per tonnage caught were farmed mussels and turbot which were valued at 300,000 RUB (approximately £5,000). Mullets were 100,000 to 150,000 RUB (approximately £1,600 to 2,500), and horse mackerel, piked dogfish, thornback rays and pontiac shad were valued between 30,000 and 40,000 RUB (approximately £500 to £620) (Ref. 14.4).

Research into fish stocks has found that species diversity declines with depth. For example, a study in 2010 recorded 64 distinct species at depths of less than 25 m (i.e. the continental shelf), whereas in deeper water (50 to 85 m) only eight species were recorded. This finding reflects the known wider characteristics of the Black Sea where the nearshore areas are species-rich in comparison to the deeper offshore waters (see Chapter 12 Marine Ecology).

The concentration of Russian Black Sea fishing activity and effort reflects this species gradient, as most commercial fishing occurs in nearshore waters out to a depth of approximately 100 m.

\textsuperscript{28} This includes the stretch of coastline between the Kerch Strait and Arkhipo-Osipovka, a town located at the approximate mid-point of Russia’s (and Krasnodar Krai’s) Black Sea coastline. This stretch of coastline includes the town of Anapa and the ports at Novorossiysk and Gelendzhik (which are over 50 km and 80 km from the location of the microtunnel exit pits) respectively.
14.5.11.3 Fishers Operating in the Project Area

The nearshore section of the Project Area is located within the Kerch Taman zone encompassing the Anapa Resort Town (ART) municipal district.

As set out in Table 14.7, there are approximately 1,000 people working in the fisheries industry in the ART Municipal District. The number of people employed in the fishing industry along the northern half of the Russian Black Sea coastline as a whole is relatively small consisting of two large companies employing up to 100 people, three medium-sized companies employing up to approximately 30 fishermen in the case of the largest company and nine smaller companies (typically comprising a few smaller vessels and fishing brigades using passive gear such as set nets and traps) which may have only as many as 15 employees (see Appendix 14.1).

In order to collect data regarding the companies and their owners and employees, invitations were sent to all fishing companies that are known to fish in the marine Project Area, i.e. in the Anapa municipal district. Of the five companies invited to participate in an interview, three responded positively:

- OOO RAM, Anapa;
- RPK Briz, Anapa; and
- Zao Morskoy Club, Anapa.

Meetings took place in March, August and October 2013 and the data obtained from the interviews is provided below.

RPK Briz Fishing Company

RPK Briz Fishing Company has an office in Varvarovka and stated that they are one of approximately eight companies that are located between the Temryuk area and Novorossiysk, which operate in the area where the Pipeline will be constructed. The company has been operating since 1998 and employs approximately 30 people. They operate one vessel (17 m) in deeper waters and three smaller vessels in coastal waters. The offshore vessel is a bottom trawler and uses both trawl gear and fixed nets. As bottom trawling is banned, the gear used is for trawling in the mid-water, from around 40 m to a maximum depth of 100 m. This vessel also uses fixed nets further offshore.

The majority of their catch is anchovy, with other significant catches including sprat and red mullet. The company previously owned three vessels but this was reduced to one. Traps are used in the nearshore area and all fish caught is processed (smoking, salting, freezing) onsite.

The fishing grounds used by RPK Briz Fishing Company extend from the Strait of Kerch southwards to Sochi, depending on where the fish are. The fixed traps are located between Mali and Bolshoi Utrish. Some fishing is carried out along the proposed Pipeline route (Ref. 14.2).

OOO RAM Fishing Company

OOO RAM Fishing Company, with an office in the town of Anapa, has been operating since 1996 and employs 15 people. The company owns three vessels and leases two (ranging from 4.5 to 15 m). The smaller vessels are used for nearshore nets and the larger vessels are trawlers that
trawl in the mid-water depth as bottom trawling is banned. The main species caught is anchovy, as well as sprat and red mullet. Previously, sprat was the main species caught, but the company indicated that stocks of sprat have declined since 2008. The fish are processed onsite and then sold onto wholesalers regionally and nationally. Fishing also takes place along the coastal area (Ref. 14.3).

ZAO Morskoy Club

ZAO Morskoy Club, based at Utrish, has been operating for nine years and was previously a fishing cooperative. There are 15 fishermen working from the club, for whom the work is their only source of income. In addition to the fishery there is also a small marina with approximately 100 vessels, directly employing between 15 and 50 staff within the marina (yacht repair, etc.) in addition to the captains and crew employed by the owners of the vessels. They operate seven vessels (one 15 m vessel and six 9 m vessels), all of which are over seven years old.

The majority of their catch is red mullet, while other significant species caught include horse mackerel, turbot, piked dogfish and flathead mullet. The fish are caught in traps as they migrate and the high season runs from May to the end of November. They operate five different types of traps, including nearshore and floating (offshore) traps, within a designated and permitted area. The traps remain in the same positions every year, as the migration path of the fish is the same every year. The company’s designated permitted area extends between the Sukko River to the lighthouse in Bolshoi Utrish, and no further than 5 km from the shore. Fish are not processed on site but are loaded onto trucks and sold wholesale.

Since 2006, the Club has also owned and operated a mussel farm. Mussels are harvested all year and are sold to a wholesaler in Moscow. The company indicated that there is no bottom trawling off the coast of the ART municipal district as this activity is banned (i.e. within the waters of the Anapa Bank up to 40 m water depth). The company does not consider that fish catches have changed over the past nine years (Ref. 14.4).

14.5.12 Vulnerable Groups

14.5.12.1 Identification of Potentially Vulnerable Groups

IFC PS 1 on Assessment and Management of Environmental and Social Risks states that it is necessary to identify individuals and groups that may be differentially or disproportionately affected by the Project because of their disadvantaged or vulnerable status. Individual or group vulnerability is a pre-existing characteristic that is independent of the Project and may be reflected by factors such as disability, language, culture, gender, and social status. It may also be exhibited by a low level of access to key socio-economic, social or environmental resources or a limited ability to adapt to change. Therefore, vulnerable individuals and groups may be more susceptible to adverse impacts or have a more limited ability to take advantage of beneficial impacts.

Vulnerability is also an important factor in stakeholder engagement as certain groups of people may have less access to information and decision-making processes. For example, low income households may not have access to computers and internet sources, and may have difficulty travelling to consultations.
Using this guidance and in collaboration with two social protection bodies in Supsekh and Gai-Kodzor and the Anapa Resort Town Municipal District administration, potentially disadvantaged or vulnerable groups have been identified in the Local Communities. These are: children; elderly or retired people; disabled or chronically ill people; migrants involved in seasonal work; households with incomes below the subsistence level, and commercial sex workers.

Although there are significant numbers of non-Russians in the ART municipal district, particularly Armenians (but also Ukrainians, Uzbeks and others), evidence from the socio-economic baseline study indicates that they are integrated into the socio-economic and socio-political life of the area, even though they may maintain specific cultural practices (Ref. 14.27 and Ref. 14.33). These minorities are not, therefore, considered to be vulnerable for the purposes of this assessment.

The six groups are described below in relation to their potential vulnerability and their presence in the Local Communities. This analysis considers both the potential for differential or disproportionate impacts of the Project, and potential vulnerabilities in terms of stakeholder engagement (including access to information and participation in decision-making processes). It is important to note that vulnerability is described in the context of the Project, although these groups may also be challenged by other aspects of vulnerability.

The sensitivity or vulnerability of these groups has been considered, where relevant, in the assessment of potential socio-economic impacts in Section 14.6. Other assessments (e.g. Chapter 15 Community Health, Safety and Security) have also considered the vulnerability of these groups. With respect to stakeholder engagement, these groups (and their limitations) have been, and continue to be, considered in the planning of stakeholder engagement activities, including the disclosure of information and the locations of and access to consultation events. Further details are provided in Chapter 6 Stakeholder Engagement.

**Children**

Children, especially those below the age of 15, may be specifically vulnerable to impacts related to changes in environmental conditions; children are generally considered to be more sensitive in comparison to adults, particularly with regard to effects on their learning capabilities related to noise from sources such as road traffic (Ref. 14.67) and to effects on health arising from air pollution (Ref. 14.68) (Chapter 9 Air Quality notes that very young children are more likely to be adversely affected by changes in air quality than adults). School age children are also particularly vulnerable as pedestrians to increased levels of traffic and impacts on traffic safety, for example when walking to and from school, especially if unaccompanied by an adult. The interests of children may not always be represented in stakeholder engagement and decision making processes.

Children are present in all of the Local Communities within the Study Area, although precise information on the number of children within each Local Community is not available. However, children are likely to be concentrated in and around kindergartens and schools, as well as community centres and recreational or leisure facilities such as children’s holiday camps. If any kindergartens and schools are located on or near to roads that will be used by construction traffic, then children attending those schools may be at increased risk of exposure to potential traffic safety dangers.
Elderly

Elderly people may be challenged to cope with changes in the surrounding environment as a result of deteriorating physical and/or mental capacity. For example, Chapter 9 Air Quality notes that, in general the elderly are more likely to be adversely affected by changes in air quality than middle aged adults. These challenges may also affect the ability of elderly residents to participate in consultation and decision-making processes, not least in terms of physical accessibility to consultation venues, and a typically lower use of computer-based media.

Additionally, elderly or retired people are also likely to be more constrained financially, due to the prevalence of fixed incomes. However, since 2009, the average pension in the ART municipal district has exceeded the official subsistence level (Ref. 14.15). This coincides with an official increase in the state pension designed to improve the economic wellbeing of pensioners across Russia.

Within the Study Area, elderly residents29 in the Local Communities of Varvarovka, Supsekh and Sukko account for between 15 and 19% of the population depending on the community (equating to over approximately 300, 1,600 and 600 people respectively) (Ref. 14.17).

Disabled or Chronically Ill

Disabled or chronically ill people, which may include individuals who lack physical mobility or who have mental health issues, may experience difficulties participating in consultation processes and decision making.

Data on the number of disabled or chronically ill people within the Local Communities was not available, with the exception of Rassvet and Gai Kodzor (both located within the Gai Kodzor Rural District Administration). The Gai Kodzor Rural District Administration reports that there are approximately 500 people (out of total population of approximately 6,000) living with some kind of disability in the district (Ref. 14.18).

Migrant Workers

Seasonal migrant workers, particularly those working on a seasonal basis in the agricultural or tourism sectors, are generally likely to have lower incomes and less access to resources. They may also have lower levels of resilience to unexpected events, depending on their personal circumstances including in their home communities. In particular, they may be sensitive to a loss or reduction in employment opportunities. As non-residents, their interests may not be represented in local decision making, and it may be difficult to engage these groups due to the seasonal (and often unofficial) employment status.

Seasonal migrant workers in the Study Area include workers from Dagestan who are employed on an annual basis by Agrifirm Kavkaz to work in the vineyards (Ref. 14.40). Seasonal migrant workers are also employed generally within the tourism sector in Anapa Resort Town (Ref. 14.24; Ref. 14.39). However, this will not be true of all companies in the tourism sector,

29 Defined by the relevant local rural district administration as women aged over 55 and men aged over 60.
e.g. Shingari Holiday Complex reports that most of its seasonal employees during the peak tourism season are drawn from the local area, including the town of Anapa (Ref. 14.19).

Low Income Households

Low income households have fewer financial resources to rely on and are less likely to have savings and/or access to credit, which in turn can make them vulnerable to environmental changes and economic fluctuations. They may also face limitations to accessing information, for example due to limited access to computers and/or the internet, limited transportation options, and financial or time constraints that limit their ability to actively engage in stakeholder consultation. This group is likely to include households with pensioners, unemployed (or underemployed) persons, and people employed seasonally or in low-income occupations. It may also include households with children, seasonal migrant workers and disabled or chronically ill people.

In the Local Communities, low income households are likely to include pensioners and unemployed persons. It may also include households with children; persons employed part time, seasonally or in low income occupations; seasonal migrant workers (see above) and disabled / chronically ill people. People working in the fishing industry (particularly artisanal or small-scale operations) may also have low or variable (and unreliable) incomes.

Commercial Sex Workers

In the context of major construction or resource development projects, commercial sex workers are often vulnerable to the transmission of communicable diseases, including sexually transmitted diseases, particularly from migrant workers if they engage in unprotected sex. They are also likely to have low or unreliable incomes and may have limited social networks and resilience to cope with change. Additionally, people who are deprived, suffer from drug or alcohol addiction and/or suffer from mental illness are particularly susceptible to sexual exploitation.

Precise numbers of commercial sex workers in the Local Communities is unknown; baseline studies, including information from local authorities, have indicated that prostitution is not an issue in this family-focused resort area. However, as noted in Chapter 15 Community Health, Safety and Security relatively high numbers of commercial sex workers would not unexpected for the port towns, or in communities spanning or close to major roads such as the M25. Additionally, Chapter 15 has identified that there are relatively high levels of syphilis observed in the ART municipal district that may be due to, amongst a number of other factors, to the presence of commercial sex activities.

14.5.12.2 Stakeholder Engagement with Vulnerable Groups

Stakeholder engagement in Russia began in 2010, when consultation was held in the Krasnodar region, including the town of Anapa, in relation to the Preliminary EIA (during the Feasibility Phase). Since then, South Stream Transport has carried out consultation in relation to both the EIA and the ESIA.

Stakeholder engagement efforts have been adjusted to ensure the participation of vulnerable groups as far as possible, and to ensure access to engagement and consultation methods.
Representatives from local education and health care facilities, local pensioners associations and representatives of community centres for local youth groups and school directors (inviting local youth to participate) were directly invited to public consultation sessions during the Scoping Report engagement stage. Efforts have also been made to disclose information in a variety of ways so as to be accessible to all groups. For example, printed copies of reports have been provided in central community locations, as well as electronic copies on the internet; announcements have been made in local newspapers, and through posters in local shops, bus stops, and other community locations; information has been hand-delivered to schools and pensioner groups; and open meetings have been held in potentially affected Local Communities.

For further information on engagement with stakeholders and vulnerable groups see Chapter 6 Stakeholder Engagement.

14.5.13 Baseline Summary and Key Findings

This section provides a summary of key findings and observations arising from the preceding baseline in respect of the ART municipal district and each of the five Local Communities.

14.5.13.1 The Anapa Resort Town Municipal District

The main observations arising from the baseline in relation to the ART municipal district are as follows:

- The ART municipal district includes the Local Communities of the town of Anapa, Gai Kodzor, Rassvet, Supsekh, Sukko and Varvarovka;
- The ART municipal district is a designated ‘resort town’ which provides for a regime of measures intended to safeguard the district’s important tourism attraction features;
- Tourism is the most important industry in the ART municipal district and visitor numbers and accommodation facilities have displayed continuing strong growth over recent years;
- The municipal district has experienced rapid growth in population over the last few years (ca. 9%) compared to the wider Krasnodar Krai region and the Russian Federation;
- The municipal district’s strong population growth rate has been driven by high birth rates, lower death rates and higher net in-migration, as well as it’s relatively strong economy;
- Armenians and Ukrainians make up the largest minority ethnic groups. Uzbeks are emerging as another minority ethnic group and there is evidence pointing to their importance as workers (seasonal and permanent) in the tourism and construction sectors;
- The ART municipal district administration estimates that the two leading economic sectors are the tourism sector and the retail and services sector. Agriculture is estimated to account for 3% to 5% of economic activity within the municipal district, while the fisheries sector is estimated to accounts for less than 1%;
- The growth in population and the tourism sector appears to have been associated with and/or led to changes in a number of other socio-economic indicators; and
- Overall, growth in a number of different indicators points to changing social conditions and economic growth in the district that appears to be driven by the growth of tourism.
14.5.13.2 The Local Communities

A summary of key findings and observations is provided for each Local Community (in alphabetical order).

Town of Anapa:
- Has the largest population of any community in the municipal district, accounting for approximately 40% of the ART municipal district’s residential population;
- Is the centre of tourist activity and accommodation within the municipal district and has a large number of hotels, restaurants and associated infrastructure to support the tourism economy;
- Is the primary hub in the municipal district for services and facilities. The town’s social infrastructure is more developed than that of the surrounding rural communities within ART municipal district. All households have mains water and gas supply; and
- Is also an employment hub for many residents of the nearby rural communities.

Gai Kodzor:
- Is located 3 km north-east of the Project Area and 4 km north-east of the Project landfall facilities;
- Is a relatively small community of approximately 3,370 residents;
- Has an approximately 70% Armenian population, a much higher proportion than average in the ART area;
- Has an Armenian community centre, a school, and various shops, located along the main road running through the community; and
- Has relatively good utility provision compared with the other Local Communities. Most households have mains water and 75% of the community is supplied with gas.

Rassvet:
- Is located approximately 4 km north of Gai Kodzor, on the construction access route from the ports;
- Is a small community of approximately 1,400 residents;
- Is flanked on the north by route M25, and adjoined to two other smaller separate communities; one to the west (Tarusin) and to the east (Zarya);
- Falls within the Gai Kodzor Rural District Administration area;
- Nearly 60% of Rassvet population is Armenian, 40% is Russian; and
- Rassvet community does not have a disproportionate number of any of the vulnerable groups: children, elderly, disabled, etc.

Sukko:
- Is located approximately 3 km to the south east of the Project Area, with a small part of the community located within 2 km of the Project;
• Is the only rural district Local Community that is located on the coast, and the Sukko beach is a well-known tourist and public recreational facility in the area;
• Is also bordered to the south by the Utrish SPNA;
• Is the focus of tourism in the Local Communities due to its beach and well-developed tourist infrastructure and services; and
• Has poor utilities provision relative to the other Local Communities, with only 50% of households being supplied with piped water and only 10% being connected to public sewers. Further, no households in Sukko have piped gas.

Supsekh:
• Is located more than 4 km to the north of the landfall section construction site;
• It has a population of approximately 8,760 people and accounts for approximately 6.0% of the population of the ART municipal district;
• Is located close to the town of Anapa and a large proportion of its employed residents work within the town of Anapa;
• Has more developed utilities infrastructure than the other Local Communities: all households have mains water and gas;
• Is not a centre for tourism accommodation although some seasonal workers do reside here during the peak tourism season; and
• Is viewed as a desirable place to live on account of its well-developed infrastructure and proximity to Anapa town, reflected in local house prices.

Varvarovka:
• Is the Local Community located closest to the Project Area;
• Is a relatively small community of approximately 2,300 residents;
• Is not a centre for tourism accommodation although it is used as a base by seasonal workers as accommodation is relatively cheap compared with the town of Anapa;
• Has relatively poor utility provision compared with the other Local Communities, for example, no households in the community are connected to the public sewer system or have piped gas;
• Increases only slightly in population during the tourist season: by an estimated 150 people, comprised of seasonal migrants who stay in the community while working in the ART area;
• Is home to the Kavkaz Winery, a grape producer and wine maker that owns some 80% of the land that will be affected by the Project; and
• Is also the headquarters for Briz, one of two small commercial fishing organisations in the Anapa Resort Town municipal district.
14.6 Impact Assessment

This section identifies and assesses the potential impacts on the existing socio-economic environment arising from Project-related activities. Information within Chapter 5 Project Description and the baseline socio-economic characteristics (Section 14.4) have been used to assist the evaluation of the potential impacts and their significance.

14.6.1 Impact Assessment Methodology

This chapter examines the impacts associated with the Project, including economic, community, Project workforce and transportation-related impacts. The methodology specific to socio-economics presented in this section builds upon the general assessment methodology summarised in Chapter 3 Impact Assessment Methodology. The methodology has been adjusted specifically in relation to effects on socio-economics arising from the construction and operation of the Project. The Project components and activities for each phase, as relevant to the assessment of socio-economic impacts, are summarised in Section 14.6.1.1. The criteria for the assessment (magnitude and receptor sensitivity) are defined in Section 14.5.1.2, and notes on the methods applied in the assessment are described in Section 0.

14.6.1.1 Project Activities

The Project Description is presented in Chapter 5 Project Description. The elements of the Project that are relevant to socio-economics are set out below.

Construction and Pre-Commissioning Phase

Construction of the Project will create employment opportunities and also increase demand for goods and services from construction, port services, and other sectors. However, the majority of the employment opportunities created by the Project will require highly specialised skilled labour, and it is anticipated that these jobs will be filled by the Contractors’ existing workforce or specialised sub-contractors from outside the local area. As such, the workforce is expected to consist primarily of non-local workers. Workers employed on the marine sections of the Pipeline (offshore and nearshore) will be accommodated on the construction vessels, whilst workers on the landfall section are likely to be lodged in nearby towns and villages.

Construction of the landfall section including the landfall facilities, pipeline corridor, microtunnels, and temporary and permanent access roads will also require both temporary and permanent land access and/or acquisition. Affected land includes areas currently characterised as forest and vineyard. During construction, access to the construction corridor will be restricted for safety reasons.

Construction of the nearshore and offshore sections of the Project will be based from the pipe-lay barge, supported by a number of other vessels. A safety exclusion zone will be established around the construction vessel spread; this zone is expected to extend 3 km up to 600 mbsl from the pipe-laying barge and 2 km beyond that depth, wherein vessels and activities not related to Project will be restricted.
Roads within or near to the existing Local Communities – including Varvarovka, Rassvet and Gai Kodzor – will be used as access routes for construction traffic to transport equipment and materials to and from the landfall construction site. A bypass road will be constructed along the north eastern side of Varvarovka as part of the Project and used by construction traffic to avoid construction vehicles travelling though the centre of Varvarovka during the Construction and Pre-Commissioning Phase. Also a part of the Project, consisting of a temporary access road, will be constructed a short distance to the east of the Varvarovka village cemetery.

Although it is anticipated that there will be no marshalling yards located on the Russian coast, it is likely that the contractor will use the Port of Novorossiysk for some of the activities listed below during the Construction Phase of the Project, including: temporary storage of pipe and other plant, equipment and supplies; load out of pipe to the landfall section via road transport; as a base for supply vessels; re-fuelling and maintenance of construction vessels; and as a base for crew-change vessels travelling to the nearshore and offshore construction spread.

Construction-related activities on land and at sea, including road traffic and marine vessel movements, could result in amenity effects (e.g. changes in air quality, dust, noise, vibration, water quality, and changes to views) which may be noticeable to people in the area and affect the quality of the surrounding environment as they experience it, including residents of Varvarovka and Rassvet, the Shingari and Don holiday complex businesses, as well as people visiting the broader Anapa Resort Town municipal district for the purposes of tourism and recreation.

Construction works within the landfall section of the Project are expected to last 27 to 30 months. Works within the nearshore section will overlap with the latter period of the landfall section construction and are expected to last for approximately 15 months, and the majority of the construction works within the offshore section are expected to last for approximately 30 months or 2.5 years. For further detail on the construction schedule see Chapter 5 Project Description.

Operational Phase

Once constructed, the landfall facilities will remain for the duration of the Operational Phase and will comprise the landfall facilities containing buildings and monitoring equipment. The construction corridor will be reinstated; the pipelines will be buried and the corridor will be revegetated. A permanent RoW will be in place; trees and other deep-rooting vegetation will not be permitted to grow within the RoW, but outside this area the land will be reinstated to its former uses.

Operational safety exclusion zones will also be established, and will place certain conditions on the use and development of land in relation to agriculture and construction within 410 m of the two outermost pipelines, although the area will still be accessible. At sea, a safety exclusion zone will also be established (500 m either side of the Pipeline) wherein seabed intrusive activities (e.g. bottom trawl fishing) will be prohibited.

Relevant Activities by Project Phase

For each Project activity, Table 14.10 indicates whether the activity has the potential to give rise to a socio-economic impact within the landfall, offshore or nearshore section of the Project. This
represents an initial screening of potential interactions; the potential impacts are further considered and described beginning in Section 14.5.2.

14.6.1.2 Socio-Economic Impact Assessment Criteria

Identification of Potential Receptors

Two broad categories of potential receptors that have been identified with respect to the potential socio-economic impacts of the Project are:

- Those that would be affected economically or financially (including workers, businesses, residents, landowners, land users, and users of utilities and telecommunications); and
- Individuals and groups within the local communities that could be affected either socially or in terms of their physical and mental well-being, or in terms of their recreational amenity.

Receptors and resources may vary by the type of impact, and different impacts may affect different receptors. A receptor may be an individual, household, group or organisation, or a community. Receptors may be affected by changes in the environment, or by changes to things such as land use, land ownership, transportation, livelihoods, incomes, community values, or the enjoyment of natural areas.

Accordingly, receptors which could experience a socio-economic impact in one or more of these ways as a result of the Project are identified and described in Table 14.11 which shows the key receptors in respect to economic and community related impacts.

### Receptor Sensitivity Criteria Tables

The concept of sensitivity attempts to reflect the degree of response to a change in baseline conditions by a receptor. This degree of response may range from being very susceptible to change (and having little resilience) to being able to absorb or adapt to change (being very resilient).

Within the socio-economic context, receptor sensitivity is difficult to define as it varies significantly within and between individual receptors for any given impact. The degree of sensitivity of a socio-economic receptor is based on an individual's abilities to adapt to changes and maintain their livelihood and well-being (i.e. resilience) and, in situations where an impact may result in a loss or reduction of access to a resource, their ability to access an alternative resource that provides the same service (e.g. a livelihood / employment, recreation, etc.). Sensitivity is not uniform. For example, not all fishing communities are equally vulnerable, and within a community, different individuals may have different levels of sensitivity. Sensitivity can also refer to 'vulnerability'.

In this assessment, sensitivity represents a stakeholder’s resilience or capacity to cope with change. There are a range of variables that can influence a stakeholder’s sensitivity and should be considered:

- Age, gender, race, religion;
- Land rights and ownership;
- Employment / unemployment / income;
- Livelihood strategies (and livelihood alternatives);
• Location / isolation;
• Public services, e.g. health access and quality;
• Access to, and use of, natural resources including water;
• Food security;
• Education / skills;
• Health or disability;
• Support networks; and
• Marginalisation (e.g. degree of access to services and formalised rights).

When considering impacts on people, sensitivity is typically a complex interaction of some or all such factors. In order to facilitate a comparison of impacts for the purposes of the ESIA, a series of criteria attempting to capture these elements have been established based on professional judgement and Good International Industry Practice. Table 14.12 outlines the criteria for evaluating sensitivity from negligible to high. The sensitivity of receptors will be considered in the context of each individual impact, although only certain criteria may be applicable depending on the type of receptor being assessed.

**Table 14.12 Socio-Economic Receptor Sensitivity**

<table>
<thead>
<tr>
<th>Sensitivity</th>
<th>Criteria</th>

</thead>
<tbody>
<tr>
<td>Negligible</td>
<td>A receptor with plentiful capacity and means to adapt to a given change and maintain / improve quality of life or that would not be affected in any material or noticeable way by a given change</td>
</tr>
<tr>
<td>Low</td>
<td>A receptor with some capacity and means to adapt to a given change and maintain / improve quality of life.</td>
</tr>
<tr>
<td>Moderate</td>
<td>A receptor with limited capacity and means to adapt to a given change and maintain / improve quality of life.</td>
</tr>
<tr>
<td>High</td>
<td>An already vulnerable receptor with very little capacity and means to adapt to a given change and maintain / improve quality of life.</td>
</tr>
</tbody>
</table>

**Magnitude of Impacts**

The magnitude of an impact is a measure of the degree of change in the baseline environment as a result of the Project. This baseline could refer to a diverse range of factors (i.e. financial, physical or emotional).

The dimensions affecting the magnitude of an impact are set out in *Chapter 3 Impact Assessment Methodology* and include the duration, frequency, reversibility and extent of an impact. The determination of impact magnitude for adverse impacts is also based on a scale of negligible, low, moderate and high.
Chapter 14 Socio-Economics

The quantification of impact magnitude (e.g. economic appraisals) depends on the availability of adequate data and is not readily applicable across all impact types. The criteria presented in Table 14.13 include a set of qualitative descriptions that characterise different levels of impact magnitude from negligible to high which reflect the dimensions set out in Chapter 3 Impact Assessment Methodology and which have been developed based on professional judgement and Good International Industry Practice. For beneficial impacts, the beneficial nature of the impact has been noted but the magnitude of the impact has not been assessed using the same scale; instead, a qualitative description of the benefit is provided.

It is also noted that impacts and outcomes associated with the Project may be either direct or indirect. However, these characteristics, while important to recognise and understand in terms of the application of mitigation measures, do not affect impact magnitude and are not directly considered in the socio-economic impact magnitude criteria.

Table 14.13 Socio-Economic Impact Magnitude

14.6.1.3 Impact Assessment Methods

Determining Impact Significance

The significance of potential adverse socio-economic impacts has been assessed by taking into account the magnitude of each impact (including their extent, duration, frequency and reversibility) along with the sensitivity of the relevant receptors, as outlined in Table 14.12 and Table 14.13. For beneficial impacts, the beneficial nature of the impact has been noted but the magnitude of the impact and the sensitivity of the receptor has not been explicitly identified, although the context of the potential benefit is discussed. As outlined in Chapter 3 Impact Assessment Methodology, the significance matrix provides basic guidance for the determination of impact significance; however, the resulting significance level is also checked against the descriptive definitions for each significance level (Not Significant, Low, Moderate, or High significance). The significance is interpreted on the basis of professional judgement and expertise, and adjusted if necessary.
Identifying Mitigation and Assessing Residual Impacts

As described in Chapter 4 Analysis of Alternatives and Chapter 5 Project Description, the Project design process has incorporated a number of design principles and measures to avoid or reduce adverse impacts. These are defined as design control measures. As a result, to the extent practicable, the Project design has minimised land acquisition, particularly land acquisition from good quality agricultural land. In the case of temporary facilities, the Project design has made maximum use of land likely to cause minimum economic displacement. This chapter has assessed impacts based on the Project design that has already incorporated these design control measures.

Within the respective impact assessment sections below for each phase of the Project, following the initial pre-mitigation impact assessment, a set of receptor-specific mitigation measures and other Project enhancement measures have been identified. These are explained in detail below.

Following assessment of the mitigation measures, the overall significance of the impacts, taking into account the mitigation measures, has been reassessed to arrive at the residual impact. The reassessment has applied the same methodology used to undertake the original pre-mitigation assessment.

14.6.2 Impact Assessment: Construction and Pre-Commissioning

This section identifies the potential socio-economic impacts and risks associated with the Construction and Pre-Commissioning Phase. For those effects where potentially significant pre-mitigation impacts are assessed in Section 14.5.2.1, potential mitigation measures have been identified in Section 14.5.2.2. This is followed by a residual impact assessment, the results of which are set out in Section 14.5.2.3. There are several potential impacts that were ‘scoped out’ and therefore not assessed for the Construction and Pre-Commissioning Phase and they are described below.

Impacts Considered and Scoped Out

The following potential socio-economic impacts were identified in relation to the Construction and Pre-Commissioning Phase of the Project. However, considering the Project description and the understanding of the baseline socio-economic characteristics presented in Section 14.4, the potential for these impacts to occur has been scoped out for the reasons described below.

Recreational Boating

It is considered that recreational boats (and other non-commercial vessels) will not be impacted by the Project given their ability to easily navigate around the vessel spread during construction of the nearshore and offshore sections. Information on restricted areas will be provided to the relevant authorities to inform navigation charts for marine stakeholders identifying marine exclusion zones through the Construction and Pre-Commissioning Phase.

Commercial Shipping

The Project Area is crossed by shipping routes, as set out in Appendix 9.1. However, due to the small area occupied by the construction spread (and the associated restrictions on navigation in
the vicinity of the construction spread, as described in Chapter 5 Project Description) and
the movement of the spread at approximately 2.5 km per day, it is expected that shipping
routes will not be affected as the pipe-laying spread can easily be avoided.

**Cliff Walking Trail**

Although Chapter 13 Landscape and Visual has assessed the potential for adverse visual
impacts for the cliff walking trail (also known as the "Mountains of the Caucasus Trail"), these
visual impacts will be temporary and short term and, given the way in which the trail is used, it
is not considered that these impacts would impair the use or enjoyment of the trail for
recreational purposes.

**Economic Displacement as a result of Land Acquisition**

To the extent practicable, the Project design has minimized land acquisition, particularly land
acquisition from good quality agricultural land. In the case of temporary facilities, the Project
design has made maximum use of land likely to cause minimum economic displacement.

However, land will still be required for permanent facilities (e.g. the landfall facilities and
permanent access roads) and will be leased from the owners for the lifetime of the Project.
Land to be used temporarily will be leased from the owners for the duration of the construction
activities. Two landowners are affected in this way: a privately owned land parcel is owned by
the Russian development company, Fond Yug, whereas the state-owned land is held by the
Russian Federal State Forestry Fund.

The Project will secure leases for the land required to construct and operate the Project by way
of negotiated settlement in accordance with South Stream Transport’s Land Acquisition Plan
(covering policy, approach and plan for land acquisition), which includes provision for leasing
land and which has been drafted in accordance with Russian legislation and the objectives of
IFC PS5, applying the higher of the two standards wherever they are not consistent. The Plan
provides for compensation based on a valuation mechanism conducted in accordance with the
objectives of IFC PS5 or national legal requirements, whichever is the greater.

There is no provision under Russian Federal law for compulsory purchase in Russia. As such,
South Stream Transports cannot expropriate land to make it available to the Project. South
Stream Transport must reach an agreement with land owners to acquire or temporarily use land
(e.g. by leasing) through negotiated settlement. Any financial impacts on the landowner
identified as part of the land acquisition process will be taken into account as part of the
negotiated settlement undertaken according to the Project Land Acquisition Plan and national
regulations. Further details on the approach to land acquisition for the Project can be found in
the Project Land Acquisition Plan, the principles of which are provided below:

- The Project avoids physical displacement and minimises economic displacement by
  routing and siting its facilities such that no residences are impacted by either direct
  footprint or buffer areas;
- The Project seeks to enter into negotiated settlements with affected landowners and
  land users wherever possible;
- Losses are compensated at replacement value;
• Affected people have access to a fair grievance mechanism, including a first tier of internal grievance review by the Project, with the opportunity for aggrieved individuals to resort to independent review of the grievance if a suitable resolution has not been agreed; and
• Vulnerable people, who may be more affected than others by the land acquisition process, will be identified and specifically assisted if and as needed.

Accordingly, it is considered that, as land will be acquired from the two land owners by way of negotiated settlement, within the context of a legal system that does not sanction expropriation or other compulsory procedures, any economic displacement impacts on the respective land owners will be identified and compensated accordingly as part of the negotiated settlement.

**Economic Displacement as a result of change in Land Use – Forest Land**

Approximately 3.7 ha of forested land will need to be cleared to allow for construction. While the original land use will be restored after construction where possible, approximately 2.1 ha of this cleared area will no longer be forested as trees and other deep-rooting vegetation will not be permitted to grow about the buried pipelines. The remainder of the land, required only during the Construction Phase, will be able to be replanted with trees.

The affected forested land is owned by the Russian Federal State Forestry Fund. Based on information at the time of writing, there is no indication that this land is commercially managed or used (either by the owner or by any third party) for economic or commercial purposes.

As per the Project Land Acquisition Policy, a negotiated settlement with the land owner will be reached, in accordance with Russian Federal law. Any impacts on the landowner identified as part of the land acquisition process will be taken into account as part of the negotiated settlement undertaken according to the Project Land Acquisition Plan.

Accordingly, it is not considered that there would be any economic impacts associated with either the permanent or temporary change of use of the land needing to be acquired.

### 14.6.2.1 Assessment of Potential Impacts (Pre-mitigation)

The following potential socio-economic impacts are assessed below:

- **Economic impacts:**
  - Employment generation;
  - Increased demand for goods and services;
  - Potential for Reduced business revenues:
    - Commercial fishing;
    - Shingari and Don holiday complexes;
    - Anapa Resort Town municipal district tourism industry; and
    - Varvarovka horse riding business.
  - Economic displacement of agricultural workers.

- **Community impacts:**
  - Reduced recreational amenity of Sukko and Shingari beaches;
- Reduced amenity for visitors to the Varvarovka village cemetery;
- Reduced cultural and aesthetic value of landscape; and
- Reduced residential amenity for residents of Varvarovka.

**Employment Generation**

At the peak of construction, the Project will employ approximately 2,000 people on the construction of all three sections (landfall, nearshore and offshore). The estimated peak labour numbers during the Construction and Pre-Commissioning Phase for each Project section are presented in Table 14.14, although each Project section peak will not occur simultaneously.

**Table 14.14 Estimated Labour Levels during the Construction Phase**

<table>
<thead>
<tr>
<th>Project Section</th>
<th>Peak Labour Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Landfall</td>
<td>330</td>
</tr>
<tr>
<td>Nearshore</td>
<td>544</td>
</tr>
<tr>
<td>Offshore</td>
<td>1,211</td>
</tr>
</tbody>
</table>

Most jobs on the Project will be relatively short or medium-term, lasting between several months and up to approximately two years, although a portion of the jobs may last throughout the Construction and Pre-Commissioning Phase. Figure 14.19 shows the anticipated profile of direct employment for the Project during construction. The figure demonstrates how employment will vary as construction progresses.

The construction of the landfall section will generate an estimated 330 temporary jobs during the peak of construction over a two quarter period (i.e. around the fourth and fifth quarter of landfall section construction activity). This estimate includes approximately 115 unskilled jobs (i.e. approximately 35% of jobs). Managerial and skilled jobs associated with the landfall section construction activity are likely to be filled by non-local workers brought on by the Contractor (i.e. approximately 215 jobs). However, it is possible that local workers will be hired to fulfil the unskilled and semi-skilled jobs; however, hiring will be at the discretion of the construction Contractor.

The construction of the nearshore and offshore sections will generate an estimated maximum of approximately 1,750 temporary jobs during the peak of construction approximately half way through the total construction programme. Given the specialised and technical nature of the offshore construction, it is expected that the Contractor will entirely provide the workforce for all nearshore and offshore construction and that few, if any, local people will be employed for this work.
Figure 14.19 Anticipated Profile of Direct Employment for the Project during the Construction and Pre-Commissioning Phase

Source: URS Analysis
Notes: The number of jobs shown per quarter and per section is an estimate; and does not indicate that employment will last for the entirety of the quarter concerned (i.e. the full three month duration).

In addition to any potential direct construction employment generated by the Project itself, through the construction Contractor, there will be an increase in local employment arising from indirect and induced effects of the construction activity. Indirect employment includes the procurement of goods and services from local companies which could generate jobs with these companies. Employment growth may therefore arise locally by way of indirect or supply linkage employment multiplier effects. The beneficial impacts of an increase in demand for goods and services are covered in the assessment of Increased Demand for Goods and Services below, including the use of the port at Novorossiysk. Additionally, part of the income of the construction workers and suppliers will be spent within the Local Communities and throughout the municipal district, generating further employment by way of induced employment multiplier effects.\(^{30}\)

\(^{30}\) The scale of the multiplier effects will depends on the size of the strength of internal local (both Local Community and ART municipal district) supply linkages and also the degree of income leakage that occurs from the area beyond its boundaries. It is considered that the ART municipal district is likely to have medium supply linkages based on the size and nature (i.e. sectoral composition) of its economy. However, it has not been possible to identify a quantitative multiplier by which to estimate the scale of indirect and induced employment that would be generated locally.
In summary, it is estimated that up to approximately 30% of the landfall section employment, or approximately 115 jobs, could be available to local workers, including workers from the Local Communities. However, local hiring will be at the discretion of the construction Contractor (as employment will not be directly with South Stream Transport). Although the number of local hires is likely to be limited (up to approximately 115 jobs), the Construction Phase will be likely to result in a short term and temporary, **Beneficial** economic impact for Local Communities as a result of the increase in available job opportunities.

An increase in job opportunities, albeit limited, in the Local Communities is a potential benefit of the Project. However, there is also the potential for negative sentiment to be generated within the community in relation to the employment of non-local labour. Specifically, this may arise in relation to:

- Unfulfilled local employment expectations and resentment between local people who are employed by the Project and those whose applications were unsuccessful, and between local and non-local workers if local people perceive that foreign workers are receiving better pay or conditions for the same job;
- Unfulfilled skill development and training expectations as the positions to be filled by workers local to the area are likely to be unskilled (or potentially semi-skilled) and short-term, and training of local workers associated with the Project – if it occurs – will be limited to the training required for these unskilled (or potentially semi-skilled) positions; and
- Increased tensions within the local communities over access to jobs and due to the presence of non-local workers in the area.

Enhancement and mitigation measures related to the benefit of local employment, potential expectations related to this and the potential for negative sentiment, are described in Section 14.5.2.2.

**Increased Demand for Goods and Services**

The Project will require the procurement of materials and equipment from locations in Krasnodar Krai, Russia and outside of Russia, resulting in a direct increase in the demand for goods and services. Therefore, the Project may result in opportunities for local suppliers and contractors to seek sub-contractor roles and/or supply materials and equipment to the Project and in Russian suppliers winning contracts to supply equipment (such as plant and construction vehicles) and materials, assuming they can meet the required Project specifications. At the time of writing, decisions regarding the supply of steel pipe are still under discussion. It is anticipated that the pipe to be used for the installation may come from pipe mills in Europe, Russia, Japan, and/or India. Accordingly, there is a good probability that pipe mills in Russia will supply at least some of the pipe required for the Project.

Based on the availability of existing suppliers, it is anticipated that contracts for construction activities, materials and shipping services that are fulfilled within Krasnodar Krai and Russia are likely to be from national businesses, with the possibility of some concentration within Krasnodar Krai.

Accordingly, the types of businesses that are likely to see an increase in demand for goods and services as a result of the project are:
• Construction material and equipment suppliers;
• Accommodation suppliers in the town of Anapa;
• Support services suppliers such as transport, catering and cafés / restaurants, cleaning and security; and
• Port-related businesses that serve the port of Novorossiysk, including shipping businesses, associated with the use of the port for the transport of materials, supplies and workers.

Additionally, there will be a requirement to accommodate the non-local Project workforce. Chapter 5 Project Description states that such workers will be lodged in nearby communities (i.e. not in a workers camp setting). This assessment assumes that they will lodge in the town of Anapa, given the broader and larger availability of accommodation options there compared to the much smaller Local Communities. It is estimated that, at the peak of construction activity in the landfall section up to 115 jobs will be unskilled / semi-skilled and potentially hired locally; this means that a peak of approximately 215 jobs would be filled by non-local workers needing accommodation in the area.

Local accommodation suppliers are likely to benefit from the demand for accommodation of the incoming workforce. This increased demand is expected to persist, at varying levels, for approximately two years. It is not expected that the number of non-local workers likely to lodge within Local Communities will be high enough to have any significant adverse impact on accommodation, food or other markets given the relative size of the municipal and regional markets, and the prominence of tourism in the area. Several million tourists visit the area annually, and no adverse impacts on housing, tourism, and leisure infrastructure or other markets are anticipated.

Demand for shipping services is likely to be limited, as many of the vessels required for the Project will be specialised and sourced internationally. However, there is likely to be demand for vessels to supply food, waste disposal and crew change services which could be sourced from the region’s ports. Additionally, the use of the ports will provide an economic stimulus for any port that is used and port-related services and supply chain businesses that will benefit in turn.

Considering all of the above, the increased demand for goods and services amongst national, regional and municipal district / local businesses will be a temporary but limited and beneficial contribution to the economy.

Potential for Reduced Business Revenues

Commercial Fishing Businesses

The Fisheries Study (see Appendix 14.1) examined the three potential risks to fisheries industry target species, as well as the potential for impacts on fisheries, that could arise as a result of construction of the nearshore and offshore sections of the Project. This study concluded that it is unlikely that there will be any distinguishable impact on the resource (i.e. fish stocks) or on the commercial fishing industry in general (individual employment or local business impacts) due to construction of the Project in the nearshore and offshore sections. A discussion of the key findings of the study follows below.
Potential impacts on fish and fishing could arise from construction activities through increased sedimentation, potential disturbance to fish due to noise and light, and the temporary establishment of a marine safety exclusion zone wherein access for vessels and activities unrelated to the Project will be restricted. The Fisheries Study has considered these potential impacts and concluded that there is unlikely to be any distinguishable impact on the resource (i.e. fish stocks) or on catch levels.

Sediment modelling (Appendix 12.2) was undertaken for all seabed intervention activities, such as dredging. The modelling showed that there will be some disturbance of sediment from dredging activities however the plume generated during dredging activities, disperses rapidly over 4 to 5 days from the activity ceasing and concluded that it will not be at an intensity or duration that would influence either the fish or the fishing. Underwater noise modelling (Appendix 12.3 UW Noise) was undertaken specifically for the Project which showed that sound levels generated by Project activities in Russia are insufficient to cause mortality or injury to fish. In addition, noise will only affect a localised group of individual fish over a short time period. Light from night-time works may affect fish, either by direct attraction or through alterations in the distribution of planktonic prey. However, the extent of the impact is limited to the immediate vicinity of the Project vessels. As such, the magnitude of impact on commercial fisheries is considered to be negligible (consistent with the conclusions reached in Appendix 14.1).

The 3 km-radius safety exclusion zone that will be in place around the pipe-lay vessel spread during construction of the nearshore and offshore sections will overlap with an area of fishing grounds. The safety exclusion zone will restrict navigation and fishing within the zone. However, the safety exclusion zone will only take up a small part of the existing fishing grounds at any one time, and will move with the progress of the pipe-lay vessel. In any given area, the safety exclusion zone will only be present for a short period (i.e. a few days during construction of the exit pits, and approximately 9 to 10 days per pipe-lay process from the exit pit to the edge of the fishing grounds at ca. 100 m water depth). Therefore, any fluctuations in effort and catch should be within, and indistinguishable from, normal annual variations.

Small scale commercial fishing companies are known to operate in the vicinity of the Project Area, in the Anapa district and could potentially fish within the Project Area (see Section 14.4.11). These fisheries companies include RPK Briz and OOO Ram which operate between one to three vessels and employ 15 to 30 people.

Given the information provided in Appendix 14.1 regarding the limited extent and duration of potential impacts, it is very unlikely that there would be a distinguishable impact, significant or otherwise, on any Russian fisheries, including the small scale commercial fishing companies operating in the ART area. Accordingly, the magnitude of impact on commercial fisheries is considered to be negligible.

Given the reliance of the fishing industry on the availability of fish stocks to support industry revenues and the livelihoods of workers in the fishing industry, the sensitivity of the commercial fishing industry is assessed as moderate.

Given the negligible magnitude of impact and the moderate receptor sensitivity, the impact on commercial fishing businesses in the Local Communities and those from the wider Krasnodar
Krai region will be **Not Significant**. This is consistent with the definition of a Not Significant adverse impact in Table 3.4 in Chapter 3 Impact Assessment Methodology, which states that “any impacts are expected to be indistinguishable from the baseline or within the natural level of variation”. Accordingly, no impacts on livelihoods of those working for commercial fishing businesses are expected.

**Shingari and Don Holiday Complexes**

If customers of the Shingari and Don holiday complexes are deterred from staying at the two complexes by impacts such as noise, dust or impacts on the seascape, then the businesses could in turn suffer deterioration in trade. For this reason the overall effect on amenity, as it would be experienced by guests at the complexes is relevant and is considered below.

Assessments have been undertaken to assess potential impacts related to air quality, dust, noise, vibration, changes to views and changes in water quality. For further information, refer to the respective Construction and Pre-Commissioning Phase impact assessments within Appendix 12.2, Chapter 9 Air Quality, Chapter 10 Noise and Vibration, and Chapter 13 Landscape and Visual. The following points summarise the residual impact findings of those assessments (based on the residual impact conclusions of the assessments, unless otherwise stated).

The air quality and noise and vibration assessments have not identified significant adverse residual impacts specifically in relation to Shingari and Don holiday complexes during the Construction Phase. However, the noise impact assessment has identified the potential for residual Low significance impacts during the Pre-Commissioning Phase on several receptors, including Shingari and Don holiday complexes. This impact is associated with the cleaning, drying and gauging of the Pipeline, and will last for 20 days and nights. The assessment is arrived at on the basis of impacts that will be experienced by residents during the night time.

The visual impact assessment (Chapter 13 Landscape and Visual) identified a potential adverse impact of moderate significance on the visual amenity for recreational visitors to the seashore, including the private beach in front of the Shingari and Don holiday complexes. Shingari and Don holiday complexes are the only tourism accommodation businesses specifically identified in the visual assessment with the potential to be directly affected due to their proximity to the nearshore section of the Project during construction activities.

In this case, the impact is related to the temporary presence of non-recreational vessels (i.e. the nearshore and offshore construction vessels) in the waters off the coast; at their closest, during the construction of the microtunnel exit pits, these vessels will be over 1 km away. The impact will be temporary and short-term as the construction vessels, in particular the pipe laying barge, will only be visible to visitors at Shingari and Don holiday complexes for a few

---

31 These are the only two businesses identified in the visual impact assessment; the customers of which would be directly impacted by the Project. Therefore, it is not considered that there would be significant impacts on any other tourism related businesses.

32 The landscape assessment takes account of two activities that will lead to this impact: firstly, the transfer of materials and equipment by vessel to the pipe-laying spread, and second, the operation of marine construction vessels.
days (or a week at most) during construction of each pipeline. With regard to the timing of the impact, it is potentially likely to occur on a single occasion during the main summer peak period, when occupancy of the holiday complexes would be at its highest.

Chapter 13 Landscape and Visual confirms that potential views inland towards the landfall section are prevented by the intervening coastal landform and woodland and so would not affect the visual amenity of visitors to the holiday complexes.

The Sediment Dispersion Study (Appendix 12.2) has modelled the dispersion of sediment plumes that could arise from construction in the nearshore section. This has shown that sediment is dispersed from each proposed dredging and disposal operation, a process that lasts 1.3 days per pipeline operation. Dredging activity could affect the quality of the water at the beach in front of the holiday complexes for short periods of time under certain conditions depending on the prevailing currents and the level of sediment suspension in the water. However, the modelling indicates that, even in a worst case scenario, any sediment plume impact on the beach would be minor and concentrated in any one area for less than 3 to 5 days per pipeline dredging activity. Accordingly, the potential that increased sediment in seawater would detrimentally affect guests at the holiday complexes is limited as the occurrence of any sediment plume will be limited in extent, dependent on tides, highly localised and occur over a very short term, with any impacts (if occurring) only lasting several hours or a few days at most.

The Shingari and Don holiday complexes are relatively small resorts that provide guests with use of a relatively private beach. The potential for adverse visual or water quality impacts on beach users could conceivably reduce the amenity experience of guests staying at the holiday complexes. This could in turn lead to reduced business revenues (e.g. if the company faces reduced bookings or needs to offer rate reductions as compensation). It is considered that this is unlikely given that both resorts mostly provide services for corporate groups and that individuals and families staying at the resort are less likely to have paid personally for their stay as many are organised under the corporate booking arrangement (see Section 14.4.3.3).

Impacts could potentially extend beyond the Construction and Pre-Commissioning Phase of the Project if guests are deterred and do not return for future trips. However, the limited duration of construction works in waters closest to the holiday complexes will in turn limit the duration of any impacts; as noted above, impacts on both views and the turbidity of the water are not expected to last more than a few days. As such, it is considered that the magnitude of impact on the Shingari and Don holiday complexes from a potential downturn in trade, due to visual and water quality effects on guests would be short term and of low magnitude.

Any construction vessels viewed from the beach would be seen in the context of commercial vessels on the existing shipping lanes and the impact of construction activity is unlikely to be of an extent which could prevent the holiday resorts from attracting and retaining guests. These changes are very short term (no more than a few days duration) and are not expected to cause hardship, degradation, or impair the function and value of the resource / receptor. However, given the importance of the holiday complexes’ setting and the private beach to the holiday complexes’ appeal to prospective guests, the sensitivity of the holiday complex to any adverse effects which might deter holiday makers from staying at Shingari and Don holiday complexes is considered to be moderate.
Given the low magnitude of impact and the moderate sensitivity, the overall impact significance will be **Low**.

**Anapa Resort Town Tourism Sector**

If tourists were deterred from visiting or staying in the Anapa Resort Town municipal district (and the tourist facilities of the town of Anapa and Sukko) by noise, dust or impacts on views, then the local tourism sector could in turn suffer deterioration in trade. For this reason the overall effect on the area’s amenity, as it would be experienced by tourists, is relevant and is considered below.

Other chapters have assessed the potential impacts of:

- Sedimentation affecting water quality along the coast (i.e. increasing the turbidity of coastal waters) as a result of construction in the nearshore section;
- Decreased air quality, including increased dust levels as a result of construction activity in the landfall section;
- Increased noise and vibration; and
- Changes to views

For further information refer to the respective construction impact sections within Appendix 12.2, **Chapter 9 Air Quality**, **Chapter 10 Noise and Vibration**, and **Chapter 13 Landscape and Visual**. Following is a summary of the residual impacts and conclusions of these assessments.

The Sediment Dispersion Study (Appendix 12.2) has modelled the dispersion of sediment plumes that could arise from construction in the nearshore section. This has shown that sediment will be dispersed from each proposed dredging and disposal operation, a process that lasts 1.3 days per pipeline operation. Dredging activity could affect the quality of the water at the nearby beaches for short periods of time under certain conditions depending on the prevailing currents and the level of sediment suspension in the water. However, the modelling indicates that even in a worst case scenario, any sediment plume impact along nearby beaches will be minor and concentrated in one area for less than 3 to 5 days per pipeline. Accordingly, it is considered that the risk of increased sediment in seawater detrimentally affecting the enjoyment of the beach for recreation will be limited; the occurrence of any sediment plume at the beach will be dependent on tides, highly localised and occur over a very short term, with any impacts (if occurring) only lasting several hours or a few days at most. **Chapter 9 Air Quality** and **Chapter 10 Noise and Vibration** do not identify any significant residual impacts on tourism areas or activities in the vicinity of the landfall or nearshore sections.

**Chapter 13 Landscape and Visual** identifies impacts of a moderate residual significance on a number of receptors. In each case, the visual impact assessment states the impacts will be temporary and short term. While these impacts may temporarily reduce the aesthetic value of the area, which could affect the enjoyment of some recreational activities for some people, they are unlikely to be of an extent which alter visitors’ use of any recreational or tourism resources in the area.
In regard to scuba diving, Chapter 17 Ecosystem Services identifies that there is a potential risk to scuba dive operators if sediment dispersal reduces seawater quality and clarity at diving spots used by diving tour operator businesses off the coast from Sukko. However, the extent of sediment blooms are likely to be small and of short duration (a matter of days). Alternative dive sites are also available and, as such, the significance of any impacts on divers and dive operators are likely to be low and easily avoidable. Further, while there is one dive site (the Gordipiya barge) located close to the nearshore section of the Project although the site lies outside of the safety exclusion zone and access will not be restricted. Therefore, there are unlikely to be impacts on scuba diving (commercial or recreational).

The concentration of the tourism sector in the town of Anapa and Sukko, with further attractions in the Bolshoi Utrish Nature Reserve, all places that are at some distance from the Project Area, means that visitors to the area are unlikely to experience any significant adverse impacts on their use or enjoyment of the area due to the Project’s construction. Accordingly, it is unlikely that the construction activity associated with the Project could restrict the ability of any individuals or businesses to derive a livelihood from tourism. As such, it is considered that the magnitude of the potential impact on the tourism sector due to construction of the Project will be low.

Given the importance of the tourism sector to the local economy and the value placed on the quality of the local environment by local tourism operators, the sensitivity of the tourism sector to any adverse effects which might deter tourists from visiting the area is considered to be moderate.

According to the matrix, given the low magnitude of impact and the moderate sensitivity, the overall pre-mitigation impact significance of the Project on the tourism sector will be Low.

Potential for Reduced Business Revenues (Varvarovka Horse Riding Business)

The operator of a horse riding business in Varvarovka has indicated that a novice trail riding route runs through the lands owned by Agrifirm Kavkaz. However, the operator was unable to indicate the precise route, and it has not yet been confirmed if this route overlaps with the Project Area. If the route crosses the construction corridor or any of the construction areas, access will be restricted during the period of construction, and the business will need to find a suitable alternative (beginning in Varvarovka and following a route that stays off the roads and stays in quiet, open country).

As it has not been possible to confirm the exact alignment of the novice route used by the horse riding business, the remainder of this assessment is based on a worst-case scenario, whereby it is assumed that the novice horse riding route will be severed during the Construction and Pre-Commissioning Phase. If this happened, the horse riding business would be directly impacted for the duration of this Phase, a period of approximately 15 months. The impact would most likely be temporary and reversible; although depending on the exact route used by the horse riding business and its intersection with the RoW and associated maintenance access roads; some minor adjustments to the route in the Operational Phase may be required. Overall, the magnitude of impact would be moderate.
Given that the novice route is only one route used by the horse business, and that there are other routes that the business may be able to utilise; the sensitivity of the receptor is considered to be moderate.

Taking this potential worst-case scenario into account, and given the moderate magnitude of impact and moderate sensitivity of the receptor; the potential impact significance is assessed as Moderate.

Economic Displacement of Agricultural Workers

Approximately 71 ha of land will be taken up (including temporary land use agreements) at the commencement of construction of the Project, including approximately 4 ha of forested land, 8 ha of meadows or shiblyak\textsuperscript{33}, and 54 ha of agricultural land. The remainder of land is used for existing roadways. This impact assessment considers the potential that land take associated with the Project could result in a loss of productive agricultural areas (i.e. productive vineyards), which could in turn trigger a loss of employment for the people who work these lands. As noted in Section 14.4.7, the vineyards in the Project Area belong to one owner, Agrifirm Kavkaz, owned in turn by a commercial residential development company, Fond Yug. Any potentially affected workers are employed by these owners.

Of the agricultural land that will be affected by the Project land take:

- In total approximately 11.8 ha of confirmed productive vineyards will be removed from productive use due to the Project, including 4.6 ha of vineyard within the potential transfer site\textsuperscript{34}, and 7.2 ha within the temporary construction area for the Varvarovka Bypass Road:
  - The majority (10.1 ha) of this removal will be temporary and limited to the duration of the construction works in the landfall section of the Project: a period likely to be for up to two years. Once construction is completed, it will be several years until mature, productive vineyards can be re-established on the land; however, during this time the replanting of vineyards will also require labour; and
  - The remaining 1.7 ha of currently productive land will be permanently lost due to road widening for the Varvarovka bypass road. However, these productive vineyards fall entirely within the proposed Chateau Club Village residential development; as such, without the influence of the Project, these vineyards would likely be sold to buyers within a number of individual plots after the completion of construction of the Project.

- The remainder of the agriculturally designated land is currently comprised of scrub, fallow fields and currently non-productive (apparently derelict) vineyards that have been abandoned for at least two to three years:
  - Of this land, approximately 7.0 ha will be permanently transferred to non-agricultural land uses in association with the landfall facilities; and

\textsuperscript{33} Evergreen and deciduous scrub and short trees.

\textsuperscript{34} The total area of the Potential Transfer Site is 5.38 ha. The difference between the total area and the figure cited for the area of confirmed productive vineyard that would be lost is due to the alignment of the Varvarovka Bypass Road through the Optional Transfer Site; accordingly that area is accounted for under the figure cited for the bypass road.
A further approximately 23.8 ha of land will fall within the permanent RoW, which will include provision for a small service track for the purposes of pipeline maintenance and inspection (accessible by 4x4 vehicles only). After construction, vegetation within the RoW will be reinstated, and access to the RoW will not be restricted by the Project. However, it is unlikely that vineyards will be replanted within the RoW, although seasonal crops may be established. As a result, the RoW land is likely to be removed permanently from productive use for a vineyard, but still available for other agricultural uses. The track could also be used by agricultural vehicles to facilitate access through and around the fields / vineyards.

Accordingly, although the majority of the affected 54 ha of designated agricultural land has been used for viticulture in the past, less than one quarter of this area is currently in productive use. It is further understood that there is sufficient land under production, with related tasks that can be undertaken, on the land cultivated by Agrifirm Kavkaz to ensure that the land take from the Project would not result in the displacement of workers, as activities and workers would be absorbed elsewhere in the vineyard. The total area of vineyard currently under cultivation by Agrifirm Kavkaz is 416 ha, whereas the area of productive land affected by Project land take amounts to only 11.8 ha, i.e. less than 3% of the area of vineyard currently under cultivation, not including other non-productive and fallow land nearby owed by Agrifirm Kavkaz. Other areas of vineyard owned by Agrifirm Kavkaz were abandoned (i.e. removed from active cultivation) two to three years ago; at this time workers moved to focus on other areas of the overall vineyard property and were not displaced as a result of the change.

Considering the total area of Project-related land take (temporary and permanent); the fact that affected productive land represents less than 3% of the landowner (Agrifirm Kavkaz) holdings; the past experience that has shown that vineyard activities and workers can be adjusted throughout the larger vineyard area; the duration of the impact and the fact that much affected land will be returned to its original use following construction; and the possible conversion of land within the RoW from vineyard to other agricultural purposes, it is not anticipated that there will be any economic displacement of agricultural workers (migrant or otherwise) as a result of the Project. As such, the magnitude of impact associated with the potential for the displacement of agricultural workers as a result of Project land take is assessed to be negligible.

In relation to potential economic displacement, the receptor is considered to be the workers who currently tend the productive vineyards. Although their employment is unlikely to be affected by the Project due to the capacity of their employer (Agrifirm Kavkaz) to utilise them on other areas of land, if an impact were to occur then these workers – particularly migrant

35 According to existing Russian regulations, it is unusual for anything except grass to be allowed to grow over a pipeline within a RoW of this kind. Although, it is understood that a potential precedent exists for replanting vines or other crops over the pipelines, it is considered unlikely that the land owner or manager would replant vines or other long term cultures over the pipelines because of the possibility that they may need to be dug up at any time in the Operational Phase to allow for maintenance of the pipelines, thereby causing substantial disruption. Therefore on balance, it is considered that the land that would remain within the permanent ROW would not be likely to be replanted with vines (even if the precedent can allow for it) but will be able to be planted with seasonal crops.

36 This was confirmed during the meeting with Fond Yug and Agrifirm Kavkaz (Ref. 14. 40) in which it was confirmed that the same workers come from Dagestan each year and that the number of workers had stayed reasonably constant over time.
workers from outside Russia – could face hardship in terms of lost income and livelihood. As such, the sensitivity of the workers employed by Agrifirm Kavkaz (including migrant workers) to a potential loss of employment is considered to be high.

Given the negligible magnitude of impact and the high sensitivity of the receptor, it is assessed that potential economic displacement, as a result of the Project land take and / or changes in land use, is an impact of **Low** significance.

**Potential for Reduced Recreational Amenity of Sukko and Shingari Beaches**

At its closest point, where it crosses under the shoreline within the microtunnels, the Pipeline alignment would be constructed approximately 3 km from Sukko beach; while the distance between the Pipeline alignment and Sukko beach, if measured looking perpendicular directly out to sea from the shoreline, is approximately 6 km (see Figure 14.18 which shows how the distance of the Pipeline alignment from Sukko beach varies along the Pipeline’s route).

From a socio-economic perspective, this assessment is concerned with whether impacts on amenity would materially compromise the ability of Sukko and Shingari beach users to use the beaches. Impacts on the amenity of the beaches may be associated with changes to the seawater at the beaches (e.g. increased turbidity, making it less appealing for swimming), as well as changes in the views seen from the beach. These issues have been investigated within other assessment chapters and are summarised below.

Appendix 12.2 has modelled the dispersion of sediment plumes that could arise from construction in the nearshore section. This has shown that dredging activity could affect the quality of the water at the nearby beaches for short periods of time under certain conditions depending on the prevailing currents and the level of sediment suspension in the water. However, the modelling indicates that even in a worst case scenario, any sediment plume impact along nearby beaches would be minor and concentrated in one area for less than 3 to 5 days per pipeline. Accordingly, it is considered that the risk of increased sediment in seawater detrimentally affecting recreational beach users will be limited as the occurrence of any sediment plume will be dependent on tides, highly localised and occur over a very short term, with any impacts (if they occur at all) only lasting several hours or a few days at the absolute most.

**Chapter 13 Landscape and Visual** has identified a potential moderate adverse residual impact in terms of the view from the seashore, including Sukko Beach and Shingari Beach, as a result of construction activities in the nearshore and offshore sections. This impact considers the fact that people on the beach will be able to see the construction vessels working in the sea, when these vessels are closer to shore. This impact will be temporary and short term, as the marine construction vessels, and in particular the pipe laying barge, will only be visible to beach users for a few days (or a week at most) during the construction of each pipeline; following construction, the impact will cease and beach users will not experience any impacts in relation to the operation of the Pipeline. Furthermore, commercial shipping vessels can often be seen in the shipping lanes off the coast; therefore, the presence of the Project’s construction vessels (anticipated to be an average of three vessels at any one time) is not expected to be unique or particularly intrusive.
Chapter 14 Socio-Economics

Considering the inputs from the sediment dispersion and visual impact studies, the potential impact on the recreational amenity of the Sukko and Shingari beaches is expected to be of low magnitude.

The receptor for this impact would be recreational beach users. The nature of the coast in this area means that users of Sukko and Shingari beach have little alternative to those beaches unless they travel over 10 km to the town of Anapa to use the beaches there. However, it is considered that amenity-related visual impacts do not materially compromise beach users’ ability to enjoy recreational activities such as swimming, playing, sunbathing, etc. As such, the sensitivity of Sukko and Shingari beach users to amenity-related impacts is moderate. It is noted that recreational beach users are likely to include children staying at the Smena Children’s camp. However, it is not considered that they are disproportionately vulnerable given the nature of the impact, compared with other beach users.

Given the low impact magnitude and the moderate sensitivity of the recreational beach users, the overall impact significance is assessed as Low.

Reduced Amenity for Visitors to the Varvarovka Village Cemetery

The landfall section of the Project will be constructed approximately 400 m southeast of the Varvarovka village cemetery (a Russian Orthodox and Armenian cemetery). Additionally, the cemetery will be located approximately 10 m south of Gazprom Invest Road and approximately 100 m west of South Stream Transport temporary microtunnel access road. The alignment of the South Stream Transport temporary access road has been designed to avoid running close to the cemetery.

This assessment is linked to the assessment in Chapter 16 Cultural Heritage on the Varvarovka village cemetery. However, from a socio-economic perspective, this assessment is concerned with whether impacts on amenity features (including noise and visual quality) would materially compromise the ability of visitors to the cemetery to use or enjoy the cemetery.

Chapter 10 Noise and Vibration has confirmed, in relation to Varvarovka village cemetery (identified as Receptor 13 in that assessment), that there would be no significant residual impact in relation to noise or vibration during the Construction Phase. However, the noise impact assessment has identified the potential for Low residual significance impacts during the Pre-Commissioning Phase.

Chapter 13 Landscape and Visual has identified a short-term Moderate residual visual impact on visitors to the cemetery, as visitors may be able to see construction activities on land and in the sea, including the construction and use of the access road along the northern and eastern boundaries of the cemetery.

Chapter 16 Cultural Heritage, taking account of the results of Chapter 10 and Chapter 13, has assessed that there could be a Low adverse residual impact on the tranquillity of the Varvarovka cemetery.

Given the potential for the Project to give rise to noise, vibration, visual and cultural heritage impacts on Varvarovka village cemetery users, as well as the extent, duration and reversibility of these impacts, the magnitude of impact is considered to be low.
The receptor for this impact would be visitors to the cemetery. Given that users of the cemetery are likely to value and also place significant importance on the existing quality of amenity provided for by the surrounding environment, it is considered that the sensitivity of visitors to the cemetery to amenity-related impacts would be high.

Given the low impact magnitude and the high sensitivity of visitors to the cemetery users, the overall impact significance is assessed as **Moderate**.

**Reduced Residential Amenity for Residents in Local Communities**

**Introduction**

The construction of the Project has the potential to affect the amenity of (i.e. the overall quality of the surrounding environment as experienced and enjoyed by) residential receptors in Local Communities. Amenity-related features include issues such as air, quality, dust, noise, vibration, and visual impacts. Accordingly, these impacts have been assessed in other chapters of this Report including Chapter 9 Air Quality, Chapter 10 Noise and Vibration, and Chapter 13 Landscape and Visual.

The potential for amenity impacts has been considered for all the Local Communities by having regard to these other chapters. However, a socio-economic residential amenity impact assessment is only considered warranted where there is more than one contributing amenity-related impact (i.e. air quality, dust, noise, vibration and/or visual impact) occurring simultaneously or continuously. Where this is not the case, there is no potential for such impacts to act in combination with one another to impact on residential amenity; the standalone impacts are assessed in their respective chapters.

The air quality, noise and vibration, and visual impact assessments have identified some Low residual adverse impacts and some Moderate residual adverse impacts on residential receptors within the Local Communities (for details, please see Chapter 9 Air Quality, Chapter 10 Noise and Vibration, and Chapter 13 Landscape and Visual). However, there is only one circumstance where two or more amenity-related impacts would be experienced by the same receptor and where that impact would also occur simultaneously or continuously. This is related to the construction and use of the Varvarovka Bypass Road and impacts on residents in North East Varvarovka. Accordingly, consideration of residential amenity impacts in this chapter is solely concerned with that circumstance and follows below.

**Reduced Residential Amenity for Residents in North East Varvarovka**

The Varvarovka Bypass Road will be constructed immediately to the southeast of residential dwellings in the north-eastern end of Varvarovka. Assessments have been undertaken to examine the likelihood of significant air quality, dust, noise, vibration, and visual impacts of the Project. For further information refer to the respective construction and pre-commissioning effects sections within Chapter 9 Air Quality, Chapter 10 Noise and Vibration, and Chapter 13 Landscape and Visual. Following is a summary of the residual effect findings of those assessments.

**Chapter 9 Air Quality** does not identify any Moderate or High significance residual air quality impacts on residential receptors at the north east of Varvarovka. With regard to dust from the
Varvarovka Bypass Road, this finding is based on the consideration that the implementation of good site practice and the stringent use of dust mitigation measures throughout all elements of the construction activities would be capable of controlling emissions, to the extent that the effect of any impact will not be significant.

**Chapter 10 Noise and Vibration** has assessed that there will be a Low adverse residual impact on residential dwellings (at Receptor 4, as identified in that assessment) due to traffic on the Varvarovka Bypass Road during the Construction Phase under Scenario 3 when the greatest road traffic flows will be experienced on the Varvarovka Bypass Road. The assessment has also assessed a Low adverse residual significance impact on the same receptors, together with receptors 1 and 3 at the southern tip and eastern edge (mid-way between the north and south of the community) of Varvarovka respectively, during the Pre-Commissioning Phase. This impact is associated with the pre-commissioning activities required for the Pipeline, and will last for 20 days and nights per pipeline. The assessment is arrived at on the basis of impacts that will be experienced by residents during the night time. It is important to note that this impact will not occur at the same time as the impacts from road traffic flows.

**Chapter 13 Landscape and Visual** has assessed Moderate significance residual impacts on residents due to disruptive views of the proposed acoustic barrier along the access road and limited views of construction work on the landfall section. In each case, the visual impact assessment states the impacts will be temporary and short term.

Taking account of the potential for the Project to give rise to noise, vibration, and visual impacts on residents in northeast Varvarovka, as well as the extent, duration and reversibility of these impacts, the magnitude of impact is considered to be low.

The receptor for this impact is the residents of Varvarovka. The degree to which amenity impacts will affect the quality of life of residents may vary depending on the nature of the impact. For example, noise impacts (particularly if occurring at night) and air quality impacts, may detract more from the quality of life for residents than noise impacts during the day or visual impacts. Therefore, the overall sensitivity of residents to amenity impacts is considered to be high; particularly in respect to the potential for night time effects. At other times, the sensitivity of residents to amenity-related impacts may be moderate.

Given the low impact magnitude and the high sensitivity of residential receptors, the overall impact on the amenity of residential receptors, based on the potential for significant night time noise impacts, is of Moderate significance.

**14.6.2.2 Mitigation and Enhancement**

Mitigation measures to address adverse impacts and enhancement measures which have the potential to enhance beneficial outcomes of the Project are set out below.
General Measures

Grievance Procedure

South Stream Transport has developed a Grievance Procedure for the South Stream Offshore Pipeline, which will guide the management of grievances throughout the Project lifecycle. The Grievance Procedure is referred to in Chapter 6 Stakeholder Engagement and further described in the Project Stakeholder Engagement Plan.

The Grievance Procedure will be implemented for the community by South Stream Transport and will ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way, following a standard procedure of investigation, analysis, and resolution. It will also ensure that resolutions are documented and communicated to the appropriate stakeholders.

The Grievance Procedure will include recourse to a Compensation Management Framework, to ensure that cases requiring some form of compensation are evaluated consistently and equitably.

Compensation Management Framework

In certain circumstances, where it has not been possible to adequately mitigate for a significant adverse impact by avoiding or minimising the impact, it may be appropriate to provide compensation. In other cases, new or different impacts may arise as the Project progresses, as a result of changing baseline characteristics, third-party actions beyond the control of the Project, and/or changes to the assumptions contained within this assessment. While South Stream Transport will monitor environmental and socio-economic conditions (see “Monitoring” below) and adjust or implement mitigation measures as needed, there may be circumstances requiring compensation, or outright claims for compensation, as a result of impacts that have occurred.

South Stream Transport will develop a Compensation Management Framework to guide the evaluation and determination of compensation measures. The Compensation Management Framework will capture the process and requirements for assessing compensation claims and implementing compensation measures. Compensation measures may include financial compensation or in-kind contributions.

Compensation may also comprise livelihood restoration measures, which will be specifically defined under a separate but related Livelihoods Restoration Framework (below). The Compensation Management Framework will be closely tied to the Grievance Procedure (above). Additionally, a specific component of the Construction Management Plans will also address the issue of compensation, with reference to the Compensation Management Framework and other plans and frameworks as appropriate.

---

37 A grievance is a formal complaint by an individual (or group) who feel they are, or have been, adversely affected by Project-related activities.
Compensation for economic loss would include circumstances where compensation would be able to mitigate the financial impacts associated with reduced revenues or increased costs to a business or individual that can be reasonably attributed to the construction of the Project. The Compensation Management Framework will ensure that possibly affected people or businesses are appropriately compensated for lost assets or access to assets.

As part of the process of implementing the Compensation Management Framework, South Stream Transport will work with the affected stakeholders in order to identify appropriate compensation or restoration measures.

The framework will set out certain criteria to ensure that compensation is paid consistently and equitably.

*Livelihood Restoration Framework*

It is not anticipated that the Project will result in any livelihood impacts warranting livelihoods restoration measures. However, the Project will develop a Livelihood Restoration Framework to provide for the possibility that livelihood impacts do occur. This Framework will define the process that will be undertaken to identify the need for specific livelihood restoration measures, and the development of these measures in consultation with affected stakeholders and relevant local agencies. The overall goal will be to ensure that affected livelihoods are restored, at minimum, to pre-impact levels.

*Ongoing Stakeholder Consultation*

South Stream Transport will continue a programme of stakeholder engagement and consultation throughout the Construction and Pre-Commissioning Phase. These engagement activities will be designed to facilitate dialogue with relevant stakeholders, including those potentially affected by the Project, or who are concerned about or interested in the Project. These activities will allow potential impacts, issues and concerns to be identified early on and addressed in an expedient manner. These activities will also inform stakeholders of upcoming construction activities, as well as Project Activities that have been completed, and provide advance warning of any anticipated changes. Ongoing and future stakeholder engagement activities are described further in the Stakeholder Engagement Plan for Russia.

*Community Investment Plan*

South Stream Transport will develop a Community Investment Plan to guide community investment initiatives and opportunities for the Project. Although not intended to mitigate or compensate for impacts of the Project, community investment can offer additional value and benefit to both the Project and local communities and stakeholders, in the form of enhancing or creating socio-economic benefits.

---

38 The IFC’s Strategic Community Investment Quick Guide (2010) stipulates the following: “Community investment is added-value investment. It should not be confused with a company’s obligations to mitigate or compensate local communities for environmental and social impacts caused by the project. These issues are addressed separately under IFC’s Social and Environmental Performance Standards. Nevertheless, the two are interrelated components of a holistic approach for managing company-community relationships.”
As such, South Stream Transport views community investment as a key mechanism to support community development and to establish a mutually beneficial relationship with the Local Communities. Under the Community Investment Plan, South Stream Transport will work with local stakeholders to identify potential community investment opportunities and initiatives. Local stakeholders will also be integrally involved in the design and implementation of such programmes.

**Enhancement of Local Economic Benefits**

*Labour Procurement*

Where practicable, South Stream Transport will encourage the use of local labour for the Project including by requiring its contractors to advertise suitable available positions in local and regional media, use local recruitment agencies and engage in other similar activities, so as to provide the opportunity for local people to access employment opportunities created by the Project. Local employment will also be supported by local business contracts that may arise through goods and services procurement (below).

The intention of South Stream Transport to require its contractors, where practicable, to provide the opportunity for local people to seek employment opportunities on the Project, will also assist in addressing the potential for tensions related to unmet employment opportunities. To mitigate further these risks, South Stream Transport will keep communities informed about Project activities; in addition, the Grievance Procedure will provide a means by which the Company will receive and resolve any grievances arising from Project activities.

*Goods and Services Procurement*

Where practicable, South Stream Transport will encourage the procurement of local goods and services for the Project including by requiring its contractors to advertise suitable available contracts for the provision of goods and services in local and regional media, establish contacts with the local Chamber of Commerce and business associations and engage in other similar activities, so as to provide the opportunity for local suppliers and contractors to seek subcontractor roles and/or supply materials and equipment to the Project.

**Mitigation Specific to Potential Adverse Impacts on Businesses, Livelihoods and Local Communities**

*Mitigation for Potential for Reduced Businesses Revenues for Commercial Fishing Businesses*

The General Measures at the start of this section, Section 14.6.2.2, will apply as appropriate.

Potential impacts on fishing businesses will be mitigated through ongoing stakeholder engagement, the Grievance Procedure, and the Compensation Management Framework, as well as the following measures:

- The coordinates and timing of temporary marine exclusion zones will be communicated to vessel operators through the routine channels of the appropriate maritime authorities; and
- Additional meetings with marine area users (including fishers), as required, to further explain the temporary exclusion zones and address questions and concerns.
Mitigation for Potential Reduced Business Revenues for Shingari and Don Holiday Complexes and Anapa Resort Town Tourism Sector

The General Measures at the start of this section, Section 14.6.2.2, will apply as appropriate.

Plans indicating the Pipeline route and construction phase vessel spread along with timing of construction activities will be provided to the relevant authorities for distribution to local businesses as appropriate, including Shingari and Don holiday complexes.

For visual impacts that have not been avoided through design controls, Chapter 13 Landscape and Visual has set out mitigation measures to mitigate visual impacts. Specifically, to mitigate impacts on recreational visitors to the seashore, including the public beaches at Sukko and Anapa, and the private beach at the Shingari and Don holiday complexes, mitigation includes: Phasing construction; avoidance of night-time construction activities as far as practicable; and directional shielding for lighting on vessels, other than navigational lights on vessels.

Additionally, Chapter 12 Marine Ecology sets out measures to prevent sedimentation impacts on recreational water users along the coast line.

Mitigation for Potential Reduced Business Revenues for Varvarovka Horse Riding Business

The General Measures at the start of this section, Section 14.6.2.2, will apply as appropriate.

The assessment of the potential for reduced business revenues on the Varvarovka Horse Riding Business has been made on the basis of a worst-case scenario; given that the precise location of the novice route used by the business has not been able to be confirmed at the time of writing. The following mitigation is therefore premised on the basis of the assumption that the route used by the business will be severed for the duration of the Construction and Pre-Commissioning Phase.

The Project will work with the Varvarovka Horse Riding Business to undertake further investigation to check the horse riding route prior to construction to understand whether or not there may be an impact on the horse riding business if the route is not usable during the construction period and, if so, whether mitigation is required.

If access to all or part of the horse riding route is restricted or severed by the Project, South Stream Transport will work with the business owner to identify a suitable alternative. Whether or not an alternative can be found, the Compensation Management Framework and Livelihood Restoration Framework will also apply in the event that impacts on business revenues are evident. South Stream Transport will also engage with the stakeholder prior to and throughout the Construction and Pre-Commissioning Phase to ensure that the stakeholder is informed of Project activities and restrictions, and to understand any concerns the stakeholder may have. The Grievance Procedure will also apply to any complaints related to horse riding and related business impacts.

Mitigation for Potential Economic Displacement of Agricultural Workers

The General Measures at the start of this section, Section 14.6.2.2, will apply as appropriate.
After construction, all land that is not required for permanent aboveground infrastructure in the Operational Phase will be reinstated to a state as near to the original condition as possible or to a form in keeping with the surrounding topography where this is not precluded by risk to integrity of the Pipeline or erosion considerations. All necessary actions will be applied to ensure that reinstated land can function, at minimum, as productively as that prior to land acquisition.

**Mitigation for Potential Impacts on the Recreational Amenity of Sukko and Shingari Beaches**

The General Measures at the start of this section, Section 14.6.2.2, will apply as appropriate.

Specific to recreational beach users, the Project will provide regular updates to beach users regarding construction activities and schedule, both on land and at sea. Updates and information provided to beach users will also include information about how interested parties can contact South Stream Transport with questions, concerns or complaints.

As set out in respect to the potential for reduced business revenues on Shingari and Don holiday complexes and the Anapa Resort Town tourism sector, **Chapter 13 Landscape and Visual** has set out mitigation measures to mitigate visual impacts. Likewise, **Chapter 12 Marine Ecology** also sets out measures to prevent sedimentation impacts on recreational water users along the coast line.

**Mitigation for Potential Impacts on Visitors to the Varvarovka Village Cemetery**

**Chapter 16 Cultural Heritage** presents the mitigation measures to address the moderate adverse significance impact on the tranquillity of cemetery users, including the preparation of a Construction Traffic Management Plan. See Chapter 16 for more detail.

**Mitigation for Potential Impact on the Residential Amenity of Residents in Varvarovka**

**Chapter 10 Noise and Vibration** and **Chapter 13 Landscape and Visual** have proposed mitigation to address potential impacts related to noise and visual amenity, respectively, on residential receptors in the north-east of Varvarovka. For noise impacts, this includes the implementation of a three metre high acoustic screen along the boundary of the properties and Varvarovka bypass access road. The visual impact assessment has taken account of the presence of this screen in making an assessment, and has identified the following measures to address the visual impacts, including; the use of suitable vehicles and good vehicle maintenance on a regular basis to reduce visibility of exhaust emissions; removal of acoustic barriers as soon as possible; and the phasing of construction. See Chapter 10 and Chapter 13 for more detail on the mitigation that is proposed.

**Monitoring**

Monitoring of the socio-economic (and bio-physical) environment will be undertaken in order to ensure that impacts are appropriately managed. An outline of the monitoring that will be undertaken as part of the Project is contained within each of the assessment chapters, including, but not limited to, monitoring of:

- Air quality;
- Noise;
• Landscape and visual amenity; and
• Seabed sediment and marine water quality.

Chapter 22 Environmental and Social Management details the approach that will be taken to monitoring and includes an outline of key monitoring activities. Further information on monitoring including key receptors, monitoring locations and monitoring frequency will be contained within the monitoring program developed for the Project.

Ongoing stakeholder engagement will also serve as a means of monitoring impacts on potentially affected stakeholders, to ensure that the actual level of impact is not greater than predicted. If additional significant impacts are identified and verified, these will be a priority for resolution which will be agreed in consultation with affected stakeholders.

Shingari and Don Holiday Complexes

The results of the relevant monitoring programmes (as measured at relevant monitoring locations) will be communicated to Shingari and Don holiday complexes via the ongoing consultation that will be conducted with the two businesses regarding the Project constructions activities in the nearshore and offshore sections. This will assist with monitoring potential Project impacts and help to determine whether environmental and social changes are attributable to construction activity, and provide a basis for aiding resolution of any grievances.

Sukko and Shingari Beach Users

The users of the Sukko and Shingari beaches are likely to be a diverse, changing and temporary group of stakeholders (a mix of residents, local visitors, tourists from outside the region, etc.) and therefore cannot be specifically contacted. For this group, ongoing stakeholder engagement using communication channels that are likely to reach a diverse range of beach users will be utilised to communicate updates about the Project and activities, relevant monitoring results and ways in interested parties can access further monitoring details, as well as how to contact South Stream Transport with questions or concerns. This will assist with monitoring potential Project impacts and provide a basis for aiding resolution of any grievances.

Land Use and Ownership Monitoring

Monitoring will be undertaken via ongoing consultation with the two affected land owners to ensure that no unexpected land use issues arise during the Construction and Pre-Commissioning Phase. Monitoring will include discussions with Agrifirm Kavkaz to confirm that there is no decrease in demand for labour associated with the Project land take and that Project land take does not preclude use of fields not within the Project footprint.

Community and Local Economy Monitoring

In light of the nature of the Project and existing baseline conditions, the impact assessment has not identified any significant impacts on the Local Communities with the exception of the potential for short term, Moderate adverse residual impacts on residential amenity in North East Varvarovka. The impact assessment has also not identified any significant impacts on the
economy within the Local Communities that would require a targeted monitoring programme beyond those already discussed.

Nevertheless, regular social and economic monitoring will be undertaken during the Construction and Pre-Commissioning Phase. The key purpose of the monitoring will be to monitor social and economic conditions in case the Project gives rise to any unanticipated social or economic changes within the Local Communities, and if so, to allow for the early identification of these changes and for further mitigation measures to be implemented, as required.

Monitoring will consist of general socio-economic monitoring in tandem with ongoing stakeholder engagement and will cover the following matters:

- Hiring of workers from the Local Communities;
- Procurement of goods and services from local businesses;
- The number of non-local workers employed on the Project, their accommodation status (including type and location of accommodation) and any noticeable increase in demand for local services and facilities (e.g. health facilities) by non-local workers on the Project; and
- Any incidents of anti-social behaviour or crime, associated with the presence of non-local workers within the Local Communities.

In addition, fish catches are also monitored through the official statistics maintained by the relevant fishing authority, VNIRO; this data will be requested if needed to support discussions with stakeholders and/or the resolution of potential grievances. In addition, the Grievance Procedure and ongoing stakeholder engagement will also serve to monitor impacts and perceptions amongst the Project’s stakeholders.

### 14.6.2.3 Residual Impacts: Construction and Pre-Commissioning

Table 14.15 presents a summary of the potential residual socio-economic impacts arising from the Construction and Pre-Commissioning Phase of the Project. These residual impacts are assessed following the application of the mitigation measures identified above.

#### Beneficial impacts

The Project will result in a number of **Beneficial** but limited residual impacts, *inter alia*:

- Local and regional businesses will benefit from spending on goods and services (including accommodation and related services). Although limited due to the specialised nature of the Project construction, South Stream Transport will encourage the use of local services and contractors where practicable. The use of local businesses may also generate employment for local residents; and
- Local workers may gain employment with the Project. Although limited due to the specialised nature of Project construction, South Stream Transport will encourage local hiring when practicable, particularly in relation to unskilled / semi-skilled positions for the construction of the landfall section. Local hiring will have added benefits in terms of enhancing household incomes.
**High Adverse Impacts**

No residual **High** adverse impacts are anticipated.

**Moderate Adverse Impacts**

One residual **Moderate** adverse impact is anticipated:

- The potential impacts on the residential amenity for receptors in north-east Varvarovka arising as a result of noise and visual impacts acting together. The mitigation proposed to reduce noise impacts, specifically a three metre high acoustic screen, has also taken into account the landscape and visual assessment. Mitigation measures specific to these impacts have been identified has been taken account of in the amenity assessment, and therefore the residual impact assessment remains unchanged. It is important to note that the overlap of noise and visual impacts will be short-term and temporary.

**Low Adverse Impacts**

Three residual impacts of **Low adverse** significance are anticipated in relation to the following impacts:

- The potential for Economic Displacement of Agricultural Workers working on Agrifirm Kavkaz-managed land owing to the take up of approximately 12 ha of vineyard during construction. Although a Livelihood Restoration Framework will be part of the Project ESMS; it is considered that the residual impact would remain unchanged; owing to the nature of the process required to restore livelihoods to pre-impact levels, should that be necessary. It is important to note that, based on the assessment of impact magnitude, it is not anticipated that there will be any economic displacement of agricultural workers (migrant or otherwise) as a result of the Project. However, the significance of the impact has been arrived at based a cautious assessment that has taken account of the potential vulnerability of workers – particularly migrant workers from outside of Russia – and the hardship they could face in terms of lost income and livelihood, if economic displacement were to occur;

- The impact on the enjoyment by recreational users of Sukko and Shingari beaches due to visual disturbance as a result of the view of construction vessels working in the marine area, and also possibly as a result of suspended sediment in the sea water at the beaches over a short term period. However, it is important to note that this impact will be short-term, temporary, and not out of character as the beach has views of existing Black Sea shipping lanes; and

- The potential impact on the amenity experienced by visitors to Varvarovka village cemetery due to noise and visual disturbance associated with construction of the landfall section of the Project, including that arising from the presence of a temporary access road to be constructed by South Stream Transport near the cemetery. The design control of routing the temporary access road in order to leave a land and vegetation buffer between the road and the cemetery, along with the preparation of a Construction Traffic Management Plan, have contributed to a reduced residual impact on cemetery visitors.

Not Significant Impacts

The remaining residual impacts have all been assessed as being Not Significant and are not considered to be of concern to the Project in accordance with the proposed design controls, mitigation measures, management plans, and stakeholder engagement that will be carried out throughout the Construction and Pre-Commissioning Phase. This includes two Low adverse impacts on commercial tourism businesses which it is considered would be successfully mitigated for, if required, through the application of the Compensation Management Framework.

14.6.3 Impact Assessment: Operational Phase

14.6.3.1 Introduction

The following section identifies the potential impacts and risks to socio-economic receptors during the Operational Phase. For those effects where potentially significant pre-mitigation impacts are assessed (Section 14.5.3.2), potential mitigation measures have been identified (Section 14.5.3.3). This is followed by a residual impact assessment, the results of which are set out in (Section 14.5.3.4). There are some potential impacts that were not assessed for the Operational Phase and these are described below.

The Project will not create permanent employment opportunities during the Operational Phase. Therefore, any employment will be limited, occasional and temporary. Similarly, any goods and services required will be occasional and short-term. Therefore, these have not been included in the following assessment.

As demonstrated in the Appendix 14.1, the safety exclusion zones will not result in any adverse significant adverse impacts on fisheries during the Operational Phase. Furthermore, the following management measures have been committed to:

- In addition, as part of the Health and Safety Plan that will be prepared by South Stream, information on the position of the pipelines and the marine area exclusion zones / restricted areas will be provided to the relevant authorities to inform navigation charts for marine stakeholders identifying marine exclusion zones through the Operational Phase.

- The Health and Safety Plan will need to be communicated to fishing vessel operators, particularly any trawling companies, to minimise the risk of any accidents involving fishing boats and vessels.

All land that is required permanently by the Project for the establishment of landfall facilities and a permanent RoW along the Pipeline corridor will be acquired prior to the start of construction. Accordingly, the potential for impacts associated with land acquisition on land use have been considered within Section 14.5.2.
14.6.3.2 Assessment of Potential Impacts (Pre-mitigation)

Increased Demand for Russian Goods and Services (gas) and Increased Government Revenues, Taxes and Royalties

The total current gas pipeline capacity between Russia and Europe is approximately 200 bcm/year, which will increase to 318 bcm/year if South Stream and other new projects are completed. This could in turn lead to an increase in Russian gas production and sales. In this case, the Project would give rise to increased tax revenues for the Russian government of several billion euros annually.

As a result, the Project would, under this assumption, give rise to a Beneficial impact in terms of increased government revenues.

Fees are also payable for waste transportation and disposal, government approvals and permits. However, these fees are mainly levied to cover administrative costs and do not represent a net additional benefit to the tax base. Additionally, they are relatively modest in the context of overall government revenues so they will not yield a noticeable beneficial increase in national revenues.

Reduced Property Values

In addition to the permanent RoW (the impact of which has been assessed in Section 14.5.2.139), three Safety Exclusion Zones around the landfall section of the Project will be in place throughout the Operational Phase for the protection of public health and infrastructure. These zones will be measured from the centreline of the outermost pipelines for areas and encompassing land within three concentric rings surrounding the Pipeline and landfall facilities. These zones will place differing restrictions on land uses, according to distance from the Pipeline and landfall facilities, on the structures and activities that are prohibited within the zones, as follows:

- Exclusion Zone 1: Between 19 and 260 m from centreline of outermost pipeline: C and E-class: no isolated buildings (1-2 levels), dachas, agricultural farms\(^{40}\) (covering 166.4 ha);
- Exclusion Zone 2: Between 260 and 345 m from centreline of outermost pipeline: B-class: no cities, settlements, apartments of three levels or more, no developments / buildings with less than 100 people (covering 64.7 ha); and
- Exclusion Zone 3: Between 345 and 410 m from centreline of outermost pipeline: A-class: no airports, railways station, no developments / buildings with population of more than 100 persons (covering 50.1 ha).

\(^{39}\) All land that is required permanently by the Project for the establishment of landfall facilities and a permanent RoW along the pipeline corridor will be acquired during the Construction and Pre-Commissioning Phase.

\(^{40}\) It is understood that this relates to buildings but that farming activity, e.g. agriculture, growing vines, etc. will be allowed.
Most of the land that would be included within these zones is agricultural or forest land and accordingly, industrial, commercial or residential development is not permitted. As such, the proposed safety exclusion zones would not constrain the permitted use or development of that land, and there will be no impact associated with the establishment of the safety exclusion zones for the owners or users of that land.

However, the restrictions of the safety exclusion zones could have the potential to reduce land values for private owners of sites upon which existing, proposed or permitted land uses will be precluded by the Safety Exclusion Zones, should such a scenario arise.

A part of the Safety Exclusion Zone 3 to the south of the Pipeline alignment just east of the Anapa-Sukko road, overlaps with a small area of land that falls within the southern extension of Varvarovka allowed for by the Anapa GDP and which is identified as a housing development zone in the Anapa GDP (Ref. 14.14). This land is also within the Anapolis Resort residential project which is proposed for development by Fond Yug. However, the housing zone allowed for by the Anapa GDP allows for 'cottage development' and this type of development is permissible within the development restrictions applicable within the outermost Safety Exclusion Zone 3.

Further, it appears that a very small part of Safety Exclusion Zone 3 overlaps with part of the Chateau Club Village residential and vineyard development. However, it is understood that the development falls outside of the designated boundary (i.e. urban limits) of the Varvarovka community as set out in the Anapa GDP. An illustrative plan of the development available on the development website indicates that, at the most, only one dwelling would be located within the Safety Exclusion Zone 3. Therefore, as with the Anapolis development, it would appear that the proposed development is permissible within the development restrictions applicable within the outermost Safety Exclusion Zone.

Accordingly, the overlap between Safety Exclusion Zone 3 and the land in question that falls within the southeast and northwest extremities of the Project Area will not preclude development as allowed for within the Anapa GDP. Accordingly, there would not be any impact on the land.

On this basis, although the imposition of safety exclusion zones associated with the Operational Phase would be permanent in effect, they would not restrict the development potential of the site as allowed for by the Anapa GDP. Hence, there would not be any impact on land owners.

However, it is understood that the Anapa GDP was recently amended to accommodate the Project and it is possible that the amendments to the plan have reduced the value of the land in question. Additionally, the proximity of the developments to the scheme may reduce the final sale values that the developer is able to achieve. Therefore, the land value may be reduced.

Given the potential for reductions in land value, South Stream Transport will complete a negotiated settlement with the land owner, Fond Yug, in accordance with South Stream Transport’s Land Acquisition Plan. The Plan has been drafted in accordance with Russian legislation and the objectives of IFC PS5, applying the higher of the two standards wherever they are not consistent. The Plan provides for compensation, including for any reduction in land values as a result of the Project, based on a valuation mechanism conducted in accordance with the objectives of IFC PS5 or national legal requirements, whichever is the greater. The amount of compensation is being determined by an internationally recognised independent third party.
and the scope of work for the valuation has been agreed by both South Stream Transport and Fond Yug. Accordingly, any financial impacts on the landowner identified as a result of the establishment of the safety exclusion zones associated with the Operational Phase will be taken into account as part of the negotiated settlement undertaken according to the Land Acquisition Plan and national regulations. Further details on the approach to compensation for any reductions in property values as a result of the Project can be found in the South Stream Transport Land Acquisition Plan.

Taking account of all factors, it is considered that the magnitude of impact would be low. Given that the scale and geographical breadth of Fond Yug’s investments, it is considered that the organisation has low sensitivity. As such, it is assessed that any reduction in land value, if occurring, will have a Low adverse significance impact on the receptor.

### 14.6.3.3 Mitigation and Monitoring

The mitigation recommended in relation to each of the significant adverse impacts is set out below. Enhancement measures, which have the potential to enhance beneficial outcomes of the Project, are also addressed.

**General Mitigation and Enhancement Measures**

The general mitigation and enhancement measures presented in Section 14.5.2.2 in relation to the Construction and Pre-Commissioning Phase (i.e. the Grievance Procedure; the Project Compensation Management Plan; and ongoing Stakeholder Engagement) will all apply in the Operational Phase. Each measure will be tailored as appropriate to the Operational Phase. Further detail in relation to the Grievance Procedure and stakeholder engagement is provided below.

**Grievance Procedure**

South Stream Transport will continue to implement the Grievance Procedure throughout the Operational Phase with any necessary revisions to ensure it is appropriate to this phase of the Project. As during construction, the Grievance Procedure will ensure that complaints and grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way, following a standard procedure of investigation, analysis, and resolution. It will also ensure that resolutions are documented and communicated to the appropriate stakeholders. The Grievance Procedure is referred to in Chapter 6 Stakeholder Engagement and further described in the Stakeholder Engagement Plan.

**Ongoing Stakeholder Engagement**

Information on restricted areas under the onshore and marine safety exclusion zones will be provided to the relevant authorities to inform navigation charts for marine stakeholders identifying marine exclusion zones through the Operational Phase.

As for other groups (and the public), South Stream Transport will continue a programme of stakeholder engagement throughout the Operational Phase. These engagement activities will be commensurate with the level of Project activities and all stakeholders will be informed of any significant upcoming activities and changes, as appropriate. The stakeholder engagement
activities are described further in the Stakeholder Engagement Plan and in Chapter 6 Stakeholder Engagement.

Economic Impacts

Mitigation in case of Reduced Land Values

South Stream Transport will consult the Russian authorities and obtain the necessary permits and consents for all activities. As part of South Stream Transport’s Stakeholder Engagement Plan, consultation with affected landowners and implementation of the Grievance Procedure will help to ensure a timely and appropriate response to concerns by landowners and that any issues raised are addressed accordingly.

South Stream Transport will complete a negotiated settlement with the land owner, Fond Yug, in accordance with South Stream Transport’s Land Acquisition Plan. The Plan has been drafted in accordance with Russian legislation and the objectives of IFC PS5, applying the higher of the two standards wherever they are not consistent. Any financial impacts on the landowner identified as a result of the establishment of the safety exclusion zones associated with the Operational Phase will be included as part of the negotiated settlement. Further details on the approach to compensation for any reductions in property values as a result of the Project can be found in the South Stream Transport Land Acquisition Plan.

Monitoring As set out in Chapter 22 Environmental and Social Management, an overarching Operations Management Social Plan and an Employment Plan will be implemented in the Operational Phase. In light of the nature of the Project and existing baseline conditions, the Operational Phase socio-economic impact assessment has not identified any significant impacts and therefore assessment of those issues which would usually be monitored has been screened out. It is not foreseen that any issues would require a targeted monitoring programme beyond those already discussed.

Nevertheless, socio-economic issues and concerns will be monitored through the ongoing stakeholder engagement program and Grievance Procedure, and solutions to issues or grievances will be developed in consultation with affected stakeholders. If the Project does give rise to any unanticipated social or economic adverse changes within the Local Communities, it will allow for mitigation measures to be developed and implemented, if needed.

14.6.3.4 Residual Impacts: Operational Phase

Table 14.16 presents a summary of the potential Operational Phase residual socio-economic impacts arising from the Project following application of the identified mitigation measures.

Beneficial Impacts

The Project will result in the following Beneficial residual impacts, *inter alia*:

- Increased government revenues.

Table 14.16 Summary Table – Residual Socio-economic Impacts during Commissioning and Operational Phase
Adverse Impacts

There would be no residual adverse impacts on receptors as a result of the commissioning and operation of the Project.

Not Significant Impacts

The remaining impacts are all Not Significant and are not considered of concern to the Project.

14.6.4 Impact Assessment: Decommissioning Phase

The Project will be decommissioned many years into future and impacts during the Decommissioning Phase depend on the alternatives chosen at that time – preservation of the pipelines in place or complete or partial removal. If the latter option is chosen and construction activities (e.g. excavation, removal of pipeline, land rehabilitation) are carried out or construction equipment is used, then impacts are expected to be similar to those assessed in Section 14.5.2 in relation to the Construction Phase – i.e. generation of employment (beneficial impacts), increased demand for goods and services (beneficial impacts), and impacts on land users (potentially adverse, depending on whether or not productive land uses such as agriculture were disturbed). However, such impacts are likely to be at lower levels and short-term. Assuming that the restriction on areas governing the type and scale of development that can take place on land within certain circumference of the Pipeline are removed, there may be beneficial impacts for land owners associated with the liberalisation of development rights.

A careful record and archive of construction and operation activities will be maintained in a suitable format for future users of such information. It will include any special mitigation measures that were applied retrospectively, in addition to those identified prospectively in this impact assessment. It will also record all unexpected events that occurred during the Construction and Pre-Commissioning and Operational Phases of the Project.

14.7 Unplanned Events

The potential impacts associated with unplanned events are discussed in Chapter 19 Unplanned Events.

14.8 Cumulative Impact Assessment

The cumulative impacts associated with the Project relating to socio-economics are assessed in Chapter 20 Cumulative Impact Assessment.

---

41 The Project Life (i.e. the duration of the Operational Phase) is estimated to be approximately 50 years. As such, decommissioning would take place sometime in the mid to late 2060s.
14.9 Human Rights

Terms to Know – Human Rights

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Actual human rights impact</td>
<td>An &quot;actual human rights impact&quot; is an adverse impact that has already occurred or is occurring.</td>
</tr>
<tr>
<td>Potential human rights impact</td>
<td>A &quot;potential human rights impact&quot; is an adverse impact that may occur but has not yet done so. Potential impacts are analogous to human rights risks, i.e. the risks that an activity may lead to one or more adverse human rights impacts.</td>
</tr>
<tr>
<td>Adverse human rights impact</td>
<td>An &quot;adverse human rights impact&quot; occurs when an action removes or reduces the ability of an individual to enjoy his or her human rights.</td>
</tr>
</tbody>
</table>

According to UN Guiding Principles on Business and Human Rights (Ref 14.69), companies should respect Human Rights in projects and operations by seeking to prevent or mitigate potential Human Rights issues that may be caused directly by a Company’s projects or operations, or by project partners and suppliers. According to IFC Performance Standard 1, "each of the IFC Performance Standards has elements related to human rights dimensions that a project may face in the course of its operations. Due diligence against these Performance Standards enables companies to address many relevant human rights issues in its project.” The UN Guiding Principles, the IFC Performance Standards and other International Labour Organisation (ILO) standards are the benchmark for guiding companies in ensuring respect for Human Rights.

Russia is a signatory and party to many International Human Rights Conventions and Legislation which are detailed in Chapter 2 Policy, Regulatory and Administrative Framework.

Due to the fact that Human Rights factors are most usually linked with socio-economic factors, this section of the chapter discusses the findings of the Human Rights Due Diligence process.

14.9.1 Due Diligence Process

As previously discussed, the Project is not considered high risk from a socio-economic standpoint and there are no significant socio-economic triggers which would necessitate a Human Rights Impact Assessment separate from the ESIA. However, South Stream Transport undertook a voluntary Human Rights Due Diligence complementary to the environmental and social risks and impact identification process. The Due Diligence process also allows the Project to ensure there is a system in place to proactively monitor potential issues and concerns throughout the Project’s lifecycle.

The goals of the Project’s Due Diligence process were to:

- Identify, prevent, mitigate and account for actual or potential Human Rights impacts;
- Ensure policies and processes to manage Human Rights issues are in place;
• Express commitment to respect Human Rights through a policy endorsed by senior leadership;

• Ensure communication takes place with stakeholders about how issues will be addressed; and

• Ensure a Grievance Procedure is in place to enable Local Communities and other stakeholders to raise any human rights issues.

A Human Rights register was produced which identified the various elements of the Project and their interaction with actual or potential Human Rights impacts. Wherever possible, Human Rights mitigation and monitoring efforts to address these impacts tie into the Project’s existing corporate standards, policies, and procedures as outlined in the Environmental and Social Management Plan (ESMP) (see Chapter 22 Environmental and Social Management). A summary of the potential impacts and related Project responses are provided below.

The Due Diligence process recognises that the Human Rights risks may change over time as the Project evolves from the Construction and Pre-Commissioning Phase through the Operational Phase into the Decommissioning Phase. As such, the Project’s Human Rights Due Diligence is an iterative process whereby business operations and operating context will be examined on a regular basis.

14.9.2 General Policies and Procedures

During the Due Diligence process, all Corporate and Project policies, plans and procedures were reviewed to ensure a commitment from the senior level of management to protect and manage Human Rights. In addition, contractual language was reviewed to ensure that business relationships, including subcontractors and supplier relationships, are bound by the same policies and procedures.

South Stream Transport abides by its Corporate Social Responsibility and Sustainability Policy which outlines the Company’s Guiding Principles and commits to applying the principles by: “respecting internationally recognised Human Rights in our own operations, and promoting the respect of the aforementioned rights with regard to activities assigned to or carried out with Business Partners and in our relationships with stakeholders;”

In addition, the Company commits to respecting the UN Global Compact Principles which are “the protection of international human rights; rights to free association, collective bargaining, and employment non-discrimination; protection and preservation of the environment; and elimination of corruption, including bribery and extortion”.

Corporate commitments are contained in the Health, Safety, Security and Environment (HSSE) and Corporate Social Responsibility (CSR) requirements outlined for all contractors and suppliers. This ensures that respect for Human Rights is part of contractual relationships and adhered to in direct business activities.
14.9.3 Labour and Working Conditions

Workers are an important group of stakeholders who may be subject to a range of direct impacts, potentially both beneficial and adverse, in terms of access to employment, the terms and conditions of that employment, and their health, safety and welfare whilst working on the Project.

Considering the Project has a robust Health, Safety, Security and Environment Integrated Management System (HSSE-IMS), the Due Diligence process did not identify any potential impacts in relation to labour and workforce health and safety. Instead, it focused on five primary themes in regards to Project labour and working conditions which, if not properly addressed, could lead to Human Rights impacts:

- Freedom of association and effective recognition of the right to collective bargaining;
- Measures to support a diverse workforce and prevent discrimination;
- Processes and measures to ensure safe working conditions;
- Recruitment processes are fair and transparent; and
- Sufficient processes are in place to ensure no use of forced, compulsory or child labour (either directly or in supply or processing chains).

In order to mitigate for potential risks and impacts on the Project Workforce, it was determined that the Project will adopt the following policies and practices:

1. Human Resources Policy: The formulation and implementation of a Human Resource Policy addressing all the requirements of IFC PS 02 will mitigate these risks (and potential impacts). The Human Resources Policy will be implemented via South Stream Transport’s ESMP (Chapter 22 Environmental and Social Management);

2. Working Relationship: The underlying agreements for all working relationships will be documented by South Stream Transport, and its contractors and subcontractors, and communicated to the Project workforce. All workers will be informed about their working conditions and terms of employment and entitlements to wages and other benefits. All workers will be provided with a written contract containing this information in an appropriate language and/or method;

3. Working Conditions and Terms of Employment: South Stream Transport, and its contractors and subcontractors, will respect the agreed working conditions and terms of employment of the Project workforce (including wages and benefits, hours of work, overtime arrangements and overtime compensation, leave for illness, maternity, public holidays and annual leave);

4. Workers Organisations: South Stream Transport, and its contractors and subcontractors, will allow workers to form and join workers’ organisations of their choosing and to bargain collectively in accordance with Russian national law;

5. Non-Discrimination and Equal Opportunity: South Stream Transport, and its contractors and subcontractors, will base the employment relationship on the principles of equal opportunity and fair treatment and ensure that no employment decisions (including those related to recruitment and hiring, compensation, working conditions and terms of
employment, access to training, job assignment, promotion, termination of employment or retirement and discipline) are made on the basis of personal characteristics unrelated to inherent job requirements;

6. Grievance Procedure: South Stream Transport will ensure that a Grievance Procedure for the Project workforce and contractors is implemented (available either directly via South Stream Transport or via contractors) to allow workers to raise reasonable concerns related to working conditions. South Stream Transport, and its contractors and subcontractors, will inform workers about the procedure when they are hired and (again) when they commence work on the Project site or vessels and ensure that the mechanism is easily accessible. The Grievance Procedure will be supported by an appropriate level of management, and address concerns promptly through an understandable and transparent process providing feedback to those concerned without any retribution. Additionally, the Grievance Procedure will not impede access to other juridical remedies or arbitration procedures; and

7. Child or Forced Labour: The minimum age of employment in Russia is 16. In accordance with South Stream Transport’s and its contractors’ and subcontractors’ hazard identification and safety risk management procedures, all parties will ensure that no persons under the age of 18 are employed in hazardous work or in a manner that is economically exploitative, or is likely to be hazardous or to interfere with the child's education or be harmful to the child's health and physical, mental, spiritual, moral or social development. All work of persons under the age of 18 will be subject to an appropriate risk assessment and regular monitoring of health, working conditions and hours or work. Procedures for appropriate risk assessment, regular health monitoring, and for defining working conditions and hours of work for South Stream Transport, contractor and subcontractor employees more generally are addressed in Appendix 15.1 Occupational Health and Safety. South Stream Transport, and its contractors and subcontractors, will not employ forced labour.

14.9.4 Local Communities

To mitigate any potential Human Rights impacts on Local Communities, South Stream Transport has instituted a Stakeholder Engagement Plan as outlined in Chapter 6 Stakeholder Engagement which ensures consultation with Local Communities, as well as implementation of a Grievance Procedure to ensure a timely and appropriate response to concerns by Local Communities and that potential impacts are addressed appropriately.

14.9.5 Supplier Engagement

The Due Diligence focused on the fact that Human Rights impacts can be linked to Project activities as a result of the behaviour of parties with which the Project is associated, not only direct impacts caused by South Stream Transport. This is particularly relevant because construction of the South Stream Offshore Pipeline is likely to be undertaken entirely by contractors and subcontractors. It was therefore determined that there could be a potential risk of harmful child labour taking place within the supply chain if not properly managed.
To avoid potential impacts in the supply chain, all mitigation requirements set out above under Labour and Working Conditions will apply to South Stream Transport’s contractors, subcontractors, and direct supplier requirements. South Stream Transport will also assess its primary supply chain in relation to this issue on an on-going basis.

14.9.6 Security Provision

The Due Diligence process examined several factors associated with security provision following the guidance as set forth in the Voluntary Principles on Security and Human Rights (Ref. 14.70.) It was determined that a risk of conflict could affect the security environment in a manner that might infringe upon the rights of Local Communities given the history of local security forces in Russia. The track record of public or private security providers in Russia in terms of Human Rights is believed to be weak in the area of training.

In order to reduce the risk of human rights abuses against Local Communities by security forces, whether the security forces are directly employed by the Project, contractors or state security forces, South Stream Transport will ensure training for security forces on escalation of force and protection of Human Rights. Furthermore, South Stream Transport will use its contractual process to ensure that provisions are in place for the conducting of background checks on security staff, as well as monitoring of performance.

Policies, plans and procedures to protect the safety and security of the workforce, community and other Project stakeholders, including provisions for ongoing monitoring and auditing, are documented in the Project HSSE-IMS.

14.10 Conclusions

14.10.1 Summary of Impact Assessment

In terms of economic related impacts, the assessment has identified that the Project will result in limited temporary beneficial economic impacts as a result of additional employment and increased demand for goods and services at the local level during the Construction and Pre-Commissioning Phase. In the longer term, it has also identified beneficial economic impacts at the national level associated with an increase in revenues for both the Russian gas industry and the Russian Federal government, due to the increase in Russian gas exports that the Project will enable.

During the Construction and Pre-Commissioning Phase, there is the potential for Low adverse economic pre-mitigation impacts on Shingari and Don Holiday Complexes and the Anapa Resort Town municipal district tourism sector due to potential impacts on the coastal area amenity that may affect customers of tourism businesses in the area, and thereby potentially reduce revenues for tourism-related businesses. However, the implementation of mitigation, including the Compensation Management Framework, would successfully mitigate for financial impacts on any businesses and as a result, it is considered that impacts on any businesses would be Not Significant. There is also the potential for a moderate adverse pre-mitigation impact on the Varvarovka Horse Riding Business, in a worst-case scenario if that businesses’ access to a riding route is interrupted or severed. However if the worst-case scenario does occur, the application
Chapter 14 Socio-Economics

of mitigation including the Compensation Management Framework and Livelihood Restoration Framework, would reduce the impact significance to Low adverse.

The requirement by the Project for land on both a temporary and permanent basis will also result in Low adverse impacts due to the take up of Agrifirm Kavkaz vineyards and associated economic displacement of vineyard activity; however it is considered unlikely that there would be any loss of employment as the vineyard operator is likely to be able to redeploy workers to other areas and tasks within the vineyard. The application of mitigation, including the Grievance Procedure and, if applicable, access to the Compensation Management Framework and Livelihood Restoration Framework would apply. However, it is cautiously considered that the residual impact would remain unchanged; i.e. a Low residual impact, owing to the vulnerability of the migrant workers and the nature of the process required to restore livelihoods to pre-impact levels, should that be necessary. However, it is important to note that, based on the assessment of impact magnitude, it is not anticipated that there will be any economic displacement of agricultural workers (migrant or otherwise) as a result of the Project.

With regard to community-related impacts, the construction of the Project may result in Low adverse residual impacts on the amenity enjoyed by recreational users of Sukko and Shingari beach, and also on the amenity experienced by visitors to the Varvarovka village cemetery. During the Construction and Pre-Commissioning Phase, residents of north-east Varvarovka that are proximate to the Varvarovka Bypass Road would experience noise and visual impacts; giving rise to overall adverse impact on their amenity. Mitigation measures specific for these impacts have been identified in Chapter 10 Noise and Vibration and Chapter 13 Landscape and Visual. However, given these mitigation measures have been taken account of in the amenity assessment, it is expected that the residual amenity impact would remain Moderate adverse, short term and temporary.

During the Operational Phase, there would be beneficial economic impacts at the national level in terms of increased demand for Russian goods and services (gas) and increased government revenues, taxes and royalties. There would not be any adverse socio-economic impacts associated with the Project during the Operational Phase.

With regard to Human Rights, there were no significant adverse potential impacts identified that cannot be mitigated through adherence to policies, plans and procedures, as well as through community engagement. Human rights issues within the supply chain will be monitored on an ongoing basis which is provided for in the Project HSSE IMS. Furthermore, the Due Diligence process recognises that the Human Rights risks may change over time as the Project evolves from the Construction and Pre-Commissioning Phase into the Decommissioning Phase. As such, the Project’s Human Rights Due Diligence is an iterative process whereby business operations and operating context will be examined on a regular basis.

14.10.2 Overview of Mitigation Measures

This assessment has set out recommendations for mitigation measures. The measures include:

- A range of construction management and environmental and social management processes and procedures to avoid, or where avoidance is not possible, minimise the potential for
adverse impacts, including amenity-related (e.g. air quality, dust, noise, vibration and visual) impacts;

• Ongoing stakeholder engagement, including regular community liaison, during construction of the Project to inform and update stakeholders about planned construction activities and the construction programme;

• A Grievance Procedure to allow for prompt, transparent and satisfactory handling of grievances raised by stakeholders, including from within the Local Communities and the Project workforce;

• Appropriate compensation mechanisms, including within the Compensation Management Framework, to compensate businesses, land owners, and other potentially affected stakeholders for any reduction in business revenues or economic losses that arise as a result of the Project; and

• Appropriate livelihood restoration mechanisms, if necessary, included within the Livelihood Restoration Framework, to restore livelihoods to their pre-impact status.

14.10.3 Stakeholder Concerns and Community Investment Programme

Stakeholders have expressed a range of concerns related to the construction and operation of the Project, including concerns related to traffic, the environment, and economic opportunities. The mitigation measures described in this chapter (and in the chapters addressing other types of impacts) are intended to minimise or avoid potential adverse impacts of the Project, and to enhance local benefits. South Stream Transport will implement the measures necessary to reduce adverse impacts as much as practicable, and to enhance benefits, throughout the life of the Project.

It is not possible to address all stakeholder perceptions and concerns within the scope of the ESIA Report. Some concerns fall outside the scope of the Project’s influence, such as gas supply, community development, and political or regulatory concerns. However, there may be ways in which South Stream Transport can support positive changes and initiatives in Local Communities beyond the immediate scope of Project impacts. To this end, South Stream Transport has a Community Investment Programme, and will work with local stakeholders and agencies to identify potential themes and initiatives for investment. Although potential areas for Community Investment are not included in the assessment of this ESIA Report (i.e. they are not considered to be ‘mitigation’ measures), they may complement or build upon Project-specific mitigation measures, as well as existing programmes and initiatives in the Local Communities. Community Investment activities will be developed and implemented in consultation and partnership with the relevant stakeholders.

14.10.4 Conclusions

The mitigation measures identified are intended to systematically avoid and reduce the potential for adverse impacts associated with the Project, or where this is not possible to compensate for adverse impacts on receptors. Assuming that the mitigation measures suggested in this assessment are successfully implemented, it will be possible for the Project to mitigate
significant adverse effects associated with the Project to the degree that all adverse impacts after mitigation would be **Low or Not Significant** with the exception of short term and temporary impacts on the amenity of residents in North East Varvarovka with a **Moderate** impact.

15  Community Health, Safety and Security

15.1  Introduction

This chapter presents the potential community health and safety impacts arising from Project-related activities, as well as Project security as it pertains to communities. This chapter forms part of the Environmental and Social Impact Assessment (ESIA) Report of the South Stream Offshore Pipeline - Russian Sector ('the Project') that will form part of a system to deliver natural gas from Russia to the countries of central and south-eastern Europe.

This community health, safety and security chapter considers the potential health impacts to national, regional and local population groups, including particularly vulnerable groups who may be disproportionately affected. The approach has been guided by applicable legislative and policy requirements along with relevant guidance including the International Finance Corporation (IFC) guidance on Health Impact Assessment (HIA) (Ref. 15.1) and Good International Industry Practice (GIIP). For example, the approach addresses the two key characteristics required by the IFC guidance, namely: predicting the consequences of project-related actions; and providing information that can help decision makers prioritize prevention and control strategies throughout the project cycle. This has been achieved through: a scoping exercise examining the potential impacts of Project activities; a review of existing baseline health and safety conditions and key trends; evaluation of community views from stakeholder engagement and a health assessment to classify potential health risks before and after the application of mitigation measures.

This chapter has been prepared alongside other assessments that make up the ESIA Report. Where appropriate, this assessment has used relevant data or modelling from other ESIA chapters, as well as information from consultation findings as described in Section 15.4.3.

The consideration of the potential health impacts to the Project’s workforce and the regulatory framework that governs safe working practices is assessed in Appendix 15.1 Occupational Health and Safety. An alternative approach has been taken for occupation health and safety which recognises that throughout the Project the workforce will be exposed to a number of different hazards and associated risks. The occupational health and safety issues identified in the scoping stage have been grouped against global accident data categorisations. The occupational health and safety assessment in Appendix 15.1 discusses these categories with Project-specific links where appropriate. Occupational health and safety mitigation considers the due diligence requirements that the Project will need to meet. This more strategic approach for occupational health and safety reflects that the detailed occupational health and safety regulatory regimes will properly be addressed through Project and contractor management plans and systems.

15.2  Scoping

A general Scoping Report for the international ESIA process for the Project was disclosed in Russia in November and December 2012. Disclosure of the report was followed by a series of meetings with a range of stakeholders in December 2012 including Local Communities, local
non-governmental organisations and local authorities. A number of comments regarding community health and safety were made during this period (see Section 15.4.3) and these informed the subsequent health studies and the content of this chapter.

An internal Health and Safety Scoping Assessment Report (Ref. 15.2) was prepared in 2013 to focus on community health, safety and security issues which, following IFC standards and guidance, more specifically identified sources of exposure and risk for communities and workers during the various phases of the Project. A discussion of the issues considered and the scoping rationale for including or excluding each issue from the main assessment are contained in the Health and Safety Scoping Assessment Report, which has informed this chapter, including Table 15.12. An outline of the issues which are referred to in other chapters is summarised in Section 15.7 and described in Table 15.12. The issues scoped in are discussed throughout the remainder of this chapter.

15.2.1 Issues and Population Groups Scoped In

The scoping stage examined the ways in which the construction, operation and decommissioning of the Project may affect community health, safety and security. Issues identified as having the potential to give rise to community - and population - level health impacts have been taken forward for further assessment. The scoping exercise included:

- Identifying legislative requirements;
- Gathering and reviewing relevant Project information;
- Evaluating health context, including consideration of: location; climate; endemic diseases; and in-migration;
- Reviewing Project design, including consideration of: water bodies; roadways; pipelines; operational facilities; sources of potential exposure; and transmission-line corridors;
- Identifying potentially impacted geographic areas and potentially affected communities;
- Identifying key stakeholders;
- Setting the geographical, time scale, and population boundaries of the assessment;
- Determining the assessment approach; and
- Collecting baseline data including:
  - Evaluation of existing Russian publication data;
  - Evaluation of data from key stakeholders; and
  - Evaluation of data from other ESIA Report chapters.

In determining the potential health impacts of the Project, the scoping exercise used the World Health Organization's (WHO) definition of health: ‘Health is a state of complete physical, mental and social well being and not merely the absence of disease or infirmity’ (Ref. 15.3). Factors that affect health are called the ‘determinants of health’. The IFC defines these as: ‘individual; social and environmental; and institutional factors, which are directly, indirectly, or cumulatively affected by the proposed project’ (Ref. 15.1).
The scoping exercise uses the four ‘determinants of health’ themes (individual, social, environmental and institutional factors) (see Section 15.7.2 and Table 15.7 for further detail) to provide a practical framework in which to summarise the areas scoped in for further assessment. The issues scoped in for further assessment are listed below under the remaining headings. These are the issues that form the focus of the community health, safety and security assessment. The brackets after each issue identify whether the effect falls primarily during the Construction and Pre-Commissioning Phase [construction] or the Operational (including Commissioning) Phase [operation]. For information on the approach to the Decommissioning Phase [decommissioning] see Section 15.8.3.

**Social factors**
- Conduct of workforce in the community [construction];
- Spread of sexually transmitted infections (STIs) due to in-migration of non-local workers [construction];
- Employment opportunities for the local population [construction];
- Public anxiety over large volumes of gas close to Local Communities [operation]; and
- Benefits to the Russian economy from increased gas sales [operation].

**Environmental factors**
- Construction noise impacts from vehicles, plant and vessels [construction];
- Road transport impacts, particularly heavy goods vehicles (HGVs) [construction]; and
- Mobilisation of historic seabed pollutants during trenching and tunnelling [construction].

**Institutional factors**
- Local health and emergency service resources due to in-migration of non-local workers [construction].

**Unplanned events**
- Uncontrolled gas release from pipeline or onshore facilities [operation].

**Cumulative impacts**
- Russkaya CS construction impacts occurring in tandem with this development [construction]; and
- Future development plans in Varvarovka being affected by exclusion zone restrictions [operation].

The assessment uses the following population age categories when scoping potential health impacts:
- Children and infants < 5 years (childhood illnesses);
- Children ages 5-14 years (older childhood, adolescent health effects);
• Women of reproductive age;
• Adults ages 15-64 (working adults); and
• Elderly > 65 years.

15.2.2 Issues Scoped Out during the Assessment Stage

In addition to the issues which have been addressed in other chapters (Section 15.8), there are two issues (air quality and historic ground contamination) which were initially scoped in to the health assessment but were later scoped out on the basis that no significant impacts were expected at the pre-mitigation stage. The following paragraphs summarise the scoping rationale for this decision.

Air quality impacts from vehicles, plant and vessels

Chapter 9 Air Quality determined that the Pre-Commissioning and Construction Phase of the Project will result in the majority of the Project’s emissions and therefore have the greatest potential to affect air quality. Air quality emissions from construction plant, vehicles and materials (including activities related to landfall construction) have potential health impacts. The baseline notes that in Krasnodar Krai, specifically Anapa, Varvarovka and Gostagaevskava, the issue of air pollution is a priority problem for public health, and thus onshore community receptors should be considered. In addition, the issue of dust from increased traffic due to Project activities was raised by stakeholders during EIA disclosure in May 2013 (Ref. 15.4) (see Section 15.4.3).

The air quality assessment modelling includes impacts at the closest two residential community receptors to the landfall section of the Project and concludes that road movements during construction will not give rise to significant impacts to nearby community dwellings. This includes the area of Rassvet and the M25 junction where the largest predicted change in annual mean pollutant concentrations are predicted to occur. Modelling assumptions indicate that health impacts from increased nitrogen dioxide or particulate matter in Rassvet are unlikely and this issue has not been discussed further in this chapter.

Chapter 9 Air Quality reports findings, based on detailed computer modelling provide a strong argument for concluding that the majority of emissions, including benzene, carbon monoxide and particulate matter, from the Construction and Pre-Commissioning Phase of the Project are Not Significant health impacts to Local Communities. The only emissions requiring further assessment are nitrogen dioxide and sulphur dioxide.

Chapter 9 Air Quality notes that modelled impact for nitrogen dioxide and sulphur dioxide uses a modelled scenario whereby worst case shipping emissions lasting no more than six days at the closest point to shore, have been combined with the most adverse one hour period of meteorological conditions over five complete years. As such, the impact reported is highly unlikely to occur in practice and this potential impact has not been discussed further in this chapter.
Nitrogen Dioxide

Health impacts associated with oxides of nitrogen may be delayed for one to five hours after inhalation and brief exposure to low concentrations can cause adverse health impacts. However, as determined by the air quality assessment (see Chapter 9 Air Quality) the total predicted maximum permissible nitrogen dioxide concentration, including baseline, at the worst affected sensitive receptor, is 158 µg/m³ (0.158 mg/m³). This value is well below the reported threshold for adverse health impacts. Furthermore, the modelling suggests a very low frequency of such events and a temporary duration. Based on these assessment findings impacts from nitrogen dioxide have been scoped out.

Sulphur dioxide

The air quality assessment concludes that for predicted change in 24 hour sulphur dioxide concentrations, under worst case scenarios and IFC guideline standard, there is a residual Moderate significance impact. The assessment notes that the scenario for this impact is highly unlikely to occur in practice and would be regarded as of Low / Moderate significance in the context of Russian national air quality legislation (Chapter 9 Air Quality).

From the air quality assessment the highest predicted sulphur dioxide concentration, including baseline, is a maximum 10 minute concentration of 78 µg/m³ (0.078 mg/m³). This is a third of the concentration required to elicit an adverse health impact (even for a vulnerable individual, such as someone with asthma). Furthermore, the modelling suggests a very low frequency of such events and a temporary duration. Based on these assessment findings, impacts from sulphur dioxide have been scoped out.

Mobilisation of historic ground contaminants during site clearance and trenching^1

Chapter 8 Soils, Groundwater and Surface Water reports potential impacts and mitigations for occupational exposure to ground contaminants during site clearance and ground works. This chapter considers the potential for community exposure to ground contaminants from these activities. The exposure dose will generally be less than that of the workforce due to increased distance from the site of contamination; however, population sensitivities may be higher. Two issues were assessed before being scoped out: background radiation levels and soil contamination. These are discussed in the following paragraphs.

Background radiation

Chapter 7 Physical and Geophysical Environment notes that background radiation levels associated with the terrestrial Survey Area (landfall section) were assessed during surveys carried out in 2010, 2011 and 2013. Results of the radiation surveys indicate that background radiation levels within the terrestrial Survey Area (landfall section) meet the requirements of the Russian Standards on radiation protection. Radiation levels measured in the soils do not pose a

---

^1 Mobilisation of historic seabed pollutants in discussed in Section 15.8.1.2
risk to human health in terms of radiation exposure. Based on these assessment findings, impacts on the community from radiation have been scoped out.

**Soil contamination**

There is the potential for onshore site clearance and ground works to mobilise existing pollutants. Chapter 8 Soils, Groundwater and Surface Water notes that elevated concentrations of contaminants that exceed published standards are known to occur in the soil within the soils Study Area (landfall section) albeit at comparatively low levels. The contaminants locally present in the soil may be harmful to human health under certain exposure scenarios. Chapter 8 Soils, Groundwater and Surface Water has concluded that with the following mitigation, which includes undertaking additional desk studies and intrusive investigations, residual impact on human health from soil-bound contamination is **Low**. The assessment includes the provision that:

- In the event that previously unidentified contamination is encountered during construction, works in the affected area will cease and appropriate steps will be taken in accordance with the Contractor’s Contingency Plan, developed as part of the Contractor’s Emergency Response Plan.

Based on these assessment findings, the mitigation related to soil contamination and as the Project includes appropriate dust control measures (see Chapter 9 Air Quality), it is unlikely that community impacts would arise. This issue has therefore been scoped out of further assessment in this chapter.

### 15.3 Spatial and Temporal Boundaries

#### 15.3.1 Project Description

A detailed description of the Project is provided in Chapter 5 Project Description. A brief description of the elements of the Project relevant to this community health, safety and security impact assessment is provided here.

#### 15.3.1.1 Construction and Pre-Commissioning Phase

This phase will involve construction and pre-commissioning activities, which will be undertaken after each of the four pipelines has been installed to ensure that the pipelines meet operational requirements. Key features and activities include:

- Increase in non-local labour (i.e. in-migration from outside the area);
- Temporary and permanent land take within the landfall section construction corridor;
- Construction plant and vehicles operating within the landfall section;
- Vessels in nearshore waters, including an exclusion zone; and
- Dredging and seabed disturbance in nearshore waters.
Works within the landfall section of the Project are expected to last 27 to 30 months, works within the nearshore section are also expected to last for approximately 15 months, and works within the offshore section are expected to last for approximately 3.5 years.

15.3.1.2 Operational Phase

The Project will have an operational design life of 50 years. Key features and activities include:

- Permanent, usually unstaffed, landfall facilities with the capacity for occasional gas venting;
- Permanent Right of Way (RoW) over the pipeline land route;
- Permanent access road to the landfall facilities;
- Reinstatement of other areas to their former uses, but with development restrictions based on the established safety exclusion zones; and
- At sea, the establishment of a safety exclusion zone 500 m either side of the pipeline will preclude fishing within that zone.

15.3.1.3 Decommissioning Phase

The approach to decommissioning, including whether the pipeline will be removed will be determined nearer to the time of decommissioning when more is known about the technologies available to undertake the works and any changes in the sensitivity of surrounding communities. See Section 15.8.3 for further discussion.

15.3.2 Project Location

The Project comprises three sections – landfall, nearshore and offshore. Further information explaining the extent and nature of each section is given in Chapter 1 Introduction. The Project phase timeframes are set out in Chapter 5 Project Description.

Figure 15.1 shows the Russian national level and the Krasnodar Krai boundaries. The Figure also shows boundary of the ART municipal district and location of Local Communities Varvarovka, Sukko, Supsekh, Rassvet and Gai Kodzor; and the town of Anapa.

15.3.2.1 Study Area

The Study Area, for the purposes of the community health, safety and security assessment, encompasses the areas described in Chapter 14 Socio-Economics. In summary, on land the Study Area included the area within 2 km of the landfall section of the Project and also within a 300 m zone either side of potential (existing) access routes. Offshore, the Study Area was based on a 1 km wide zone following the nearshore and offshore route of the pipeline, ending at the EEZ border between Russia and Turkey; this is the area in which the construction vessel spread will operate.

The exception is where the Study Area is extended to that adopted in other chapters of the ESIA Report where those assessments and their respective receptors are discussed.
15.4 **Methodology and Data**

The baseline has drawn on a variety of sources, including published scientific literature, international health and safety organizations, and general literature searches using Internet search engines and standard textbooks of public health. A variety of secondary health status data sources were used for the Russian Federation, Krasnodar Krai and ART municipal district.

15.4.1 **Primary Data and Surveys**

Primary baseline data collection was undertaken to inform the socio-economic impact assessment (see Chapter 14 Socio-Economics) and the information gathered was analysed to ensure that any health related issues were captured and included in this community health, safety and security impact assessment. In addition, specific health related information was sourced from the ART Municipal Administration in March 2013 and February 2014 to inform the community health, safety and security baseline (Refs 15.5 and 15.6) (see Section 15.4.3).

Local officials at the Anapa Resort Town Municipal District Administration (Ref 15.7) and the Gai-Kodzor Rural District Administration (Ref 15.8) provided information in February 2014 related to health facilities in Local Communities which helped inform the baseline (see Section 15.5.3.3). This included information on emergency services, the capacity of local health services and road traffic impacts and road safety issues, specifically in the communities of Rassvet and Gai-Kodzor (Ref 15.8). Information on traffic levels and road safety was also obtained from an interview with the Head of the local school in Rassvet (Ref 15.8).

Data on existing traffic levels was obtained through surveys of potential access roads. The traffic surveys focused on the two most likely approach routes to the landfall site, namely the main roads passing through the communities of Rassvet; Gai Kodzor; Supsekh and Varvarovka. An explanation of the survey methodology, access roads, locations of traffic surveys and the survey results are contained in Appendix 9.1 Traffic and Transport Study.

15.4.2 **Secondary Data**

The main sources of secondary information were:

- Request No. 543 of 01.02.2012 for morbidity and mortality of the adult, adolescent and juvenile population based on data of the State Public Healthcare Institution Medical Information-Analytical Centre of the Department of Public Health of the Krasnodar Krai (GUZ MIATs), during the period 2006-2010 (Ref. 15.9);
- Statistical guide Health and Healthcare in Krasnodar Krai 2012 of the Ministry of Health Krasnodar Krai (Ref. 15.10);
- Report on sanitary-epidemiological situation and consumer rights 2012 Krasnodarsli Krai Ministry of Health of Krasnodar Krai website (Ref. 15.11); and
- National Priority Project Health Implementation in Krasnodar Krai 2007-2011 (Ref. 15.12).

15.4.3 Stakeholder Engagement

Stakeholders are individuals, groups or organisations potentially affected by a project, interested in, or with influence over, a project. Stakeholder engagement provides one part of the process for identifying a list of health issues for analysis.

During scoping consultations, stakeholders raised about the issue of noise and vibration from construction activities\(^2\), and the potential impact on Local Communities. Stakeholders also raised the issue of increased traffic during construction and asked whether any additional roads will be constructed.

A meeting was held with ART Municipal District Administration in March 2013 (Ref. 15.13), including with the ART Municipal District Administration Deputy Chief for Health. At that meeting it was confirmed that during the peak season, extra resources including staff (doctors, paramedics, etc.) are mobilised and clinics operate longer opening hours to deal with increased demand arising from the increased number of tourists in the area. It was also confirmed that the local health services offer free medical services to Russian citizens whether or not they are based in the district.

Local officials at the Anapa Resort Town Municipal District Administration (Ref 15.5) and the Gai-Kodzor Rural District Administration (Ref 15.8) provided information in February 2014 related to local health facilities in Local Communities\(^3\). They reconfirmed that during the tourist season, the numbers of tourists visiting the area means that a range of extra staff and services are provided by the Administration during this time. Emergency facilities are available in Anapa. For more complex cases, patients are transferred to the city of Krasnodar.

The opinion of the Municipal District Administration is that the Project workforce would not unnecessarily strain the local health services as a result of planned Project activities. The needs of any Project related workforce are not expected to compromise the health service provided to tourists and residents during the holiday period (Ref 15.5). In addition, their view is that the services are adequate all year round to cope with the expected numbers of workers related to the landfall section of the Project that are likely to be housed in the area. Further details of the Project stakeholder engagement can be found in Chapter 6 Stakeholder Engagement.

15.4.4 Data Assumptions, Limitations and Gaps

The data used in the community health, safety and security baseline has not been assessed for bias or other limitations in its primary collection methodology.

\(^2\) Stakeholders raised these issues also in relation to the construction of the Russkaya Compressor Station – see Appendix 20.1 Environmental Impacts of Associated Facilities: Russkaya CS.

\(^3\) In addition to the comments in the text, the Administration noted that although they did not have a concern regarding strain on local health facilities in relation to the Project workforce, they are investigating the purchase of mobile health units in order to better service some of the areas outside the town of Anapa.
For some indicators there are no exact definitions, which make the interpretation of the data difficult.

It is noted that in all countries (not just Russia) there is frequent underreporting and misreporting of disease burdens.

Very limited or no data was available for the Local Communities located near the landfall section of the Project. It has therefore been assumed for the purposes of this assessment that the health status in these communities is similar to the ART municipal district within which they are located. It is also assumed for the purposes of this assessment that the Project workforce will be housed in the town of Anapa. This is based on the consideration that it is the town of Anapa, rather than the Local Communities, that is most likely to have a sufficient supply of suitable accommodation options available for requirements.

Given the lack of available local data on health and the lack of specifics at the time of writing in relation to Project workforce accommodation options, the Project will require its contractor to undertake a Rapid Health Appraisal in the pre-construction phase to further understand health conditions (such as disease prevalence) in the Local Communities and including the quality and quantity of local health services. The appraisal will assess the preferred option for the landfall section workforce accommodation, once it is known, as well as potential health impacts relating to the offshore workforce interactions with the town of Anapa and the Local Communities during transit periods. The appraisal may include consultation with applicable local and regional authorities, including health and social service providers.

15.5 Community Health, Safety and Security Baseline

This section provides a summary of the baseline community health, safety and security characteristics of the Project Area.

15.5.1 Demographic Community Profile

The population of ART municipal district was 153,900 people in 2013 (Ref. 15.17). Of these, 40% are urban residents and 60% live in rural areas. Among the entire resident population, men account for 47% and women 53%. The female population of child bearing age accounts for 48.2% of the total female population. Children aged 0 to 17 years account for 19.1% of the total population. Adults (17+) account for 80.9% of the total population. In total, 60.5% of the population are working-age persons and 22.6% are retired (Ref. 15.9).

In the ART municipal district, the birth rate was consistently higher and the death rate was consistently lower than in Krasnodar Krai and the Russian Federation over the period from 2006 to 2010. As a result, and in contrast to the national and regional level indicators, the ART municipal district has had positive net natural population growth since 2007.

At the same time, the ART municipal district has experienced positive net migration at a rate two to three times that of Krasnodar Krai. The main factors contributing to migration growth are the in-migration of non-local labour for the construction, tourism and agricultural sectors as well as a relocation programme run by the Russian military to resettle service personnel to the area.
on retirement. Together, these factors have contributed to the relatively strong population growth in ART.

In 2010, in Krasnodar Krai, the life expectancy for men was 65.8 years and the life expectancy for women was 76.5 years. Since 2003, there has been an increase in life expectancy in Krasnodar Krai, in particular in the period 2006 to 2010.

Life expectancy depends on the mortality rate and 60% of mortality rate in Krasnodar Krai is associated with social factors, healthcare, alcohol and smoking. Smoking accounts for a reduced life expectancy of 19 to 23 years and alcohol use for a reduction of 20 to 25 years, particularly for men (Ref. 15.9).

The infant mortality rate in Krasnodar Krai was reported to be 6.0 per 1,000 individuals in 2011. The infant mortality rate in ART municipal district was 3.4 per 1,000 individuals in 2011 and is lower than the comparable rate for Krasnodar Krai. The infant mortality indicator is considered to be a very sensitive indicator reflecting the socio-economic status of the population and the quality of health services provided (Ref. 15.10).

The perinatal mortality rate in the Krasnodar Krai region has decreased from 6.3 per 1,000 individuals in 2007 to 5.4 per 1,000 individuals in 2010. The maternal mortality rate has increased from 12.1 per 1,000 individuals in 2007 to 15.29 per 1,000 individuals in 2011 (Ref. 15.10).

The number of reported abortions before week 28 of pregnancy decreased in ART municipal district from 43.9 in 2007 to 27.8 in 2011. This was higher than the corresponding figure for Krasnodar Krai – respectively 34.0 in 2007 and 20.22 in 2011.

15.5.2 Known Community Issues

15.5.2.1 Mortality by Disease

Cardiovascular diseases were the leading cause of mortality in 2011 for Krasnodar Krai:

- 58.4% - cardiovascular diseases, (794.7 per 100,000 individuals);
- 15.3% - neoplasms, (20.5 per 100,000 individuals);
- 8.1% - injuries and poisoning, (109.7 per 100,000 individuals);
- 4.5% - a disease of the digestive system (61.3 per 100,000 individuals);
- 3.4% - respiratory diseases (46.3 per 100,000 individuals); and
- 1.7% - infectious and parasitic diseases (22.4 per 100,000 individuals).

Mortality from all causes declined in the Krasnodar region in 2010 by 0.7%, but remained high at 36% above the target of the national priority programme "Health", which aims to improve quality of healthcare through a focus on primary care, prevention and improved access to innovative technologies (Ref. 15.10).

Deaths from diseases of the circulatory system at 794.7 per 100,000 population in 2011 are two-fold higher than the target of 400 per 100,000 population.
Deaths from injury and poisoning were 109.7 per 100,000 population in 2011, which is 9.7% over the target of 100 per 100,000.

From data on implementation between 2007 and 2011 (Ref. 15.10), according to the ranking applied in the report on the Ministry of Health of Krasnodar Krai, ART municipal district is placed as follows for the indicators (some indicators are per 1,000 population, others per 100,000):

- Total mortality - in the lowest range between 11.5 to 13.4 per 1,000 population (the highest rate in the region is 17.6);
- Mortality by cardiovascular diseases - in the lowest range 539 to 740.6 per 100,000 population (highest 1059.3);
- Mortality by trauma and poisoning - in the middle level 106.6 to 133.5 per 100,000 (lowest 75.3 and highest 152.3);
- Mortality by suicide - in the lowest range 8.8 to 20.6 per 100,000 (highest 54);
- Mortality by murder - in the middle range 8 to 15 per 100,000 (highest 22.3);
- Mortality by alcoholism - in the middle range 41.5 to 75.4 per 100,000 (lowest 4.8, highest 113); and
- Mortality by tuberculosis - in the lowest range 9.8 to 20.3 per 100,000 (lowest 2.5, highest 40.7).

### 15.5.2.2 Morbidity, Incidence and Prevalence of Disease

The statistical data demonstrates an increase of incidence and prevalence of diseases among the total population respectively from 560.6 per 1,000 individuals in 2007 to 624.27 per 1,000 individual in 2011 and from 1,160.02 per 1,000 individuals in 2007 to 1242.81 per 1000 individuals in 2011.

</table>
Any changes in the incidence of a particular disease could be explained by a corresponding change in risk factors pertaining to that condition. It could also be explained by a change in diagnostic methods or changes to the ways on which the disease is registered.

**Prevalence of diseases by main types of illness for children**

In the structure of morbidity, the leading cause in both Krasnodar Krai and ART municipal district for children are respiratory diseases, followed by diseases of the digestive system. Eye diseases and infectious diseases in ART municipal district rank third and fourth. Diseases of the nervous systems, dermatologic diseases and musculoskeletal diseases are the next leading causes of morbidity in Krasnodar Krai.

For children the prevalence of all diseases in ART municipal district decreased from 2006 to 2008 and after a small increase, it remained at lower levels than the prevalence reported for the same period in Krasnodar Krai.

The prevalence of respiratory diseases has increased in ART municipal district since 2008 and in 2010 became higher than in Krasnodar Krai for children.

**Figure 15.2 Prevalence of Diseases by Main Types of Illness for Children Aged 1-14, per 1000 Population in Krasnodar Krai (Ref. 15.9)**
Prevalence of diseases by main types of illness for adolescents

For the age group 15 to 17 years, the prevalence of diseases increased during the period 2006 to 2010 in both Krasnodar Krai and in ART municipal district, but in ART municipal district levels are lower. As with the younger age group, the leading cause of morbidity in both Krasnodar Krai and ART municipal district is respiratory diseases.
Prevalence of disease by main types of illness for adults

In ART municipal district, there was an increase in prevalence of all diseases for the age group 18 years and over between 2006 and 2010, at which point the prevalence reached the same levels as Krasnodar Krai. In ART municipal district, respiratory diseases are the leading cause of morbidity in adults, while in Krasnodar Krai the leading cause is circulatory disease.
Prevalence of infectious and parasitic diseases

In ART municipal district, the leading cause for infectious and parasitic diseases is the acute intestinal diseases of unknown causes, while in Krasnodar Krai this is chickenpox. The incident rates of infectious diseases specific to Local Communities were not available for this assessment.

Figure 15.7 Prevalence of Disease By Main Types of Illness for Adults aged 18 and Over per 1000 Population in ART Municipal District (Ref. 15.9)

Figure 15.8 Prevalence of Infectious and Parasitic Diseases (including chickenpox) per 100,000 Population in Krasnodar Krai (Ref. 15.9)
In 2011, Krasnodar Krai achieved a reduction in 40 types of infectious and parasitic diseases. The most significant reductions occurred in:

- Acute hepatitis A by 75% (compared to 33% reduction in Russian Federation);
- Acute viral hepatitis B by 49% (compared to 21.3% in Russian Federation);
- Viral hepatitis C by 45% (compared to an increase in the Russian Federation);
- Scarlet fever by 66% (compared to an increase in the Russian Federation);
- Bacterial dysentery by 31% (compared to 22.1% in the Russian Federation);
- Acute intestinal infections of unknown aetiology by 14% (the same level in the Russian Federation); and
- Newly diagnosed with syphilis by 19% (compared to 13.9% in the Russian Federation) (Ref. 15.9).

**Prevalence of Sexually Transmitted Infections**

**Syphilis**

Syphilis is recorded in the whole of the Krasnodar region. The incidence of syphilis in the past ten years has tended to decline. In 2012, the Krasnodar region recorded 1,474 cases, (28.32 per 100,000 population), including 32 cases of children up to 17 years (3.21 per 100,000 population). The new cases were recorded among all age groups of the population. The incidence of syphilis in urban population is 63.7% of the total (Ref. 15.9).

There is an inconsistent declining trend of incidence of this disease from 45.6 per 100,000 population in 2007 to 34.3 per 100,000 in 2011.
Chapter 15 Community Health, Safety and Security

Gonorrhoea

In 2012, in Krasnodar Krai the incidence of gonorrhoea decreased by 13% compared to 2009, including among children by 24.5%. During the reporting year 2012, 868 cases were registered, which corresponds to an incidence rate of 16.68 per 100,000 population compared to 14.89 per 100,000 population in 2011 and 17.78 per 100,000 population in 2010 (Ref. 15.9).

There is no stable trend in the incidence of this disease in ART municipal district. The incidence varies during the years from 12.1 per 100,000 population in 2007 to 14.9 per 100,000 in 2011.

HIV / AIDS

Currently, in the Russian Federation and in the Krasnodar region, human immunodeficiency virus (HIV) is spreading among the population. In 2012, there were 12,149 registered HIV-infected citizens of the Russian Federation, of which three were children under 17 years. In 2012, there were 1,469 cases of HIV-infected persons in the Krasnodar region (of which 52 cases were in ART municipal district). This is 23% higher than in 2011 (1,131 cases in 2011 and 1,031 cases in 2010) (Ref. 15.14).

In ART municipal district, an increase in incidence of HIV / AIDS (acquired immunodeficiency virus) was observed from 32 per 100,000 in 2010 to 35 in 2011, as well as in prevalence rates from 22.9 per 100,000 individuals in 2010 to 23.7 per 100,000 in 2011. There were three registered cases of pregnant women with HIV / AIDS both in 2010 and in 2011. The prevalence of the disease both in 2010 and in 2011 among women of fertile age is 8.2 per 100,000 individuals.

The main cause of HIV infection in the Krasnodar region, as well as in Russia, continues to be injected drug use and use of non-sterile equipment, accounting for 54.6% of all new infections in 2012. Sexual transmission of HIV continues to increase. Heterosexual intercourse is the main mode of sexual transmission in 2012, accounting for 40.3%. By the end of 2012, the cumulative number of HIV-infected women had doubled compared to 2005 and amounted to 576 (38.6% of all reported cases of HIV infection).

Closely related to AIDS diseases in Russia is tuberculosis (see 15.5.2.3). This disease is the leading cause of death for more than 45% of all HIV cases (due to being immune suppressed by AIDS).

Tuberculosis (TB)

The incidence of tuberculosis shows decreasing prevalence in Krasnodar Krai, as well as in the Russian Federation. The incidence of active tuberculosis in Krasnodar Krai decreased from 62.2 per 100,000 population in 2007 to 52.2 per 100,000 population in 2011. The prevalence also decreased from 183.8 per 100,000 population in 2007 to 147.8 per 100,000 population in 2011. According to a statistical observation in 2012, the Krasnodar region recorded 3,350 cases of newly diagnosed active TB (Ref. 15.10).

The incidence and the prevalence of tuberculosis in ART Municipal District decreased from 2010 to 2011, respectively from 78.7 per 100,000 individuals in 2010 to 50.3 per 100,000 individuals for incidence; and from 173.6 per 100,000 in 2010 to 149.6 per 100,000 for prevalence. With
regard to prevalence of tuberculosis, ART Municipal District falls in the middle range 136.1 to 184.4 per 100,000 (lowest 96.7 to highest 317.0) for Krasnodar Krai.

The mortality from tuberculosis in Krasnodar Krai decreased from 2007 to 2011 from 16.3 per 100,000 population to 10.6 per 100,000 population in 2011. The mortality from tuberculosis in ART Municipal District is 8.9 per 100,000 individuals in 2011 and it is lower than in Krasnodar Krai (10.6 per 100,000 population), but it shows an increase in comparison to mortality levels in 2010 (7.8 per 100,000 individuals).

15.5.2.3 Mental Health

The incidence of psychiatric disorders in ART municipal district increased from 79.2 per 100,000 population in 2010 to 85.3 per 100,000 population in 2011. Psychiatric disorders in ART municipal district are more than threefold lower than in Krasnodar Krai for the same period, respectively 291.7 per 100,000 population in 2010 and 270.7 per 100,000 population in 2011.

The prevalence of mental health disorders in ART municipal district has decreased from 2,415.0 per 100,000 population in 2010 to 2,048.7 per 100,000 population in 2011 and is lower than the reported for Krasnodar Krai which was 3478.2 per 100,000 population 2010 and 3388.6 per 100,000 population in 2011 (Ref. 15.10).

15.5.2.4 Alcoholic Psychosis, Alcoholism, Drug Dependency

There is a decreasing trend in incidence and prevalence of all alcohol and drug related dependency and psychosis in Krasnodar Krai. The available data for ART municipal district for 2011 shows that the levels of alcohol and drug related mental diseases are very close to those in Krasnodar Krai (Ref. 15.10).

15.5.2.5 Traumatism

Traumatism covers injuries caused by external factors. The total traumatism rate in Krasnodar Krai in 2011 per 1,000 population was 78.72 (men 96.98 per 1,000 population; women 64.88 per 1,000 population). In ART municipal district the total traumatism rate in 2011 was 43.54 per 1,000 population (51.46 for men, 36.59 for women) and was significantly lower than for Krasnodar Krai (Ref. 15.10).

15.5.2.6 Invalidity and Temporary Disability

There was a declining trend in primary invalidity in the adult population and in adults of working age in Krasnodar region in the period 2005 to 2010. In 2011, the respective indicators for Krasnodar Krai were: 65.0 per 10,000 people and 47.0 per 10,000 people. In 2011, the primary invalidity in ART municipal district was 76.18 per 10,000 people. It increased from 2010 levels of 75.75 per 10,000 individuals and is higher than the average in Krasnodar Krai.

The invalidity in children (0 to 17 years) in Krasnodar Krai was 19.03 per 10,000 and in ART municipal district 18.85 per 10,000 in 2011. Child invalidity in ART municipal district increased from 127.66 per 10,000 in 2010 to 139.75 per 10,000 in 2011, but remains lower than that in Krasnodar Krai (178.61 per 10,000 population) (Ref. 15.10).
Summary of children’s disabilities (in percentage):

- 37.9% psychiatric diseases;
- 22% neurological disorder;
- 14.2% congenital disorders; and
- 25.9% others.

In 2011, in ART municipal district temporary disability was slightly lower than in 2010. In 2011, the number of lost working days was 259,929 and the total number of cases of disability was 23,280.

Temporary disability in ART municipal district by cause per 100 workers in 2011:

- 19.09 respiratory system;
- 11.29 acute respiratory illness;
- 7.25 musculoskeletal disorders;
- 5.84 cardiovascular;
- 5.37 trauma; and
- 3.7 digestive system illness.

15.5.2.7 Road Safety

National Overview

In 2009, the World Bank issued an analysis of road safety in a number of countries of Europe and Central Asia including the Russian Federation (Ref. 15.44). The key findings, with some recent updates (Ref. 15.50), are still likely to be pertinent in 2013, despite considerable efforts made by Russian authorities to improve road traffic safety.

The key findings for the Russian Federation are summarized here and in Table 15.2. About 72% of all car crashes occur in urban areas. Data for 2008 show that the majority of traffic deaths are among car occupants (52%), followed by pedestrians (36%), motorcycle drivers and passengers (5%), truck and bus drivers and passengers (4%), and cyclists and others (4%). The high percentage of pedestrian deaths in the Russian Federation contrasts sharply with other European countries (in France and Germany, for example, pedestrian deaths account for only 12% of total road fatalities). More than 50% of all road traffic deaths are among people aged 15 to 44, the most economically productive age group. Children and the elderly are also particularly vulnerable, especially as pedestrians.

One-third of car crashes in Russia are caused by speeding vehicles. Head-on collisions due to driving into oncoming lanes are a major cause of road crashes. Drunk driving accounts for 10% of all road crashes in Russia; poor road conditions and traffic management also contribute to road traffic injuries and deaths. The use of cell phones and texting devices while driving is another growing risk factor.
In 2010, the governments of the world declared 2011–2020 as the Decade of Action for Road Safety. They invited the World Health Organization to prepare a report (Ref. 15.45) that provided a baseline to assess the state of global road safety at the onset of the Decade, and to be able to monitor progress over the period of the Decade. The report included a Statistical Annex that provided information that included estimated road traffic death rate per 100,000 population for 182 countries. In terms of the death rate, Russia was ranked 115th. A comparison with other countries that border the Black Sea is set out in Table 15.2.

Regional and Local Road Safety

According to the ranking applied in the report on the Ministry of Health of Krasnodar Krai (Ref 15.10), mortality by transport incidents in the ART municipal district is in the middle range at 19.9 to 29.3 per 100,000 (the lowest in the region is 10.3 and the highest 50.1).

In Krasnodar Krai, since 2006, the number of traffic accidents has fallen; in 2011 there were 6,728 accidents, down 5% on 2006 (Ref. 15.46). In the ART municipal district, in 2011, there were 4,655 traffic accidents and 39 traffic-related deaths (Ref. 15.53).

Table 15.3 shows the number of road traffic deaths in the Russian Federation, Krasnodar Krai and the ART municipal district. For both the Russian Federation and Krasnodar Krai, there was a reduction in road traffic deaths over the period 2007 to 2009, but since then an increase has occurred.

Source: Ref. 14.54; Ref. 14.55; Ref. 14.56; and Ref. 14.57.

Stakeholder engagement (Ref. 15.49) has identified that road traffic and road safety are issues for the Local Community of Rassvet (Ref. 15.48 and 15.49) which is spread either side of a main north-south road. The adjoining small community of Zarya lies immediately to the east. To the west, separated by a thin strip of open land, is the much smaller community of Tarusin. This layout suggests that high traffic volumes could cause community severance. Site visits to Rassvet indicate that there do not appear to be footpaths, cycle lanes, controlled crossing points or other traffic management, as illustrated in Figure 15.10 on the main road through Rassvet which runs from the junction with the M25 (Figure 15.11) towards the community of Gai-Kodzor. It is reported that speeding vehicles are an issue on the road with vehicles travelling at speed on the downhill slope of the road as it runs north from Gai Kodzor into Rassvet (Ref. 15.48) (Figure 15.12). It has also been reported that the community has experienced an increase in road traffic connected to the construction of the Russkaya CS.

Information contained in Appendix 9.1: Traffic and Transport Study and site visits confirm that Rassvet has sensitive receptors that could be affected by traffic increases. Figure 15.10 indicates that there are approximately thirty residential properties lining the road, with additional properties accessed from side roads. Site visits have confirmed that there is a kindergarten, a number of shops and businesses, a post office and a local community centre on the main road through Rassvet. The local school is nearby. Pedestrians walk along the edge of the road. A number of school children cross the main road each day on their way to and from school. All children at the school are regularly trained regarding traffic safety issues (Ref 15.49).

In 2012, the community of Gai-Kodzor was experiencing an increase in traffic related to the construction of the Russkaya CS (Ref 15.51) (Appendix 20.1 Environmental Impacts of Associated Facilities: Russkaya CS). In 2013, a bypass was constructed by Gazprom Invest to allow traffic related to the Russkaya CS construction activities to avoid the community of Gai-Kodzor. In February 2014, the Gai-Kodzor Administration confirmed that the bypass has been effective and road traffic issues related to construction traffic have been resolved (Ref 15.50). The bypass constructed around Gai-Kodzor will also be used by the Project construction traffic in order to avoid road traffic impacts on the town of Gai-Kodzor (Ref 15.56). A similar bypass to avoid passing through the centre of the community of Varvarovka will be constructed and used by Project related construction traffic (see Chapter 14 Socio-Economics).

15.5.2.8 Crime and Security

Table 15.4 shows that over the period from 2006 to 2009, the crime rate in Anapa Resort Town decreased by approximately one quarter. Since 2009, through to 2012, the rate has remained relatively constant. In 2012 a total 1,959 crimes were reported within the ART municipal district, representing an increase compared to the preceding three years (2009 to 2011) but still lower than the annual numbers from 2006 to 2008).
In 2011 and 2012, theft accounted for almost half of total crimes. The second highest ranking type of crime, accounting for approximately one third of crimes in 2012, is crime committed in public (the definition of which includes vandalism, amongst other things).

The highest crime levels are registered during the tourist season (June to September), when the population swells with tourists and seasonal workers. The number of crimes can increase by up to three times during this period compared with the remainder of the year with a focus on theft and other petty crimes; however, there are no incidences of serious disorder. Additional police are brought in from Krasnodar Krai during the summer high season (Ref 15.68).

Although data are not available, interviews with local officials indicated that Local Communities experience relatively lower levels of crime compared with ART as a whole and that crime tends to be concentrated within the town of Anapa rather than within the more rurally located Local Communities (Ref. 15.58).

Source: (Ref. 15.68)
15.5.3 Baseline Data by Determinant of Health

15.5.3.1 Individual Factors

Alcoholism reflects social disadvantage and brings considerable damage to health. On average in Krasnodar Krai, alcohol accounts for 10% of mortality. In some districts this impact can be significantly higher and range from 20 to 30%. In Krasnodar Krai, 50% of mortality is due to interrelated socio-economic factors and alcohol (Ref. 15.9).

For most districts of Krasnodar Krai, the main reason for elevated mortality is alcohol use, together with smoking, low salary and unsatisfactory capacity of the health systems (Ref. 15.9). Health system capacity is an institutional factor which is discussed further in Section 15.5.3.4.

In 2011, the ‘health without smoking’ programme (Ref. 15.15) was implemented in Krasnodar Krai aimed at banning smoking in public places.

15.5.3.2 Social Factors

In the ranking applied by a State Report on Sanitary Epidemiological and Consumer Protection in the Krasnodar region (Ref. 15.9), in 2010 ART municipal district was ranked as follows:

- Salary – in the middle range 13,399 to 17,683 Rubli per person (lowest 11,530, highest 23,144);
- Investment – in the middle range 32,325 to 71,212 Rubli per person (lowest 5,115, highest 264,853);
- Healthcare expenditure – in the middle range 4,339.1 to 5,846.6 Rubli per person (lowest 3,478.8 - highest 9485.8);
- Coverage with physicians per 10,000 population – in the highest range 25.7 per 10,000 – 49.7 per 10,000 (lowest 15.2 per 10,000); and
- Unemployment – in the highest range 1.2 to 1.9% of working population (lowest 0.3%).

Social factors and individual way of life determined more than 50% of the mortality rate (socio-economic more than 20%, healthcare 10%, alcohol 10% and smoking 10%) while the influence of environmental factors is estimated at 10%. This gives a ratio of 5 to 1 for social factors prevailing over environmental factors.

Comparison of socio-economic indicators of well-off and disadvantaged mortality in Krasnodar Krai in 2010 revealed that there is a very high association between the levels of investment in the area and the wellbeing of the population. Coverage by physicians, salary, and healthcare expenditures also play a key role in population wellbeing.
15.5.3.3 Environmental Factors

Air quality

There has been an increase of air pollution between 2000 and 2011 in Krasnodar Krai. ART Municipal District is among the sites with a concentration of air pollutants higher than the permissible levels (Ref. 15.9) (see Chapter 9 Air Quality).

The deterioration is likely linked to the increase in the number of cars in Krasnodar Krai (300 cars per 1000 population or more than 1.5 million cars), which accounts for about 80% of the total emissions from both transport and stationary sources of emission (Ref. 15.9).

The main emission substances measured and controlled on a quantitative basis on the territory of Krasnodar Krai between 2007 and 2011 are nitrogen dioxide, carbon monoxide, sulphur dioxide, hydrocarbons, and formaldehyde (Ref. 15.9).

The results of health risk assessments in Krasnodar Krai indicate the issue of air pollution as a priority problem for public health (Section 15.2). The combined effects of air pollution pose a risk to the body’s systems, including: respiratory, immune, central nervous system, blood, eyes, systemic exposure, development, carcinogenic, nervous system, cardiovascular system (Ref. 15.9). However, as discussed in Chapter 9 Air Quality, the baseline reported concentrations of nitrogen dioxide, carbon monoxide and sulphur dioxide in the Project Area are below the long term and short term Russian limit value and adopted Project Standards. Concentrations of total particulate matter reported for Anapa and Gostagaevskaya are in excess of the long term Russian limit value but below the maximum peak maximum permissible concentrations (MPC) value.

Quality of the Water in the Black Sea

Analysis of the laboratory tests for recreational waters of the Black Sea over the last five years has shown that the sea water quality has improved. The proportion of samples taken to monitor bathing water standards that do not meet regulatory requirements, decreased (Ref. 15.9):

- Chemical indicators from 2.2% in 2007 to 0.2% in 2011; and
- Microbiological indicators from 4.0% in 2007 to 1.8% in 2011.

ART municipal district is one of the cleanest areas with full compliance with Russian water quality standards in 2011 (Ref. 15.9).

Drinking Water Quality

The drinking water supply source for ART municipal district is the Kuban River. The river runs through virtually all of the major population centres of the Krasnodar Krai. The largest share of the contaminants in the river comes from Krasnodar (66%), Armavir (8.6%) and Kropotkin (2.3%). Kuban river waters coming to Anapa are contaminated by micro-organisms, eggs and larvae of worms and protozoa, chemicals (iron, copper compounds, petroleum hydrocarbons, nitrites, nitrogen, organic compounds, chlorine and phosphorus-containing pesticides) (Ref. 15.9).
The quality of drinking water supplied to the distribution networks of the town of Anapa and 13 surrounding communities is monitored by Anapa water utility. Water samples are taken monthly in accordance with the timetable agreed with ART municipal district in accordance with SanPin 2.1.4.1074-01 "Drinking Water. Hygienic requirements for water quality of centralized drinking water supply. Quality Control" (Ref. 15.18).

15.5.3.4 Institutional Factors

As noted in Section 15.5.3.1, for most districts of Krasnodar Krai, one of the contributing factors to elevated mortality is said to be unsatisfactory capacity of the health systems (Ref. 15.9). The consultation feedback from the ART Municipal District Administration Deputy Chief for Health (Ref. 15.13) suggests that the unsatisfactory capacity issues do not extend to ART Municipal District, a conclusion which is supported by the figures reported for healthcare expenditure and coverage with physicians in Section 15.5.3.2.

Health Workforce Capacity

In 2011 the number of doctors per 10,000 individuals in ART municipal district was 34.5. There was a 20% rise in this indicator in ART municipal district in seven years, while in the Krasnodar Krai this indicator fell by 1.6% (Ref. 15.10).

The number of hospital beds in ART municipal district during this period fluctuated slightly and in 2011 was 1,055 units or 68.5 units per 10,000 individuals. The number of hospital beds in the Krasnodar Krai in 2011 was 90.8 for 10,000 individuals (Ref. 15.10).

Based on 2011 data, seven hospitals were operating in ART municipal district (as in 2006), as well as 18 outpatient clinics (the number of these institutions gradually increased between 2006 and 2011) (Ref. 15.10).

Continued...
There was a considerable increase in the number of physicians and secondary medical personnel in ART municipal district in 2006 to 2011; whilst there has not been a significant change in the number of physicians in the Krasnodar Krai region as a whole: it fluctuated within 21,700 to 22,300 individuals. The number of physicians for 10,000 individuals in 2011 is 41.9, which is higher than in ART municipal district (34.5).

The number of physicians in the Russian Federation rises every year with a higher number (51.2 for 10,000 population) compared to ART municipal district and the Krasnodar Krai.

The number of secondary medical personnel has been falling since 2009 in the Russian Federation. In the Krasnodar Krai there are 89 for 10,000 individuals, which is higher than in ART municipal district. In regards to the number of secondary medical personnel in the Russian Federation, there is no general pattern of increase or decrease in this category of individuals and the figure changes every year (Ref. 15.10).

Healthcare Services

According to the data published on the Ministry of Health of Krasnodar Krai website (Ref. 15.17), primary care stations, dental and emergency healthcare facilities ensure access to healthcare for the residents of ART municipal district.

Primary Care

The 17 primary care stations with assistant physicians to provide obstetrics care are listed in Table 15.6.

Complete.
The number of hospital beds, including day care beds in hospitals in the district was 990 in 2013. ART municipal district has a lower number of hospital beds per 10,000 population (61.6) than Krasnodar Krai (average 80.8 per 10,000 population).

**Dental Care**

The Ministry of Health of Krasnodar Krai lists one dental clinic which has 350 visits per shift; no further information on the clinic is provided.

**Emergency Care**

The average of visits per shift for outpatient clinics in the district is 2,880. The average time required for an ambulance to arrive in Krasnodar Krai to the patient in 93.2% of cases was under 20 min.
The total hospital mortality in ART municipal district is 1.21%, which is lower than in Krasnodar Krai (1.38%). The leading causes of hospital mortality are: cardiovascular diseases 55.13%; diseases of digestive system 12.81%; cancer 7.91%; trauma 7.88%; respiratory diseases 4.72%; and infectious diseases 11.55%.

**Indicative Health Performance of ART Municipal District**

The indicative health performance in Krasnodar region includes indicators of medical and social performance, of resource use, and satisfaction from the delivery of health care (Ref. 15.9).

The most problematic indicators reflecting the medico-social performance are the incidence of alcohol psychosis, acute hepatitis and exacerbation of chronic diseases. Other unfavourable indicators are those relating to child and adolescent mortality. These indicators will be influenced by access to health services and also by wider social and economic factors (Ref. 15.12). Despite good coverage with doctors and nurses, the high number of emergency care calls suggests that access to primary healthcare remains a challenge.

To receive specialized high technological medical care the residents of Krasnodar Krai (including ART municipal district) are referred to federal clinics in Moscow, St. Petersburg, Obninsk and Ufa. As a result of the investment made by the national priority project “Health” in Krasnodar...
Krai (Ref. 15.10), the number of residents of the region, who have received high-tech medical services in 2011 increased by 4 times compared with 2006.

The integrated rating for medico-social performance, ‘effective use of resource and satisfaction with medical services’ ranks ART municipal district 17 out of 44 districts. Although ART municipal district is showing a good effective use of resources (10 out of 44) and relatively good medico-social performance (22 out of 44), the population of ART municipal district does not appear to be satisfied by the quality of medical services provided (Ref 15.9).

**Capacity and Type of Local Medical Facilities**

Local officials at the Anapa Resort Town Municipal District Administration (Ref 15.5) provided information in February 2014 related to local health facilities in the Local Communities and in the town of Anapa. The Anapa hospital has over 700 doctors and nurses and 720 patient beds. The ART municipal administration officials stated that mobile health units are needed in order to service the local population outside the town of Anapa.

Due to the Anapa Resort Town area being a tourist destination, provision is made for extra capacity in the summer months to accommodate increasing demand. In each resort area, at least three additional ambulance cars are added during peak season in Anapa. There is an estimated 30 percent increase of staff – including up to 12 doctors working in 3 shifts. At local hospitals, including in the town of Anapa, there are 2 to 4 additional doctors in the peak season. There is a sufficient number of nurses and, if required, medical staff numbers can be supplemented with senior graduates of the local medical college and commercial clinic personnel. Some doctors have medical posts on the beaches which are affiliated with the health sanatoriums in the area. It is viewed by health professionals as prestigious to work in the town of Anapa area due to the high quality facilities, and level of education of personnel.

The hospital in the town of Anapa (which is classified as a trauma two hospital) has specialised units for trauma, cardiology, neurology, blood vessels, infections, general paediatrician, psychiatry, and has x-ray, CAT scanners and other similar level equipment. If the hospital cannot assist patients requiring more specialized treatment, they are sent to Krasnodar, or to the blood vessel centre in Novorossiysk. For eye emergencies, the town of Anapa hospital can provide treatment but eye surgery is deferred to Krasnodar. In Krasnodar, the hospital has helicopter capability (the trip from Anapa to Krasnodar is 40 to 45 minutes), a burn unit and full surgery capabilities (including for heart and joints). There is also a hyperbaric centre in Krasnodar.

During the high season, the most common ailments treated in the town of Anapa hospital include trauma, food poisoning, and head colds. For children, the most common diagnosis is digestion and related food issues, and trauma from a fall or other accident.

In the community of Gai Kodzor there is a laboratory and a physiotherapy room. In the community of Rassvet, there is a medical point with a doctor and nurse on duty although there is no ambulance or emergency facility. The municipal district administration is planning in 2015 to build a general practice in Rassvet for both adults and children.

Ambulances originate from the Anapa emergency facilities or from emergency sub-stations located in the surrounding communities, including Supsekh which is the closest emergency sub-
station to the Local Communities. Patients requiring emergency service are taken to health facilities in the town of Anapa.

15.5.4 Emergency and Disaster Response

Emergency and Disaster Response is discussed in Chapter 19 Unplanned Events. Specifically, South Stream Transport will ensure that contractor Emergency Response Plans appropriately integrate with the Disaster Management Plan for Anapa municipality and the National Disaster Management Plan with regard to command and control systems, points of first contact during emergencies, local capabilities and capacity.

15.6 Legal and Policy Context

The community health, safety and security assessment has considered relevant Russian federal (national) and regional legislation, applicable standards and guidelines for international finance, and international agreements to which the Russian Federation is a signatory. All applicable standards relevant to the ESIA are presented in Chapter 2 Policy, Regulatory, and Administrative Framework, with those of particular relevance to health, safety and security summarised below.

15.6.1 IFC Performance Standards (PS)

Performance Standard 1

PS 1 is addressed across the entire ESIA (see Chapter 2 Policy, Regulatory, and Administrative Framework); however the following points are noted with regard to the community health, safety and security impact assessment. Climate change is included in the consideration of cumulative impacts. The methodology includes stakeholder engagement and assessment of vulnerable groups who may be disproportionately affected (Section 15.4.2). In adopting mitigation measures the mitigation hierarchy has been used (Section 15.10). Emergency response planning is discussed as part of the assessment of resource demands on health and other emergency services.

Performance Standard 2

PS 2 (Ref. 15.18) recognizes that the pursuit of economic growth through employment creation and income generation should be accompanied by protection of the fundamental rights of workers.

The aspects of PS 2 most relevant to occupational health are linked to discussions in the socio-economic assessment which can be found in Chapter 14 Socio-Economics. Chapter 22 Environmental and Social Management also discusses the Grievance Procedure, an important aspect of the management of occupational health and safety issues. Appendix 15.1 assesses the requirements for a safe and healthy work environment and occupational health issues are discussed further within that Appendix and are not addressed further within this chapter.
Performance Standard 3

PS 3 (Ref. 15.20) recognizes that increased economic activity and urbanization often generate increased levels of pollution to air, water, and land, and consume finite resources in a manner that may threaten people and the environment at the local, regional, and global levels.

The following points in relation to PS 3 are noted with regard to the health, safety and security assessment. The assessment takes into consideration the current baseline conditions of affected areas and populations such that impact significance and mitigation measures are sensitive to the level of current environmental degradation. The assessment sections review the potential for pollution, disturbance and resource use to impact human health and where appropriate include technically and financially feasible mitigation measures which aim to avoid (and where this is not possible, minimize) such adverse impacts.

Performance Standard 4

PS 4 (Ref. 15.21) recognizes that project activities, equipment, and infrastructure can increase community exposure to risks and impacts and recognizes the responsibility of the project to avoid or minimize the risks and impacts to community health, safety, and security that may arise from project related-activities, with particular attention to vulnerable groups.

The following points are noted with regard to the health, safety and security assessment in relation to PS 4. The assessment evaluates risks and impacts to the health and safety of Local Communities throughout the Project life-cycle and where appropriate outlines control and mitigation measures consistent with GIIP. The mitigation measures specified in this chapter are commensurate with the nature and magnitude of the impacts that they aim to avoid (or where this is not possible, minimize). The assessments and Chapter 19 Unplanned Events consider community exposure to hazards. Mitigation measures have been included to minimize exposure. The assessment has included consideration of disease associated with water and communicable diseases (including the potential for impacts on vulnerable groups) (See Ref. 15.2 and Section 15.10). Vector-borne diseases were considered but scoped out (see Section 15.8 and Appendix 15.2: Potential impacts discussed in other ESIA chapters and scoped out of the community health, safety and security assessment).

15.6.2 National Legislation

Public Health Policies

National Priority Programme ”Health” (Ref. 15.10) is the overall strategic document at the federal level in Russia until 2020. Its main priorities have been implemented also at the regional level in Krasnodar Krai and include:

- Promoting Healthy Lifestyles – decrease smoking, alcohol use, prevent infectious diseases;
- Strengthening primary healthcare and disease prevention;
- Improving access and quality to specialized and high technology healthcare; and
- Improving maternity and paediatric health care.
Communal Infrastructure

The concept of health risk has been reflected in a number of laws (Ref. 15.22) and regulations (Ref. 15.23 and Ref. 15.24). These include resolutions by the Chief State Sanitary Doctor of the Russian Federation (Ref. 15.25, Ref. 15.26 and Ref. 15.27), which concern sanitary protection zones and classifications.

Risk assessment methodology currently represents the best analytical tool for the characterization of the influence of environmental factors on the health status of the population and is based on criteria that reflects the direct impact of chemicals on the human body. Currently, a health risk is defined as the probability of the threat to life or human health due to exposure to environmental factors. These types of exposures are considered in the assessment.

15.6.3 Regional / Local Policy

Specially Protected Natural Area and Sanitary Control Zones of ART Municipal District

The ART municipal district was designated a health resort town in 1957 (Ref. 15.52) and is designated at a Russian federal level as a specially protected natural area (SPNA) (Ref. 15.53), under the category of ‘health improving (spa) resort area’ known as the Anapa Sanitary Protection Area (SPA) (Ref. 15.54). The Anapa SPA designation entails a series of development control regimes that apply to three different sanitary protection zones (SPZs) within the SPA, the general purpose of which is to protect the area from any activities that may adversely affect the natural therapeutic resources and sanitary conditions of the resort town area (Ref. 15.55).

The three SPZs within the Anapa SPA are:

- Exclusion zone (the first zone of the SPZ);
- Limitation zone (the second zone of the SPZ); and
- Monitored zone (the third zone of the SPZ).

The regime of commercial use and zoning of the territory is determined by the laws of the Krasnodar Krai General Assembly (Ref. 15.28).

The exclusion zone covers territories of mineral waters occurrence on the surface, their withdrawal from wells, locations of therapeutic mud deposits, mineral lakes and coastal salt lakes, which water is used for medical purposes, beaches, and near-shore areas at the distance of 2 nautical miles (3.7 km) from the coast and over 100 m wide territories adjacent to beaches. The territory of the exclusion zone is excluded from any commercial activities not connected directly with studying, use of the natural therapeutic resources of the resort, permanent and temporary residence of citizens, construction of facilities, mining and

---

4 SPNA zones can also be designated for a number of other purposes such as wetlands, protected natural landscape, traditional nature use, national parks, natural moments, etc.
earthmoving operations and other activities that may cause adverse impact on the natural therapeutic resources and sanitary conditions of the resort.

Within the limitation zone it is prohibited to construct facilities and structures, perform earthmoving and mining operations other than directly related to development and improvement of the resort, construct drain wells, arrange irrigation fields and subsurface filtration, cemeteries, cattle breeding complexes and farms, burial grounds for animal refuses, landfills (dumps) for production and domestic wastes' disposal, green plants' felling (except of sanitary felling); use land plots, forest lands and water bodies for any purposes, which may bring to quality and quantity loss of the natural therapeutic resources of the resort.

Within the monitored zone it is permitted to perform all works, which cannot impact adversely on the natural therapeutic resources and the sanitary conditions of the resort.

The territory of ART municipal district also includes the State Natural Sanctuary "Utrish" (SPNA of the federal level) and four SPNAs of the regional level.

- Monument of nature 'Karabetova Gora (hill) with mud volcanos';
- The State Natural Sanctuary 'Krasnaya Gorka';
- Monument of nature 'Zheleznyi Rog Cape';
- Monument of nature 'Panagiya Cape'; and

These SPNA also have a special regime of use.

15.7 Impact Assessment Methodology

The following sections set out the methodology for the community health, safety and security impact assessment. Information within Chapter 5 Project Description (along with other chapters as relevant) and the baseline characteristics provided above have been used to assist the evaluation of the potential impacts and their significance.

15.7.1 Methodology

The impact assessment methodology follows the International Finance Corporation (IFC) guidance on Health Impact Assessment (Ref. 15.1). The IFC guidance stresses that ‘the level of effort to assess health impacts should be proportional to the potential health impacts and risks. It is vital to get a good balance that allows health issues to be integrated into project planning and implementation in a timely and cost-effective manner’.

Most of the guidance provided by IFC is applicable and consistent with GIIP. The main exception is the categorization of environmental health areas which were designed for developing, non-OECD countries. For example, it emphasizes vector borne diseases which have a prevalence rate in Africa but do not have a high prevalence rate in Russia. The categories of environmental health areas mix health outcomes and health determinants. However, the revised guidance does offer an alternative to distinguish environmental, social and institutional determinants of health. This preferred method of categorization has been adopted for this assessment.
The method of prioritization proposed by IFC and which follows GIIP is based on combining probability and severity to assess significance. By contrast, the methodology utilized for this ESIA combines sensitivity and magnitude to determine significance. In practice, neither method is entirely suitable for assigning significance to health impacts and both are difficult to use consistently across all health issues. In many cases, significance is a judgement made explicitly by the assessor and justified with supporting text. It highlights the issues which are priorities for mitigation. The choice of prioritization method does not change that judgement. The use of sensitivity and magnitude to determine significance is therefore seen as an acceptable departure from the IFC guidance on health impact assessment (Ref. 15.1).

The health, safety and security assessment forms part of a prospective process, which means that it is undertaken in advance of the implementation of the Project, thereby providing sufficient opportunity to enable 'constructive modifications' to be made to the Project should negative potential effects be identified and mitigations required. The presumption has been to draw up a wide scope of the potential health issues and potentially affected population groups. This wide scope was then narrowed to those health issues and population groups that are most affected by the Project. These issues and population groups have been assessed, including a classification of the significance of the potential impacts.

The health, safety and security assessment has included consideration of direct, indirect, and cumulative changes in community exposures to environment-based health risks, such as communicable diseases, equipment incidents, and exposure to hazardous materials or conditions.

The health, safety and security assessment has been framed and informed by work undertaken for other parts of the overall Project impact assessment (e.g. air quality and noise modelling) and has taken into account the findings of other chapters to inform the assessment of impacts on human receptors; including but not limited to Chapter 14 Socio-Economics, Chapter 9 Air Quality, Chapter 10 Noise and Vibration and Chapter 13 Landscape and Visual.

The findings of this chapter are also supported by several appendices including Appendix 9.1 and Appendix 14.1 South Stream Offshore Pipeline Fisheries Study. Additionally, this chapter has also referred to Appendix 12.2 Sediment Dispersion Study.

15.7.2 Determinants of Health

As described in Section 15.2, the Project has the potential to affect a broad range of environmental, social and institutional determinants of health either positively or negatively; examples are illustrated in Table 15.7.
Table 15.7 Determinants of Health (Ref. 15.29)

<tr>
<td>High</td>
<td>Groups who share resources constantly with the Project may be more sensitive to its impact. This could include users of roads, tracks, wild foods and marine resources. It could also include those who live adjacent to a Project component such as a busy road. It could include cyclists and pedestrians sharing roads with construction vehicles more than twice per day. Some groups may normally engage in high risk behaviours which make them more sensitive to changes in risk. For example, members of the community who drive dangerously along roads used by construction traffic; those who purchase or provide unprotected sex. Some receptors may anticipate risks to their health and wellbeing and express high levels of anxiety. They are likely to be very aware of actual changes. The technical hazards of a project component may be unfamiliar and poorly understood by a community; and this could increase sensitivity.</td>
</tr>
<tr>
<td>Moderate</td>
<td>Communities with some coping strategies and some vulnerabilities, who are classed as less sensitive than the high sensitivity group. They are likely to experience temporary inconvenience as a result of changes in environmental or social determinants of health. They may share resources occasionally with the project, such as two peak uses of roads each day. They express some concerns and anxieties regarding the impact of the project on their wellbeing. They have some, but not complete, understanding of the technical hazards associated with project components.</td>
</tr>
<tr>
<td>Low</td>
<td>Communities with sufficient coping strategies who feel little or no challenge to their wellbeing as a result of project activities. They may share resources with the project occasionally and broadly understand the hazards associated with project components. Most drivers of private vehicles are in this category.</td>
</tr>
<tr>
<td>Negligible</td>
<td>Communities who do not share resources used by the project and have not raised concerns about potential impacts. They are generally not inconvenienced by project activities or exposed to project-related hazards.</td>
</tr>
</tbody>
</table>

As health impacts may or may not be evenly distributed across the population, the assessment has considered the equity of impacts. Vulnerability is a key consideration within the general discussion of social, environmental, and institutional determinants of health. In many cases, certain subgroups (for example, children, women and the elderly) may be disproportionately affected.

There is also some geographical variation in community sensitivity. The Project is located within an area that is mainly agricultural in nature; the nearest Local Community is Varvarovka, the centre of which is located approximately 2 km northwest of the landfall section of the Project. The other Local Communities are Gai Kodzor, Supsekh, Rassvet and Sukko. The town of Anapa (estimated population 59,000) is the nearest large urban settlement, approximately 10 km to the north of the landfall section of the project. The town of Anapa has been given the status of
a health resort town since 1957 and is a specially protected natural area (SPNA) at the federal level (see Section 15.6.3).

The noise, air quality and socio-economic assessments identified a number of specific residential receptors close to the landfall section of the Project or close to proposed construction access routes that may also be affected by impacts related to community health, safety and security (see Chapter 10 Noise and Vibration).

Not all of the residences are likely to be occupied during the Project Construction and Pre-Commissioning Phase:

- ‘Chateau Club Village’ is a proposed residential development covering an area of approximately 69 ha located on the north-eastern edge of Varvarovka, just outside of the officially designated boundary or urban limit of the community. The proposed Varvarovka bypass road for the Project passes partly along the edge of and partly through the middle of the proposed development. This development has been placed on hold as an agreement has been concluded with the developer to use the road through the site as a temporary access road (i.e. for the Varvarovka bypass road) (Ref 15.57).

- Receptor 5: The closest residential receptor to the landfall facilities (excluding the access roads) is the Clearing in the Woods (“Lesnaya Polyana”) development which is just beyond the outermost exclusion zone (Exclusion Zone 3 / A-class). Lesnaya Polyana is divided into approximately 160 plots, varying in size from 600 m² to 1,700 m² (Ref. 15.39). Some internal infrastructure has been completed, however, the date when dwellings will first be occupied is not clear and it has been assumed, for the purposes of this assessment, that the development will not be occupied prior to the completion of the construction of the landfall section of the Project.

As the noise and air quality assessments have also found that all impacts during the Operational Phase are Not Significant, the above, currently unoccupied receptors, are not considered further in this assessment. They have been included in the discussion on mitigation and monitoring measures (Sections 15.8.1.3 and 15.8.2.3).

The remaining occupied specific residential receptors considered in the health, safety and security assessment are:

- Receptor 1: A group of residential dwellings situated in the southern extremity of the nearby town of Varvarovka, approximately 800 m north of the microtunnel entry points;
- Receptor 2: A group of dwellings on the coast, which include the Shingari holiday complex and the Don holiday complex, approximately 1.3 km south of the microtunnel entry points;
- Receptor 4: A residential dwelling situated in the north-eastern part of Varvarovka, approximately 1.5 km north of the landfall facilities, and 50 m to the north of the Varvarovka bypass road. The dwelling is representative of properties that may be impacted by construction traffic;
- Receptor 8: Two log cabins that have recently been built on cleared land, approximately 1.1 km south of the landfall facilities. These have been considered in the noise assessment;
• Receptor 13: Varvarovka village cemetery located to the northwest of the pipeline corridor at a closest approach of approximately 530 m. The temporary microtunnel access road will run near the cemetery at a distance of 100 m to the east; and

• Receptor 16: Residential properties within Rassvet, which are representative of the properties closest to the proposed construction route and which may be impacted by construction traffic.

15.7.4 Impact Magnitude

Project activities can have impacts on the health of receptor groups.

In the case of community health, it is assumed that a wide range of illnesses and disabilities are already present in the population and this is the baseline prevalence rate. There is a risk that the Project causes, or is attributed to cause, an increase in the incidence and hence prevalence rate of some of the existing conditions. As people value their health, even a small increase in the prevalence rate of a disease or disability that is attributable to the Project is classed as a high magnitude event.

Table 15.9 classifies impact magnitude for the community health, safety and security assessment.

15.7.5 Impact Significance Criteria

In accordance with the methodology adopted for this impact assessment, receptor sensitivity and impact magnitude are combined to assess significance using the matrix shown in Table 15.10. There is no global consensus on the criteria that should be defined and used in community health impact assessments and Good International Industry Practice consists of seeking consistency and transparency. In some cases, professional judgement of significance
has to be made without strict adherence to the magnitude and sensitivity criteria, because the criteria do not apply or need to be adjusted to the health issue under consideration.

Table 15.10 shows a significance assessment matrix regarding the relationship between Receptor Sensitivity and the Event Magnitude of Project impact on the receptors in terms of area and time of impact.

### 15.7.6 Impact Mitigation

The ESIA Report uses the impact mitigation hierarchy (**Chapter 3 Impact Assessment Methodology**). The terminology includes avoid, abate, attenuate, remedy and compensate. These terms may not have obvious meanings in a health context. Table 15.11 provides additional clarification and alternative terminology for community health, safety and security. When advocating mitigation, the highest possible level in the hierarchy should be chosen. For example, there should generally be no obligation for the community to change their own behaviour as a result of the Project in order to remain safe and healthy.

*Continued...*
In the Section 15.8, impacts are assessed and discussed. Mitigation measures are identified to address these impacts following the application of which, the significance of any residual impact (i.e. impact remaining after mitigation measures have been implemented) is stated.

South Stream Transport has developed a Grievance Procedure for the Project, which will guide the management of grievances throughout the Project lifecycle (Chapter 6 Stakeholder Engagement). The Grievance Mechanism will be implemented by South Stream Transport in partnership with its contractors and will ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way. The Grievance Procedure describes the process by which a grievance is documented, investigated, and resolved in coordination with the affected stakeholders.

Monitoring measures and the Grievance Procedure have not been listed individually against impacts in the following sections but can be assumed to apply to all potential Project health, safety and security impacts per the HSSE-IMS (Chapter 22 Environmental and Social Management).

15.8 Assessment of Potential Impact: Community Health, Safety and Security

The assessment takes as its starting point the ‘residual’ impacts and mitigation measures already included in other ESIA chapters. This allows the community health, safety and security assessment to focus on any outstanding issues that have a bearing on community and population health, safety and security and avoids duplication and restatement.

The assessment assumes the successful implementation of mitigation measures described in other ESIA chapters. The mitigations proposed in other ESIA chapters are therefore important to minimising potential impacts and a range of potential impacts have been scoped out on the basis that those mitigations adequately address any potential impact to community health, safety and security. A summary of these potential impacts and the chapters of this ESIA Report where they are discussed is presented in Table 15.12. A fuller explanation of these potential impacts, how they relate to community health, safety and security, along with mitigation measures proposed in the relevant chapters of this ESIA Report and the basis on which these potential impacts have been scoped out of the following assessment is presented in Appendix 15.2.

Collision with other vessels during nearshore and offshore activities resulting in personal injury or fatalities. Fuel and oil leaks and spills from vessels / plant engaged in nearshore and offshore activities.  
Relevant ESIA Chapter: Chapter 19 Unplanned Events

It is important to note that the mitigation measures presented in the community health, safety and security assessment in the remaining sections below are in addition to, and not alternatives to, the measures presented in other chapters and all measures work together in order to achieve the impact rankings presented for residual impacts.

### 15.8.1 Impact Assessment: Construction and Pre-Commissioning Phase

#### 15.8.1.1 Introduction

This section identifies the potential impacts and risks to community health receptors which require further assessment using the community health, safety and security impact assessment methodology. For those effects where potentially significant pre-mitigation impacts are assessed in Section 15.8.1.2, potential mitigation measures have been identified in Section 15.8.1.3. This is followed by a residual impact assessment, the results of which are set out in Section 15.8.1.4.
15.8.1.2 **Assessment of Potential Impacts (Pre-mitigation)**

**Social Factors**

There will be an incoming, temporary workforce required for Project construction (it is not yet known what proportion of this workforce will originate from within the EU). The majority of onshore and offshore workers are likely to be adult males.

The Construction Phase will generate approximately 330 temporary jobs onshore during the peak of construction. It is anticipated that the onshore construction workforce will be accommodated in the local area and that they will interact with local communities. The extent of this interaction will depend on the living, working and recreational conditions for the workforce. Some may originate from the local area having taken up employment opportunities from the Project and so will reside in their own homes.

Offshore construction activities are expected to create 1,185 temporary jobs during the peak of construction. The offshore workforce is anticipated to be specialised teams brought in by the construction contractor and is unlikely to be recruited locally. The offshore workforce will live aboard the vessels on which they work.

The following social factors with community, economic and financial outcomes were identified as potentially giving rise to community and population level health, safety and security impacts:

- Conduct of workforce in the community;
- Spread of sexually transmitted infections; and
- Employment opportunities for the local population.

Each of these is discussed in turn in the sections below.

**Conduct of workforce in the community**

This issue is relevant to the landfall, nearshore and offshore sections of the Project.

Potential for conflict between the local community and the workforce depends on the living, working and recreational conditions for the workforce. For the purposes of this assessment, it has been assumed that the onshore construction workforce will be housed in their own homes (if local to the area) or in the town of Anapa. In this situation, interactions with the local community are likely to be normalized and they are likely to be regarded as community members. Risks of antisocial behaviour and injury are reduced if normal codes of conduct are followed. During the tourist season the workforce is small compared to the number of tourist visitors. Outside the tourist season the numbers of the workforce may be more apparent.

The baseline suggests that alcohol use may be a problem in the region accounting for 10% of the mortality. In general, excessive alcohol use is associated with increased crime, including assault and criminal damage. However, the baseline further indicates that there are generally no incidences of serious disorder in Anapa Resort Town area, even during the summer tourist season (Section 15.5.2.8).
Although it is not yet known if the offshore workforce will interact with the community during transit, the potential for community impacts relating to the offshore workforce is greatest during periods of leave, such as shift changes, when vessel crews can come ashore for short periods of time.

There is also the potential for conflict between communities and direct or contracted workers who will provide security to safeguard the Project’s personnel and property.

The existing mitigation measures to be implemented by the Project include:

- The intention of South Stream Transport is to require its contractors where practicable to provide the opportunity for local people to seek employment opportunities on the Project, which will assist in mitigating the potential for tensions related to unmet employment opportunities.
- To mitigate further these risks, South Stream Transport will keep communities informed about Project activities through on-going stakeholder engagement, and implement the grievance procedure to communicate and resolve any grievances arising from Project activities (see Chapter 6 Stakeholder Engagement for further information).

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be moderate. If the workforce is housed in smaller communities then it would be harder for the host community to limit proximity to the workforce or to avoid particular venues that are visited by the workforce. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be moderate. This is because any altercation, however unlikely, has the potential for serious injury. Applying the scoring of the Significance Matrix the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is Moderate.

**Spread of sexually transmitted infections (STIs) due to in-migration of non-local workers**

This issue is relevant to the landfall, nearshore and offshore sections of the Project.

It is noted that the size of the workforce will be small relative to the large numbers of tourist visitors that ART municipal district receives each year. However, as the majority of workers are expected to be adult males, and as there is scope for a diverse range of countries of origin (particularly for vessel crews), this poses potential risks in terms of transmission of infectious disease. The only specific risk that has been identified is the potential for an increase in the local incidence of sexually transmitted infections (STIs). The sexual activity of the Project workforce during leave and outside of work hours has potential to introduce or spread infectious diseases, including sexually transmitted infections (STIs). The likelihood of this occurring depends on the living, working and recreational conditions for the workforce.

It is noted in the baseline that in 2011, Krasnodar Krai achieved a reduction in newly diagnosed cases of syphilis (Ref. 15.9). These positive results are attributed, in part, to target health promotion and diseases prevention programmes, including “Stop Infections” and National Priority Project “Health”, which are being implemented throughout the region (Ref. 15.10). However, sexual transmission of HIV continues to increase in both the Russian Federation and in the Krasnodar Krai and Injected drug use and heterosexual intercourse are two of the lead
causes of the transmission of the infection (Section 15.5.2.2). There is a stable trend in the incidence of gonorrhoea in ART municipal district.

Commercial sex workers (CSW) can be vulnerable to STIs and can also contribute to the transmission of such infections. The number of CSWs in the Project area is unknown; information from local authorities has indicated that prostitution is not an issue in this family-focused resort area (Ref. 15.5) but the presence of CSWs would not be unexpected, particularly in communities spanning or close to major roads, tourist centres or port towns. People who are deprived, addicted to drugs and/or suffer from mental illness are particularly susceptible to sexual exploitation. The high prevalence of HIV among the drug users population makes this group vulnerable to further spread of the disease and increases the risk of sexual transmission to the general population through commercial sex workers.

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be moderate. This is because of the potential presence of commercial sex workers (particularly around major haul roads and the town of Anapa) who could become infected themselves, and also spread infections. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be high. This is because the infection impacts may go beyond the Construction and Pre-commissioning Phase with wider prevalence implications for local communities and health resources. Applying the scoring of the Significance Matrix the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is **High**.

*Employment opportunities for the local population*

This issue is relevant to the landfall section.

Due to the highly specialised nature of sub-sea pipeline construction, the marine pipe-laying contractor will provide their own workforce and few, if any, local people will be employed for this work. Given this, the potential for the contractor to employ local labour to fulfil unskilled and semi-skilled jobs is largely related to the construction activities for the landfall section of the Project. **Chapter 14 Socio-economics** estimates that construction accounts for approximately 9% to 10% of the local economy, suggesting that there is likely to be a pool of people interested in taking up construction employment opportunities. There is also potential for indirect employment in other sectors.

Employment is associated with positive physical and mental health outcomes: the quality of the employment is associated with the health effect (Ref. 15.30), for example the terms and conditions of the contract and the working conditions. Appropriate training has also been found important (Ref. 15.31). Unemployment is associated with increased mortality rates (Ref. 15.32) (Ref. 15.33).

During consultation undertaken as part of the scoping process, creation of local employment was perceived as an anticipated positive benefit of the Project for local communities (Ref. 15.34). This will include sub-contractors and secondary industries providing goods and services. Population groups likely to disproportionately benefit from job opportunities created by construction activities include the unemployed and people with high levels of deprivation, particularly those on low incomes.
The existing enhancement measures in the ESIA Report include:

- South Stream Transport will encourage the use of local labour for the Project including by requiring its contractors to advertise suitable available positions in local and regional media, use local recruitment agencies and engage in other similar activities, so as to provide the opportunity for local people to access employment opportunities created by the Project; and

- South Stream Transport will require its contractors to advertise suitable available contracts in local and regional media, establish contacts with the local Chamber of Commerce and business associations and engage in other similar activities, so as to provide the opportunity for local suppliers and contractors to seek sub-contractor roles and/or supply materials and equipment to the Project.

Whilst the Project will provide opportunities for local labour to access employment and for local firms to secure contracts for the supply of goods and services; the effects of direct employment are expected to be relatively modest as the majority of the construction workforce required will be highly skilled and is anticipated to come from outside the local area.

For those individual workers that do benefit from employment and service provision opportunities, the impact on the general health of workers and their families is likely to be beneficial, as wealth and status are important social determinants of health.

Positive impacts are not scored using the significance matrix; however, the following points are noted. The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be high. This reflects the potential for the employment benefits to include vulnerable groups, e.g., families with low incomes. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be beneficial and limited.

**Environmental factors**

The following environmental factors that affect the physical environment were identified as potentially giving rise to community and population level health, safety and security impacts:

- Construction noise impacts from vehicles, plant and vessels;
- Impacts on road safety due to construction traffic; and
- Mobilisation of historic seabed pollutants.

Each of these is discussed in turn in the sections below.

*Construction noise impacts from vehicles, plant and vessels*

This issue is relevant to the landfall and nearshore sections.

The ESIA assessment of noise and vibration impacts arising during the Construction and Pre-Commissioning Phase in the nearshore and landfall sections has been combined into a single modelling scenario. As such the nearshore and onshore impact are assessed as a single impact to onshore community receptors.
Noise and vibration emissions from construction plant and vehicles, including: piling; excavation; tunnelling; HGVs; loading; and unloading activities; and construction road traffic have the potential to adversely affect health by disturbance to residential dwellings, local workforce (notably shift workers) and visitors.

A source of night-time noise impacts is the microtunneling operation. This will be undertaken on a 24-hour per day, seven day per week basis and the average rate of tunnel excavation will be approximately 10 m to 15 m per day. It is anticipated that each microtunnel will take approximately four months to excavate.

Excessive or persistent noise exposure can have a detrimental effect on health including on cardiovascular disease and on sleep, work or leisure activities. The baseline notes that circulatory illnesses are the second highest class of adult illness in ART municipal district (Ref. 15.9). High noise levels could potentially exacerbate this situation. During consultation, stakeholders raised concerns about noise and vibration that might adversely affect communities, particularly during the Construction and Pre-Commissioning Phase of the Project (Ref. 15.34).

The existing mitigation measures to be implemented by the Project include (see Chapter 10 Noise and Vibration):

- Equipment will be throttled to a minimum or switched off when not in use;
- Internal access roads will be kept well-maintained to prevent noise impacts generated by vehicles dealing with difficult terrain;
- Drop heights of materials will be minimised which will reduce the noise levels generated by the collision of materials with the ground or other materials;
- As far as reasonably practicable, sources of significant noise will be enclosed;
- Plant and equipment will be used and maintained regularly in accordance with manufacturers’ instructions;
- Where possible, equipment will be located away from noise-sensitive areas. Also, loading and unloading will be carried out away from such areas;
- In consideration of the potential impacts arising from several noisy activities occurring at the same time, activities will be scheduled, where possible, to minimise overall noise levels;
- In order to reduce these noise levels generated by the compressor booster (see below), it is expected that a combination of measures will need to be employed. These include the selection of inherently quiet plant with far lower sound power levels than used in the assessment; careful siting and orientation of the plant to minimise noise emissions at receptor locations; and the use of acoustic berms or barriers close to the pre-commissioning compound; and
- An acoustic screen along the boundary of the properties and Varvarovka bypass road will be installed to mitigate the noise impact. Typically this can be constructed from a timber fence, wall or earth bund, or any combination of the two. For fencing, example design principles to ensure effective mitigation include two layers of staggered boards, giving a minimum superficial mass of 10 kg/m², and ensuring that no air gaps exist at the base of the
structure. The specification will be determined based on the number of vehicle movements on the road along with consultation with the owners of adjacent properties.

The noise assessment undertaken for the Project (Chapter 10 Noise and Vibration) assesses noise impacts for a range of noise scenarios. The residual impact significance of both noise and ground borne vibration at sensitive receptors during the Construction and Pre-Commissioning Phases is predicted to be Not Significant with the exception of two scenarios:

- During periods of the highest traffic flows there is predicted to be an impact of Low impact significance at Receptor 4, the residential dwellings in the north-eastern part of Varvarovka adjacent to the Varvarovka bypass road, following the inclusion of a noise barrier to mitigate noise levels; and

- The activities associated with the use of the compressor booster spread for the cleaning, gauging and drying of the pipelines between the Russian and Bulgarian landfall facilities during Pre-Commissioning, will result in a Low impact significance at a number of neighbouring receptors. It is noted in Chapter 10 Noise and Vibration that the degree of mitigation feasible for this impact cannot be directly quantified at this point in time.

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be moderate. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be low. This is due to the fact that, for the traffic noise impacts, these will occur only during the periods of greatest vehicle movements. For the noise impacts generated by the compressor booster, these will be of short term and temporary duration (less than 4 months). Applying the scoring of the Significance Matrix the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is Low.

Impacts on road safety due to construction traffic, particularly heavy goods vehicles

This issue is relevant to the landfall section.

Potential health impacts arise from the increase in traffic flows and increase of heavy and oversize vehicles on local roads due to construction.

Increases in construction road traffic (movement of materials and personnel) through community areas can result in a number of effects for other road users, such as:

- Reduction in real or perceived road safety;
- Overload of junction capacity;
- Driver delay;
- Community severance;
- Intimidation and fear;
- Reduction in pedestrian amenity; and
- Increase in hazardous loads.
If access routes are poorly conceived, difficult to access, poorly maintained or perceived as unsafe, construction traffic can act as barriers to encouraging the use of active transport modes such as walking and cycling (Ref. 15.37). The density of motorised transport can also negatively affect social cohesion within a community either through direct community severance due to road construction or through the impact of high levels of traffic (Ref. 15.37). As discussed in the baseline, compared with other countries bordering the Black Sea there is a high percentage of pedestrian deaths in the Russian Federation and 72% of deaths occur in urban areas indicating that road traffic and road safety are important considerations for Local Communities. Furthermore, increased risk of road traffic collisions from high traffic density can contribute towards the development of long-term mental health problems in drivers, passengers and victims (Ref. 15.37).

For road safety issues children, the elderly, pedestrians and cyclists are considered to be vulnerable population groups.

During consultation in 2012, stakeholders raised the issue of increased traffic, the impact this could have on Local Communities, and asked whether additional roads would be constructed for the Project (Ref. 15.34). In early 2014, interviews with the local administration for the community of Rassvet, and the local schoolteacher, indicated that increased traffic is an issue in Rassvet, particularly in relation to the children attending the local school and in summer when there is more tourist traffic in the area (Ref. 15.49).

The total construction traffic proposed for the Project comprises a maximum of 531 HGV and 27 light vehicle movements per day; this peak will last from August to November 2014. During June and July 2014, there will be 498 HGV and 14 light vehicle movements per day. The existing mitigation measures and design control measures to reduce traffic impacts presented elsewhere in this ESIA Report include:

- Preparation and implementation of a Traffic Management component of the Russian Landfall CMP to manage and coordinate the transport and logistics requirements of the Project. The Logistics Plan will identify agreed access routes, as well as measures and safeguards to minimise interference with local transportation and routes; and
- Two temporary bypass roads will prevent construction traffic from passing through Local Communities. The first bypass road has been constructed by Gazprom Invest as part of the Expansion of the United Gas Supply System. This road bypasses the town of Gai Kodzor and will be used by Project construction traffic as agreed with Gazprom Invest. The second temporary bypass will be constructed for the Project to bypass the town of Varvarovka when accessing the landfall section during construction of the Project.

Appendix 9.1 concludes that with the provision of the two construction traffic bypasses, the highway network is capable of accommodating the additional traffic without there being any perceptible impact on other road users. Based on this, the majority of transport impacts do not require further assessment from a health, safety and security perspective.

However, the Study notes that the exception is the route through Rassvet, a community on the junction of the M25 where the construction traffic arriving from east and west on the M25 will turn south towards the landfall section of the Project.
During the period when construction traffic is at its highest, the increase in the traffic flow on the road through Rassvet immediately south of the junction with the M25 (Point A on Figure A9.1.2) could be approximately 23% with the increase in terms of heavy vehicles being 154%. To the south of Rassvet and north of the start of the temporary bypass to Gai Kodzor (Point B on Figure A9.1.2) the increase in the number of heavy vehicles could approach 200% because of the lower flow of existing traffic. For the majority of the construction period the increases will be much lower over the section of road between these two points, with the increase in total traffic being around 2% and the increase in heavy vehicles between 11% and 13%.

The HGV traffic through Rassvet will be in addition to that of the HGVs associated with the construction of the Russkaya compressor station (CS) so the actual increase will depend on the level of construction traffic being generated at that time by the Russkaya CS construction (see Appendix 20.1 for further consideration of the cumulative traffic effects expected in conjunction with the construction of the Russkaya CS).

Increased vehicular traffic leads to increased likelihood of road traffic incidents and injuries. There is a direct link between number of kilometres driven and the number of incidents, injuries and fatalities caused. The baseline statistics indicate that alcohol consumption, poor road conditions, and bad traffic management contribute most in Russia to road traffic injuries and deaths. The use of cell phones and texting devices while driving is another growing risk factor. Due to the proximity to residential, commercial and community properties lining the road in Rassvet (see Section 15.5.2.7), the number of pedestrians or cyclists encountered by construction traffic is expected to be higher in the community of Rassvet compared to on the M25. Figure 15.14 shows the side of the road through Rassvet being used by cyclists, demonstrating their potential vulnerability to high volumes of HGVs.

**Figure 15.14 M25 Pedestrian Crossing just West of Rassvet Turning (Ref. 15.40)**

For road safety, the sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be high. This is due to certain vulnerable sub-populations (e.g. children and the elderly) being present among the general population of road users, including pedestrians, motorists and vehicle passengers. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be high. This is because
although temporary, there is a period of intense activity lasting six months during construction when large numbers of HGV and other vehicle movements will occur. Applying the scoring of the Significance Matrix the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is **High**.

**Mobilisation of historic seabed pollutants during trenching and tunnelling**

This issue is relevant to the nearshore section.

There is potential for nearshore dredging and pipe-laying activities to disturb and mobilise existing toxins or pollutants (including chemicals from unexploded munitions (UXO)) within the seabed. Toxins from these activities have the potential to enter the human food chain either directly if consumed whilst engaging in marine leisure activities; or if consumed following assimilation (and potentially accumulation) in fish, mollusc or crustacean intermediates. Children and young people’s developmental processes are particularly sensitive to exposure to contaminants. As well as the potential illness, there could also be economic loss for businesses reliant on coastal waters. People with high levels of deprivation, particularly those on low incomes would be more sensitive to loss of income due to reduced tourism or commercial marine activity.

ART municipal district has been given the status of a health resort town since 1957 and is a specially protected natural area (SPNA) of the federal level. The SPNA is categorized as “health improving (spa) resort area”. Linked to this status there are recreational uses of the beach at Sukko, Shingari and Don holiday complexes and other nearby waters, including swimming, fishing, paragliding, jet skiing and diving. During consultation stakeholders raised the issue of potential environmental damage that may affect fishing and recreation (Ref. 15.34).

An indication of the likely extent of sediment plumes due to seabed disturbance is provided by Sediment Dispersion Modelling (Ref. 15.41). The model shows that a plume will persist throughout the construction dredging activities, gradually dissipating following their completion. The sediment plume travels in the direction of the current along the Russian coastline. The modelling shows the extent of sediment plumes associated with different underwater seabed disturbance activities and how the effect varies with depth and direction of current. For the purposes of this discussion the only activity that is likely to result in an impact to bathing waters is pre-lay dredging at the pipeline exit points from the microtunnel. Under this scenario there is the potential for the sediment plume to affect beaches and bathing waters over a long stretch of coastline to the south, particularly the first 5.5 km including Sukko beach. The greatest effect occurs when seabed disturbance is undertaken during clockwise currents (Scenario 1 of that report).

Figure 15.15 is an illustrative example from the technical report (Ref. 15.41) showing the point with the greatest potential impact on bathing waters during a clockwise current. At the exit points, the proposed dredging and disposal operation lasts for 1.3 days for one pipeline operation. The sediment plume dissipates within 120 hours or approximately 5 days. The situation is considerably improved if seabed disturbance occurs under counter-clockwise current conditions. When this scenario is modelled the sediment plume is greatly reduced and extends to the north away from popular bathing waters. Under these conditions (Scenario 2 of that report) the plume disperses within 60 hours or less than three days. Figure 15.16 is an
illustrative example from the technical report (Ref. 15.41) showing the greatly reduced potential impact on bathing waters during a counter-clockwise current.

The modelling suggests that the impact on bathing waters, if any contaminants are mobilized and transported with the plume, would be greatly reduced if dredging at the microtunnel exit points was undertaken under counter-clockwise current conditions. The presence of inert sediment in the water is not anticipated to result in any direct health impacts, but could cause anxiety and reductions in leisure activities including those undertaken by guests of the local tourism businesses.

Figure 15.15 Clockwise Current Sediment Plume Extending South to Sukko Beach (Ref. 15.41)
The ESIA reports that previous surveys in the area have identified the presence of contaminants in the marine sediments. Contaminants previously identified include petroleum hydrocarbons, phenols, anionic surfactants and heavy metals. Concentrations were typically highest near the coast, particularly in the vicinity of the main towns (Chapter 7 Physical and Geophysical Environment). Previous surveys in the Russian Sector of the Black Sea have also identified the presence of contaminants in the sea water itself, including several organochlorine pesticides, petroleum hydrocarbons, phenols, and anionic surfactants. Additionally, elevated concentrations of heavy metals were locally detected, including copper, cadmium, lead, mercury and zinc. Contaminant concentrations varied spatially, but were typically higher near the coast.

As part of surveys for this Project, bacteriological testing was undertaken on two coastal samples collected in summer 2011. The results are consistent with relatively low levels of faecal contamination. Based on the limited testing, the waters meet the microbiological requirements of SanPiN 2.1.5.2582-10 (Chapter 7 Physical and Geophysical Environment). Marine water quality surveys were also undertaken in autumn 2010 and spring 2011; and marine sediment sampling from the seabed was undertaken between 2010 and 2011 and in July 2013. The 2013 survey included coring within the area to be dredged and areas of seabed intervention to establish levels of potential contamination within the sediment in these. The sediment samples were visually described before undergoing chemical analysis and grain size distribution analysis.

The existing mitigation measures in the ESIA Report include:

- Undertake UXO survey. If required, a UXO specialist will provide watching brief during excavation;
Dredged spoil in the nearshore zone (i.e. from microtunnelling activities) will be temporarily stored in designated offshore storage areas. This material will be subsequently re-dredged and used for trench backfill following pipe installation;

Offshore dredged material will be disposed of at an existing underwater disposal site (no. 923, located on the Russian continental slope);

In the event that any dredge spoil is identified as contaminated or requires disposal on land, the spoil will be treated as construction waste and appropriately stored, transported and disposed of;

Implement a Dredging Management Plan to ensure careful spoil handling and minimise release of material to the water column;

Where dredging is required, the choice of dredger will be made to minimise sediment re-suspension (within engineering constraints). Additional turbidity reduction measures such as silt curtains if feasible, particularly where sediment is to be temporarily re-deposited in nearshore storage areas;

Spill kits shall be kept in accessible locations at all times during the Construction and Pre-Commissioning, Operational and Decommissioning Phases, and employees will be trained in their use and disposal;

Avoid use of additives containing hazardous chemicals in slurry as far as is practicable; and

After completion of the microtunnel works, any remaining slurry will be transported from the used slurry storage tank to a licensed waste facility approved local waste water treatment plants, where it is typically handled as normal soil waste. By undertaking careful calculations of slurry requirements and using efficient slurry recycling systems, the amount of surplus slurry will be kept to a minimum.

The results of the marine water and sediment surveys showed that in the Shallow Water Coastal Area phenol concentrations in excess of Adopted Marine Sediment Standard (AMSS) were identified in 14 of the 15 marine sediment samples. One of six marine core samples also exceeded AMSS for petroleum products. Chapter 7 Physical and Geophysical Environment presents information on levels of contamination, but does not conclude on potential impacts. Based on these findings, the only potential concerns to community and population health are from phenol and petroleum product contaminants in marine sediment and these are considered in the following sections.

Phenol

Acute effects of phenol exposure are only expected from contact or ingestion (or inhalation) of concentrated quantities of phenol. Such exposure would only be expected in an occupational setting and is not discussed further in this section.

Non-occupational exposure to phenol may occur by drinking contaminated water. The threshold for exposure via ingestion is 1 to 32g. Phenol in marine sediments samples for 2010 to 2011 in Shallow Water Coastal Areas occurred in the range of 0.05 to 0.40 mg/kg. Phenol in sea water samples for 2010 to 2011 occurred in the range of <0.1 to 6.1 µg/L. As phenol readily dissolves in water, the dilution effect makes it very unlikely that disturbance of recorded concentrations of phenol in the seabed and seawater will affect bathing water quality to the extent required to
produce a detectable human health effect. It is very unlikely therefore that the general population will be exposed to a level of phenol high enough to cause adverse health effects (Ref. 15.42).

**Petroleum Products**

Total petroleum hydrocarbons (TPH) is a term used to describe a large family of several hundred chemical compounds that originally come from crude oil. Crude oil is used to make petroleum products, which can contaminate the environment. Because there are so many different chemicals in crude oil and in other petroleum products, it is not practical to measure each one separately. The collective term of TPH is therefore applied.

The extent of absorption of TPH by dermal routes varies because of the wide range of physical and chemical properties observed for these chemicals. The extent of absorption depends on the volatility, solubility, lipophilicity, and other properties of the specific chemical or mixture. (Ref. 15.43).

It would generally be expected that dermal exposure (e.g. skin contact when swimming) would produce less severe symptoms or toxicity than ingestion. As the contamination would be in seawater, ingestion in any significant quantity can be ruled out. Where petroleum products are dissolved or in suspension within the seawater the potential for high exposure concentrations is considerably reduced by dilution. However where Project activities disturb concentrations of seabed petroleum products, TPHs may congregate as a film on the water's surface, resulting in higher exposure doses to recreational marine users.

Due to the diversity of potential chemical components it is not practical to consider particular exposure concentration thresholds. However the concentrations detected by marine sediment samples do not give rise to obvious concerns, with the highest detected concentration being 407 mg/kg.

**Overall historic seabed pollutant impact**

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be high. This reflects a precautionary approach since certain vulnerable sub-populations may occur e.g. children during some periods when sediment disturbing activities are occurring. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be low. Although the sample concentration levels indicate a low level that could be considered to be negligible, there is the potential for more extensive or concentrated contamination to be encountered (e.g. petroleum products) which could either concentrate at the surface or be transported in sediment plumes. Applying the scoring of the Significance Matrix and professional judgement, the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is Low/Moderate.

**Institutional factors**

The quality and quantity of local health and emergency service resources is an institutional factor identified as potentially giving rise to community and population level health, safety and security impacts.
Local health and emergency service resources due to in-migration of non-local workers

This issue is relevant to the landfall section.

The Construction and Pre-Commissioning Phase may impact on local health and emergency response service providers, as the Project may affect demand for their resources, particularly in the event of an unplanned event that affects large numbers of the construction workforce.

Lack of availability and accessibility of municipal services such as libraries, health facilities, doctors’ surgeries, schools and social support can have a negative social impact on communities and affect both physical and mental health (Ref. 15.37).

The baseline notes that in the ranking applied by a State Report on Sanitary Epidemiological and Consumer Protection in the Krasnodar region, ART municipal district is placed in the mid-range for healthcare expenditure and in the highest range for per capita physician coverage.

Chapter 5 Project Description states that first aid and medical emergency response will be available to workers as part of the Occupational Health and Safety procedures (see also Appendix 15.1). However, no on-site medical facilities will be provided. Furthermore the facilities, personnel and resources that will be needed to support the provision of medical services for workers will be provided at local hospitals and clinics. The increase in population (assuming a temporary construction phase landfall section workforce of 330 workers at peak) would equate to a temporary increase in the permanent population of the Anapa Resort Town municipal district of approximately 0.14%.

As discussed in Section 15.4.3, interviews with ART municipal district Administration (including the Deputy Chief for Health) in early 2013 and early 2014 confirmed that there is no perceived shortage of facilities or health professionals; during the peak season the authorities bring in extra medical staff and transport (ambulances); and free medical services are provided to Russian citizens whether or not they are based in the ART municipal district (Ref. 15.13).

On this basis, coupled with data on health infrastructure (Section 15.5.3.4 and Tables 15.5 and 15.6), no existing shortages of local health facility provision were identified and therefore it was concluded that the number of non-local workers likely to lodge within Local Communities is not expected to be high enough to have any significant impact on the demand for local health facilities.

Nevertheless, there is a need for further investigation, prior to construction activities commencing, of health conditions and facilities as part of the assessment of workforce accommodation options. This will ensure that the health needs of the workforce (onshore and offshore) are met in a way that does not adversely affect health services for the town of Anapa and the Local Communities.

No specific mitigation measures to manage potential periods of high demand on local health and emergency service resources have been identified as being included from other ESIA chapters or assessments. However, other existing related mitigation measures in the ESIA Report include:

- The site-specific Emergency Response Plans that will be prepared and maintained by each construction contractor will include measures that aim to protect the workforce and
members of the public. These plans will define measures that aim to initially stabilize medical cases (which would be carried out by an on-site first aider, nurse or physician) and then enable evacuation carried out by ambulance or helicopter. The injured party would be evacuated to the nearest designated hospital or accident and emergency centre;

- Each contractor will ensure that sufficient first-aid or medical staff and equipment are located at the construction site to meet the identified occupational health risks; and
- The location and capability of local ambulance stations (public and private) will be identified (and mapped) together with contact details, times of operation, distance and travel times. A qualified occupational physician will inspect and report on the capacity and capability of these services. A designated hospital or accident and emergency centre will also be identified (including contact details, times of operation, distance and expected travel times).

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be high as it concerns people seeking medical care. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be low. This is because the resource demands of the construction workforce are expected to be small in the context of the local population, particularly when seasonal tourism is considered. Applying the scoring of the Significance Matrix and professional judgement, the significance of health impacts arising from this issue, without including any additional mitigation or monitoring requirements, is Low/Moderate.

15.8.1.3 Mitigation and Enhancement

The mitigation measures recommended in relation to each of the significant adverse impacts are set out below. Enhancement measures, which have the potential to enhance beneficial outcomes of the Project, are also outlined.

A Community Health Construction Management Plan will form part of the Environmental and Social Management Plans for the Project. The CHCMP will establish the proposed actions needed to mitigate identified impacts and promote health opportunities in the Project. The CHCMP will assign actions, timeframes, resources, responsibilities and collaborating organizations to the mitigation and enhancement measures identified in this assessment. It will include a monitoring system designed to track implementation progress and selected outcomes. The monitoring system will include appropriate key performance indicators and an early-warning system for any problems occurring at the community level. Evaluation and Verification protocols will also be included to determine when successful implementation has been accomplished. The CHCMP will be reviewed by key stakeholders prior to construction activities commencing. It will incorporate key findings from the Rapid Health Appraisal which will provide additional baseline data and set further parameters for mitigation during the Construction Phase.
Social factors

Conduct of the workforce in the community

- All workers contracted or sub-contracted for this Project will be required to comply with a code of conduct to the extent that contractual requirements governing periods of leave and out of work hours allow;
- South Stream Transport will be guided by applicable law, the principles of proportionality and Good International Industry Practice in relation to hiring, rules of conduct, training, equipping, and monitoring of security forces;
- Residents and visitors to the town of Anapa and the Local Communities will be able to contact the Project at any time and utilize the Grievance Procedure if there are any concerns regarding security arrangements and acts of security personnel;
- As part of the HSSE-IMS, a Security Plan will be developed for each phase of the Project per Good International Industry Practice; and
- If government security personnel are deployed for Project security, South Stream Transport will make every effort to ensure the above training, due diligence, and monitoring are also employed.

Spread of sexually transmitted infections (STIs) due to in-migration of non-local workers

- All workers contracted or sub-contracted for this Project will be required to attend an awareness and educational programme that covers the risks associated with sexually transmitted infections (STIs);
- Specific sexual health testing and clinic facilities will be identified for the Project;
- Condoms will be made available to the workforce; and
- South Stream Transport will have a policy statement regarding sexually transmitted infections (STIs) including HIV/AIDS, and this policy will be communicated internally to staff, and externally to Contractors.

Employment opportunities for the local population

- No further enhancement measures are proposed.

Environmental factors

Construction noise impacts from vehicles, plant and vessels

- In the event that ‘Lesnaya Polyana’ or ‘Club Village Chateau’ (Ref. 15.36) become occupied during the construction of the landfall facilities, South Stream Transport will further assess noise levels in respect of legal requirements and determine appropriate mitigation measures.
Road transport impacts, particularly heavy goods vehicles

General mitigation for traffic safety impacts on the community

Measures will be implemented by South Stream Transport prior to construction works commencing, to address transportation related impacts, including:

- Preparation and implementation of a Traffic Management component of the Russian Landfall CMP. The CMP will:
  - Be consistent with, and take into consideration, the construction traffic management procedures that are followed by Gazprom Invest as part of the construction of the Russkaya CS;
  - Be aligned with the Logistics Plan and ensure that access to the pipeline landfall and associated above ground installations will be restricted to the agreed access routes and the construction corridor;
  - Ensure that movement of ‘outsize’ or ‘large/long’ vehicles, or convoys, will be timed, where practicable, to avoid busy traffic periods and will be restricted to the agreed access routes and the construction corridor; and
  - Include strict enforcement of speed limits for employees driving company vehicles and adherence to driving and health and safety guidelines during both work and non-work hours.

- The implementation of safe driving protocols. These protocols will include the following measures:
  - Drivers will be briefed to maintain vehicular access to all existing properties and relevant safety measures to be applied along the designated construction access route;
  - Training and enforcement to ensure that all South Stream Transport and Contractor drivers adhere to all Russian driving rules;
  - All drivers will be trained in ‘well driven’ principles and guidance; and
  - Driving performance will be assessed and monitored with additional training provided if necessary.

Mitigation specific to the community of Rassvet

South Stream Transport will liaise with local authorities regarding the installation of a pedestrian crossing in Rassvet at an appropriate location for the community. The crossing will be of a standard and quality similar to that shown in Figure 15.12 (pedestrian crossing to a bus shelter on the M25 just west of the turning into Rassvet).

South Stream Transport will undertake further traffic assessment at the community of Rassvet to determine:

- The state of road safety infrastructure including the existence of: pavements, cycle lanes, traffic calming measures and pedestrian crossings;
- The need for any additional mitigation measures such as the installation of further pedestrian crossings and other appropriate traffic calming measures;
• The physical state of the road infrastructure and determine measures to be taken to restore the state of the road between the highway, through Rassvet, to the turn-off to the Gai Kodzor bypass; and

• As part of the Traffic Management component of the Russian Landfall CMP, all drivers contracted or sub-contracted for this Project will be required to attend an awareness and training programme that covers road safety and emphasises the vulnerability of cyclists and compliance with pedestrian road crossings in and around Rassvet.

**Mobilisation of historic seabed pollutants during trenching and tunnelling**

• Protocols similar to those that will be used in the event of marine fuel spills will be prepared and followed to deal with any disturbance of petroleum products in the marine sediment that result in a significant oil film at the surface; and

• The use of bentonite mud for microtunnelling (an inert, heavy and sticky substance which pools on seabed and doesn't disperse) will be carefully planned and monitored to avoid deposits migrating into bathing waters.

**Institutional factors**

**Local health and emergency service resources due to in-migration of non-local workers**

• Prior to construction activities commencing, agreement will be reached with local health services as part of the Rapid Health Appraisal (see below) to confirm how the healthcare needs of the construction workforce, including non-Russian workers, will be met. Such consultation will include a solution that avoids any adverse impact to local populations due to resource demands of the Project being greatest at the nearest healthcare facilities;

• With local health services and other authorities on how demand for health and other emergency response services will be met in the event of an unplanned event that affects both Local Communities and the construction workforce;

• The location of hospitals, clinics, doctors’ surgeries and pharmacies will be identified to ensure that access to and from them is not restricted by Project activities or that alternative access is in place and has been agreed with the local health authorities; and

• The construction contractor will undertake a Rapid Health Appraisal of the potential socio-economic and health impacts related to the preferred option(s) for workforce accommodation during the Construction and Pre-Commissioning Phase of the Project. The purpose of this appraisal is to avoid significant adverse impacts on the town of Anapa and the Local Communities by identifying potential impacts and appropriate mitigation and management measures prior to the start of construction and to confirm appropriate housing and health provision is in place prior to making accommodation arrangements for the onshore workforce. The appraisal may include consultation with applicable local and regional authorities, including health and social service providers and will include an assessment of local health conditions and services. The assessment will also include a review of the accommodation, conduct, sexual health and general health service resource requirements of the estimated offshore workforce, employed to work aboard Project vessels, during periods of shore based transit to and from their vessels.
15.8.1.4 Residual Impacts

This section presents a summary of the potential Construction and Pre-commissioning Phase residual community health and safety impacts arising from the Project following application of the identified mitigation measures.

Social factors

Conduct of workforce in the community

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA, the residual significance of potential community/population health impacts arising from the conduct of the workforce, including the offshore workforce, if any, in the town of Anapa and the Local Communities during the Construction and Pre-Commissioning Phase is considered to be Low.

Spread of sexually transmitted infections (STIs) due to in-migration of non-local workers (STIs)

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; and assuming the Rapid Health Appraisal determines that the assumptions made for sexually transmitted diseases due to lack of baseline data are accurate, the residual significance of potential community and population health impacts arising from the spread of sexually transmitted infections (STIs) during the Construction and Pre-Commissioning Phase is considered to be Low.

Employment opportunities for the local population

Subject to the full adoption of the enhancement measures set out in the ESIA Report; the residual significance of potential community / population health impacts arising from employment opportunities during the Construction and Pre-Commissioning Phase is considered to be limited and beneficial.

Environmental factors

Construction noise impacts from vehicles, plant and vessels

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; the residual significance of potential community and population health impacts arising from construction noise impacts during the Construction and Pre-Commissioning Phase is considered to be Low.

Road transport impacts, particularly heavy goods vehicles

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; the residual significance of potential community and population health impacts arising from road transport impacts during the Construction and Pre-Commissioning Phase is considered to be Low / Moderate.

Mobilisation of historic ground contaminants during site clearance and trenching

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; the residual significance of potential community and population health impacts arising from mobilisation of historic ground contaminants during the Construction and Pre-Commissioning Phase is considered to be Not Significant.

Institutional factors

Local health and emergency service resources due to in-migration of non-local workers

At this point in time, and based on the information collected to date through engagement with local health authorities, the expected Project workforce for construction in the landfall section of the Project will not have a significant impact on health care infrastructure of Anapa Resort Town and will not place undue pressure on existing health facilities. Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; and any additional information obtained during the Rapid Health Appraisal and through continuous engagement with local health authorities, the residual significance of potential community and population health impacts arising to local health and emergency service resources during the Construction and Pre-Commissioning Phase is considered to be Not Significant.

15.8.1.5 Monitoring

South Stream Transport will develop an Environmental and Social Monitoring Plan for the Project which will detail all monitoring requirements applicable to the Project regardless of associated phase, topic or location. Chapter 22 Environmental and Social Management discusses the monitoring programme based on the monitoring requirements across the ESIA Report. This section briefly outlines the key issues, receptors and monitoring activities for community health, safety and security during the Construction and Pre-commissioning Phase of the Project.

Social factors

Conduct of workforce in the community

The monitoring programme will record any issues of poor conduct by the Project’s workforce (including contractors and sub-contractors) in the town of Anapa and the Local Communities, and will cover offshore workforce interaction, if any, with the local population (residents and visitors). Additional mitigation measures will be adopted and consultation will be undertaken with local law enforcement and health and social service providers, especially as it pertains to potential impacts to CSW, as necessary and indicated by monitoring results.

This will include monitoring the number of grievances raised by local residents via the Grievance Procedure relating to the workforce and its interaction with the community, including the number of anti-social incidents involving workforce recorded by police, monitoring of health statistics (e.g. of STDs and HIV / AIDS) recorded by local health officials, and recording of any incidents where the worker code of conduct has been violated and whether this has triggered local health / emergency response.
*Spread of sexually transmitted infections (STIs) due to presence of workers (STIs)*

South Stream Transport will work with local public health and commercial sex worker support organisations to monitor any adverse effects attributable to the Project workforce or Project activities. If significant adverse impacts are indicated then additional mitigation measures will be adopted in collaboration with those organisations.

*Employment opportunities for the local population*

The monitoring programme will record the number of employment opportunities advertised in local media and taken up by members of the Local Communities.

*Environmental factors*

*Construction noise impacts from vehicles, plant and vessels*

Noise impacts to human receptors and monitoring thereof are addressed in Chapter 10 Noise and Vibration. With regard to the construction activities monitoring has been specified to occur at the start of the following activities:

- Daytime construction traffic during period of maximum movements (Mid Jun – Nov 2014);
- Daytime trenching, pipe fabrication, pipe laying and landfall facilities construction; and
- Night-time microtunnelling works.

*Road transport impacts, particularly heavy goods vehicles*

The monitoring programme will record the impact of construction transport on road safety and community severance in Rassvet. Monitoring will include vehicle counts and consultation with residents of Rassvet. If the monitoring indicates that road safety or community severance becomes a significant concern for the local community then further mitigation measures will be investigated.

Monitoring of vehicles based on construction site vehicle entry and exit data will be undertaken and results collated on a regular basis. Perception monitoring in regards to traffic and other potential issues recommended as part of regular stakeholder engagement with communities – including with schools, shop owners, local community leaders. Rassvet and Varvarovka engagement will be held regularly or as otherwise agreed with the relevant municipal / rural district administrations; and with the other communities as warranted or if a grievance is filed.

*Mobilisation of historic seabed pollutants during trenching and tunnelling*

During dredging, backfilling and trenchless tunnelling activities water quality will be monitored to check that national bathing water quality standards are maintained in surrounding coastal areas, particularly at popular beach locations such as Sukko beach and Shingari Holiday Complex. Monitoring will include engagement with the Shingari and Don holiday complexes. If monitoring indicates that bathing water quality is affected by the Project’s activities then further mitigation measures may be required.
Institutional factors

Local health and emergency service resources due to increase of non-local workers

Monitoring of potential changes in the demand and capacity for accommodation, local health and emergency services will be primarily undertaken through direct engagement with local officials, and health and emergency response service providers to discuss whether or not the Project has had increased demands on local health and emergency service resources.

The first such engagement will be undertaken through a face-to-face meeting, and regular engagement will be established (e.g. quarterly or semi-annually) to review the use of health and emergency services related to the Project’s workforce and activities. Carrying out engagement with local officials and service providers will also enable South Stream Transport to identify any trends or qualitative changes. South Stream Transport will also monitor their own records (such as Human Resource data, the Grievance Mechanism) for any workplace incidents that may require a response from local officials, health and emergency providers. Open lines of communication will also be established between South Stream Transport, the Contractor, and local service providers.

If monitoring indicates that service demand as a result of the Project is causing resource shortages further mitigation measures will be investigated to ensure that Local Communities are not adversely affected.

15.8.2 Impact Assessment: Operational Phase

15.8.2.1 Introduction

This section identifies the potential impacts and risks to community health, safety and security receptors during the Operational Phase of the Project. For those effects where potentially significant pre-mitigation impacts are assessed in Section 15.8.2.2, potential mitigation measures have been identified in Section 15.8.2.3, followed by a residual impact assessment, the results of which are set out in Section 15.8.2.4.

15.8.2.2 Assessment of Potential Impacts (Pre-mitigation)

Social factors

The following potential impacts resulting from Project activities with community, economic, and financial outcomes were identified as potentially giving rise to community or population level health impacts.

Public anxiety over large volumes of gas close to Local Communities

This issue is relevant to the landfall section.

Perceptions of fear arising from risks of controlled or uncontrolled natural gas releases may give rise to public anxiety.
Stakeholder comments cited safety as a concern, including a fear of potential gas explosion or fire (Ref. 15.34) and the possibility of seismic activity (Ref. 15.34).

The existing mitigation measures in the ESIA Report include:

- Consultation with stakeholders, including the residents of the town of Anapa and the Local Communities has been on-going and will continue, including for disclosure of the ESMPs, as outlined in Chapter 6 Stakeholder Engagement; and

- South Stream Transport has developed a Stakeholder Engagement Plan which identifies stakeholders and their interests, describes the consultation undertaken and that planned as part of the Project’s ESIA process, and establishes a framework for stakeholder engagement activities to be undertaken as the Project progresses beyond the ESIA phase.

Public anxiety can reasonably be expected to decrease as public understanding develops amongst the local population of the design controls and as the design controls are seen to be effective. For example the air quality assessment notes that the vent stack height has been pre-determined based on safety requirements in the workplace in order to manage air quality and protect workers from the unlikely event that the vented gas might ignite. This level of localised dispersion to safe levels for onsite maintenance personnel, should reassure local residents that there is not expected to be a risk to community receptors, which are far more distant. The continuing success of such alleviation will also depend on good communication between the Project and the local population.

The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be low. Certain vulnerable sub-populations may be concerned about these processes, e.g. people with existing anxiety type disorders. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be moderate. An unknown number of people may experience mental ill health, such as increased anxiety and stress, for more than one month as a result of the proposed works. Applying the scoring of the Significance Matrix the significance of health impacts arising from this activity, without including any additional mitigation or monitoring requirements, is considered to be Low.

**Benefits to the Russian economy from increased gas sales**

This issue is relevant to the landfall, nearshore and offshore sections.

The Project will increase demand for Russian goods and services (gas) and increase government revenues, taxes and royalties. On this basis the socio-economic assessment concludes that there will be a beneficial economic impact nationally from gas sales associated with the Project.

The total current gas pipeline capacity between Russia and Europe is approximately 200 bcm/year, which will increase to 318 bcm/year if the South Stream Pipeline System and other new projects are completed. This could in turn lead to an increase in Russian gas production and sales. In this case, the Project would give rise to increased tax revenues for the Russian government of several billion euros annually. On this basis the socio-economic assessment concludes that there will be a beneficial economic impact nationally from gas sales associated with the Project.
There is the potential for the additional government income generated though gas sales (made possible by this development) to be spent on directly or indirectly improving the health and wellbeing of the Russian people.

The baseline notes that a comparison of socio-economic indicators of well-off and disadvantaged mortality in Krasnodar Krai in 2010 revealed that there is a very high dependency between the levels of investment in the area and the wellbeing of the population. Coverage by physicians, salary, and healthcare expenditures also pay a key role in population wellbeing.

Positive impacts are not scored using the significance matrix; however the following points are noted. The sensitivity of the local population, including consideration of particular vulnerabilities, is considered to be moderate. This reflects the fact that benefits will be diluted across the Russian people. The magnitude of change caused by the Project that has the potential to affect health outcomes is considered to be Beneficial and Limited.

**Environmental factors**

No potential impacts resulting from Project activities that affect the physical environment were identified as potentially giving rise to community or population level health impacts.

**Institutional factors**

No potential impacts resulting from project activities that affect institutional factors were identified as potentially giving rise to community or population level health impacts. See the Unplanned Events section (Section 15.10) for issues relating to institutional involvement in the unlikely event of uncontrolled release of gas from the pipeline.

**15.8.2.3 Mitigation and Enhancement**

The mitigation measures recommended in relation to each of the significant adverse impacts is set out below. Enhancement measures, which have the potential to enhance beneficial outcomes of the Project, are also addressed.

**Social factors**

*Public anxiety over large volumes of gas close to Local Communities*

Stakeholder engagement will be continued throughout the life of the Project to ensure that appropriate Project information on operations and safety is communicated.

*Benefits to the Russian economy from increased gas sales*

This issue is outside the Project’s control.

**15.8.2.4 Residual Impacts**

The below section presents a summary of the potential Construction and Pre-commissioning phase residual community health and wellbeing impacts arising from the Project following application of the identified mitigation measures.
Social factors

Public anxiety over large volumes of gas close to Local Communities

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; the residual significance of potential community and population health impacts arising from Public anxiety during the Operational Phase are considered to be Not Significant.

Benefits to the Russian economy from increased gas sales

Subject to the full adoption of the mitigation measures set out in this chapter and elsewhere in the ESIA Report; the residual significance of potential community and population health impacts arising from benefits to the Russian economy during the Operational Phase are considered to be Beneficial and Limited.

Environmental factors

No potential impacts resulting from Project activities that affect the physical environment were identified as potentially giving rise to community or population level health impacts.

Institutional factors

No potential impacts resulting from Project activities that affect institutional factors were identified as potentially giving rise to community or population level health impacts. See the Unplanned Events section (section 15.10) for issues relating to institutional involvement in the unlikely event of uncontrolled release of gas from the Pipeline.

</table>
15.8.2.5 Monitoring

South Stream Transport will develop an Environmental and Social Monitoring Programme for the Project which will detail all monitoring requirements applicable to the Project regardless of associated phase, topic or location. Chapter 22 Environmental and Social Management discusses the monitoring programme based on the monitoring requirements across the ESIA Report. This section briefly outlines the key issues, receptors and monitoring activities for community health, safety and security during the Operational Phase of the Project.

Social factors

Conduct of workers in the community

The monitoring programme will continue to record any issues of poor conduct by the Project’s workforce (including contractors and sub-contractors) in the town of Anapa and Local Communities. If a grievance is filed by a member of the Local Community or Local Law Enforcement Providers a meeting will be held with the local Law Enforcement Providers in relation to workforce conduct.

Public anxiety over large volumes of gas close to Local Communities

The monitoring programme will include on-going consultation with residents of Local Communities and the local health authorities.

Benefits to the Russian economy from increased gas sales

This issue is outside the Project’s control.

Environmental factors

No monitoring requirement has been identified.

Institutional factors

No monitoring requirement has been identified.

15.8.3 Impact Assessment: Decommissioning

The Project will be decommissioned many years into the future and impacts during the Decommissioning Phase depend on the alternatives chosen at that time – preservation of the pipelines in place or complete or partial removal. If the latter option is chosen and construction activities (e.g. excavation, removal of pipeline, land rehabilitation) are carried out or construction equipment is used, then impacts are expected to be similar to those assessed in

5 The Project Life (i.e. the duration of the Operational Phase) is estimated to be approximately 50 years. As such, decommissioning would take place sometime in the mid to late 2060s.
Section 15.8.1 in relation to the Construction Phase – i.e., generation of employment (beneficial impacts), increased demand for goods and services (beneficial impacts), and impacts on land users (potentially adverse, depending on whether or not productive land uses such as agriculture were disturbed). However, such impacts are likely to be at lower levels and short-term. Assuming that the restriction on areas governing the type and scale of development that can take place on land within certain circumference of the Pipeline are removed, there may be beneficial impacts for land owners associated with the liberalisation of development rights.

A careful record and archive of construction and operation activities will be maintained in a suitable format for future users of such information. It will include any special mitigation measures that were applied retrospectively, in addition to those identified prospectively in this impact assessment. It will also record all unexpected events that occurred during the Construction and Pre-Commissioning and Operational Phases of the Project.

15.9 Occupational Health and Safety

Occupational Health and Safety is discussed in Appendix 15.1.

15.10 Unplanned Events

Unplanned events are discussed in Chapter 19 Unplanned Events, while community perceptions of unplanned events are discussed under the issue of ‘Public Anxiety’ in Section 15.8.2.

15.11 Cumulative Impacts

The cumulative impacts associated with the Project, and those relating to the Russkaya CS, relating to Community Health, Safety and Security are assessed in Chapter 20 Cumulative Impact Assessment.

15.12 Conclusion

This chapter has assessed the potential effects of the Project on Community Health and Safety and set out the Project approach to Community Health and Safety. This assessment has been conducted following the standards and guidelines for financing, as well as national legislation and GIIP.

The Construction Phase of the Project will bring limited direct employment opportunities to Local Communities at the landfall facilities. Procurement of goods and services will also give rise to limited indirect employment across a wider area. This local employment is relatively small in number and while the effects will also be small they will be beneficial.

The infrastructure and logistics requirements of the Project mean that there are inevitably some adverse effects for certain population groups. Large construction sites and busy transport corridors can be disruptive for Local Communities. These may manifest as negative health outcomes. South Stream Transport recognises this risk and will take appropriate measures to reduce disruption through mitigation measures that will govern the movement of transport,
noise from Project vehicles and emissions to air. The Project will also maintain communication with Local Communities to ensure that any grievances are addressed promptly.

The Operational Phase of the Project will bring economic benefits to the Russian Federation, which could translate into greater expenditure on infrastructure and initiatives that directly or indirectly improve health across the nation. The Project will also improve energy supply to gas consumers in the EU.

Overall, although this chapter has identified a number of issues that have the potential to give rise to adverse health impacts, mitigation will be included to reduce the residual impact to an acceptable level for both the community and the workforce.

16 Cultural Heritage

16.1 Introduction

This chapter presents an assessment of the predicted impacts associated with cultural heritage during the Construction and Pre-commissioning, Operational (includes Commissioning and Full Operational Phases), and Decommissioning Phases of the Project.

Cultural heritage is defined as artefacts, monuments, buildings and sites that have a diversity of values including symbolic, historic, artistic, aesthetic, ethnological or anthropological, religious, scientific and social significance (Ref. 16.1). Cultural heritage is an important component of the cultural identity of communities, groups and individuals, and of social cohesion (Ref. 16.2). Cultural heritage includes:

- Tangible cultural heritage, including:
  - Movable cultural heritage (paintings, sculptures, coins, manuscripts);
  - Immovable cultural heritage (monuments, archaeological sites, etc.); and
  - Underwater cultural heritage (shipwrecks, submerged occupation remains, underwater ruins and settlements);

- Intangible cultural heritage (oral traditions, performing arts, religion etc.); and

- Natural heritage (natural sites with cultural aspects such as cultural landscapes, physical, biological or geological formations).

Cultural heritage thus includes both tangible forms of cultural heritage with archaeological (prehistoric), paleontological, historical, cultural, artistic, and religious values, unique features or objects that embody cultural values, and intangible forms of culture such as cultural knowledge and practices of communities embodying traditional lifestyles (Ref. 16.3). Cultural heritage also includes archaeology, which is the scientific study of the physical evidence of past human societies recovered through artefact collection and analysis, and excavation. Physical archaeology includes portable antiquities, monuments, historic buildings, historic landscapes, cemeteries and burial areas. Archaeological sites are a finite, irreplaceable and non-renewable cultural resource and form an intrinsic part of the cultural heritage of the people of the Russian Federation (Refs. 16.4 and 16.5). Throughout this chapter, the term cultural heritage is used to refer to all cultural heritage (tangible and intangible), including archaeology.

Cultural heritage is protected under regional and federal legislation, and by international agreements adhered to by the Russian Federation (Refs. 16.1 to 16.27, and 16.28) (Section 16.6.1). Cultural heritage (including archaeology) is regarded as important due to, but not limited to, the following factors:

- "Archaeological heritage is a fragile and non-renewable cultural resource. Land use is therefore controlled in order to minimise the destruction of the archaeological heritage" (Ref. 16.28);

- Archaeology and cultural heritage are important to civilization and cultural life, therefore they are protected and potentially damaging activities are subject to regulation (Refs. 16.4 and 16.5); and
• Cultural heritage can be important to national, regional and community identity and economic activities (e.g. tourism, crafts, and agricultural practices) (Ref. 16.29).

This chapter aims to identify any known or potential cultural heritage within the Project Area (terrestrial and marine), and to assess potential Project impacts upon this cultural heritage¹. In accordance with International Finance Corporation (IFC) and Organisation for Economic Co-operation and Development (OECD) guidance, this ESIA also considers natural, palaeontological and intangible cultural heritage (Ref. 16.3; Ref. 16.30; Ref. 16.31).

The Project has been designed to avoid impacts on cultural heritage where feasible, while balancing cultural heritage considerations with other environmental and engineering requirements. Where significant cultural heritage impacts remain, this chapter also presents suitable mitigation measures which aim to minimise predicted impacts. A Grievance Mechanism and on-going stakeholder engagement will be implemented as part of mitigation and monitoring measures.

The data and interpretations presented in this chapter are linked to other chapters, including Chapter 6 Stakeholder Engagement; Chapter 7 Physical and Geophysical Environment; Chapter 8 Soils, Groundwater and Surface Water; Chapter 13 Landscape and Visual; Chapter 14 Socio-Economics and Chapter 17 Ecosystem Services.

16.2 Scoping

The scope of the cultural heritage impact assessment for the Project was defined through a scoping process which identified cultural heritage receptors and potentially significant impacts related to the Project. Baseline information which informed the scoping process largely drew on information gathered from studies undertaken for the South Stream Offshore Pipeline, including feasibility, engineering and environmental surveys carried out between 2009 and 2013 (see Section 16.4). Key steps in the scoping process for cultural heritage comprised the following:

• The Projects’ Front End Engineering and Design (FEED) was reviewed to identify activities with the potential to significantly affect cultural heritage objects or receptors;

• Cultural heritage receptors within the Project Area (see Chapter 1 Introduction for definition) were identified through a process of secondary data review and surveys undertaken for the Project (as described in Section 16.4) and professional expertise; and

• A review of relevant national and international legislative requirements and lender requirements to ensure legislative and policy compliance.

¹ This chapter was prepared by qualified and registered cultural heritage professionals. The assessment has been undertaken according to the UK Institute for Archaeologists (IFA) Code of Conduct (Ref. 16.32) and adheres to the high professional standards required of Registered Archaeological Organisations of the IFA. Research, fieldwork and reporting has been undertaken following relevant and locally-applicable elements of the IFA Standard and Guidance for Historic Environment Desk-based Assessment (Ref. 16.33) and IFA Standard and Guidance for Archaeological Field Evaluation (field scanning) (Ref. 16.34).
The Project Area (as described in Section 16.3) contains a range of terrestrial and marine cultural heritage receptors and such features are therefore an important consideration in the ESIA process. Potential impacts upon marine and terrestrial cultural heritage were identified through the Project’s stakeholder engagement activities as being of high importance to the Project (Chapter 6 Stakeholder Engagement).

Terrestrial cultural heritage receptors include archaeological sites from the Bronze Age, burial mounds (kurgan), areas of Antique/Hellenistic, early medieval/Byzantine, medieval and modern occupation, cemeteries, monuments and memorials. The Project Area also has the archaeological potential of other periods, such as early prehistoric tool scatters, hunting and occupation debris and evidence of settlement, farming, land divisions and burials, as well as the potential for historic landscape and woodland features, built heritage (including historic domestic, religious and agricultural buildings, and remains associated with 20th century conflict, including unmarked graves).

In terms of marine cultural heritage, the north-eastern Black Sea region is rich in marine cultural heritage objects or receptors (CHOs) which are fragile and irreplaceable resources and include submerged settlements, shipwrecks and associated nautical material, other anthropogenic structures of historical or archaeological significance, and remains associated with 19th and 20th century conflict. The underlying geological sedimentary deposits of the Project Area have the potential to contain Mesozoic, Miocene and Pliocene marine fossils. Above these fossiliferous deposits is a mantle of Quaternary deposits, soils and coastal marine sediments. There is little potential for the presence of Pliocene hominin and faunal remains, or Pleistocene fossils, due to the absence of refuges such as caves. Marine sediment sequences may provide evidence for past climatic and environmental conditions.

The Project Area does not contain any World Heritage Sites or known tangible or intangible archaeological or cultural heritage features of international significance (nearest World Heritage property is the Western Caucasus natural heritage site (WHS 900), located more than 50 km to the southeast). No intangible cultural heritage (such as specific notable or listed cultural traditions) related to the Project Area, and that could be exploited for commercial purposes, has been identified.

The cultural heritage receptors within the Project Area are identified in this chapter and discussed in terms of their importance and the potential impact that the Project may have on them. Cultural heritage experts met with Project engineers in April 2013 to discuss marine cultural heritage as well as proposed impact avoidance and mitigation strategies.

With reference to the IFC Performance Standards 2012, the Project is not assessed as having any impact on indigenous peoples (Ref. 16.35); further details on the relevance of indigenous people and the Project can be found in Chapter 14 Socio-Economics.

### 16.3 Spatial and Temporal Boundaries

The Project Area is defined in Chapter 1 Introduction and traverses three defined sections: landfall, nearshore and offshore:
• The landfall section is located in a rural landscape approximately 10 km south of the town of Anapa. The eastern part of the route is characterised by vineyards and overgrown former vineyards on hillsides; the western coastal corridor comprises dense mature woodland and vegetation. The coastal segment comprises a cliff edge and scree slope where pipelines will be installed inside microtunnels;

• The nearshore section begins at the exit point of the pipeline microtunnels south of Anapa, approximately 400 m from the coast at a depth of approximately 23 m below sea level, and extends outward to the southwest to a depth 30 m below sea level (Ref. 16.36); and

• The offshore section extends from the end of the nearshore section passing through approximately 225 km of Russian EEZ waters, of which 50 km lie within Russian territorial waters. Within the offshore section are three distinct oceanographic regions that are classified by water depth: the continental shelf (35 m to approximately 150 m), the continental slope (150 m to 1,900 m), and the abyssal plain (1,900 m to 2,200 m) (Ref. 16.37).

The terrestrial and marine cultural heritage Study Areas were determined in accordance with Russian Federation legislation of June 25, 2002 No. 73-FZ (‘On Cultural Heritage Sites’) and Design Documentation State Survey Areas as set out in Agreement No. 240/10 dated 10 January 2010 between Peter Gaz and JSC Giprospetsgaz. This constitutes internationally recognised practice in site survey (Ref. 16.3, para 6; Ref. 16.30, GN12) and was established based on the Project design and consideration of topography and setting (Ref. 16.30, GN3; Ref. 16.38, para 7).

16.3.1 Terrestrial Cultural Heritage Study and Survey Areas

Terrestrial Study and Survey Areas details are presented below:

• **Area of Potential Cultural Sensitivity:** Cultural heritage objects or receptors such as memorials and religious sites have been identified in a wider area, up to 5 km from the centreline of the originally proposed pipeline route, as these may experience traffic and setting impacts during the Construction Phase;

• **General Study Area:** Extends approximately 1 km either side of the originally proposed pipeline route centreline (Ref. 16.39) and was determined in accordance with Russian Federation legislation of 25 June 2002 No. 73-FZ ‘On Cultural Heritage Sites’;

• **Survey Area:** Archaeological and cultural heritage field surveys have been undertaken on a corridor covering 1 km on either side of the originally proposed pipeline route centreline. This included a walkover survey across the Study Area (Ref. 16.40), followed by systematic fieldwalking (artefact collection) and sample test pit investigation of three sites at Varvarovka (ibid; RU-TCH-03; RU-TCH-04; RU-TCH-05); and

2 Setting (cultural heritage) is defined in the Terms to Know and Glossary.
• **Zone of Potential Influence:** Defined as terrestrial areas within 2 km of the originally proposed pipeline route centreline, and ancillary terrestrial aspects including access roads, borrow and disposal areas, construction camps, and unplanned developments induced by the Project including areas impacted by increased traffic movement.

These areas are set out in Table 16.1 and are illustrated in Figure 16.1 Figure 16.2 and Figure 16.5.

**16.3.2 Marine Cultural Heritage Study and Survey Areas**

Marine Study and Survey Areas details are presented below:

• **Area of Potential Cultural Sensitivity:** Cultural heritage objects or receptors such as war graves have been identified up to 2 km from the pipeline route;

• **General Study Area:** This area covered an extensive area including the Black Sea and the surrounding land areas. The General Study Area provided information on the maritime cultures, shipping evolution, shipbuilding trends, and navigation patterns. This information facilitates the interpretation of survey data, which is collected from a narrower Survey Area, centred on the pipeline route;

• **Survey Area:** This area extends over a 2 km wide area centred on the centreline of the originally proposed pipeline route. This area was widened in the proximity of geohazards or other features that were not deemed to be optimal for pipe laying and required a broader corridor to be assessed. The whole survey area, including the sections where it was widened, was subject to geophysical investigations as well as detailed geotechnical and environmental field surveys (Figure 16.7 to Figure 16.9);

• **Zone of Potential Influence:** This zone was defined as the seabed within 150 m either side of the proposed centreline of an individual pipeline. This is based on the avoidance buffer distance chosen by the Project as a design control measure to ensure the avoidance of impacts to cultural heritage objects. The Zone is one of Potential Influence as it is not the case that the entire 150 m wide area could be impacted by Project activities – rather, this area is used to ensure the avoidance of impacts by routing the pipeline away from objects. This avoidance buffer distance was chosen after careful consideration of engineering and design constraints and after a review of commonly-used avoidance buffer intervals for similar marine construction projects. This area is the same for the Construction and Pre-Commissioning Phase, and for the Operational Phase. Specific investigations related to individual sonar anomalies were undertaken in this area; and

• **Anchoring Spread Area:** This area was defined based on the risk of adverse impacts to positively identified and potential CHOs as a result of Project activities involving anchored vessels in the nearshore section of the Project. This was not defined except by depth, and therefore there was no assessment of CHO, nor of impacts or effects.
These areas are described in Table 16.1 and are illustrated in Figure 16.1 and 16.2, where applicable.³

³ Some of the field surveys covered a broader area but still encompassed the Survey Area as defined in this Chapter.
### 16.4 Baseline Data

#### 16.4.1 Methodology and Data

Cultural heritage objects or receptors of relevance to the impact assessment have been defined through a combination of secondary data sources and cultural heritage surveys carried out across the Study Areas.

#### 16.4.2 Secondary Data

##### 16.4.2.1 Desk-based Research

Secondary data sources as follows were consulted as part of this cultural heritage assessment:

- Archaeological studies undertaken by Russian archaeological experts of the Support Foundation for Archaeological Monuments Protection, Moscow and JSC Kuban Heritage, Krasnodar in 2011. The desk-based assessment of primary and secondary archaeological data, including the results of previous archaeological surveys, involved searching source databases, and the study of documentary and archive sources including: the Archaeological Institute of the Russian Academy of Sciences (RAS, Moscow); the Krasnodar State Historic-Archaeological Museum named Felitsin (KSHAM, Anapa); the Department on the Protection, Restoration and Exploitation of Historical Cultural Values (Heritage) of Krasnodar Krai (Anapa); and the State List of Monuments and List of Defined Facilities of Historical Cultural Heritage located in the territory of the resort city of Anapa (Ref. 16.39; Ref. 16.40; Ref. 16.41);

- Secondary data gathering included consultation of the UNESCO World Heritage List (Ref. 16.42), Intangible Heritage Lists (Ref. 16.43) and Database of National Cultural Heritage Laws (Ref. 16.44) for both terrestrial and marine cultural heritage. Analysis of the wider historical, cultural and archaeological context involved consultation of information in relevant digital databases of the Ministry of Culture (Ref. 16.45) and the Office for the Protection, Restoration and Maintenance of Historical and Cultural Values (Heritage) of Krasnodar Region (Ref. 16.46); national and regional databases (Ref. 16.47), bathymetric and shipwreck data (Ref. 16.48); and information from relevant archaeological institutions and museums including KSHAM;

- In order to complement the extensive research of Russian-language secondary sources undertaken during desk-based assessment (Ref. 16.39), relevant international academic

- Consultation of databases on the national and regional framework of Russian archaeology and cultural heritage, including the Council of Europe Compendium of Cultural Policies and Trends in Europe (Ref. 16.58) and the European Heritage Network National Heritage Policies Database (Ref. 16.59);

- Analysis of the wider historical, cultural, archaeological and administrative context involved considering national and regional cultural policies and registers (Ref. 16.45; Ref. 16.46; Ref. 16.47), information on regional art and cultural policy (Ref. 16.60), regional material culture and crafts (Ref. 16.61; Ref. 16.62), and cultural festivals (Ref. 16.63; Ref. 16.64; Ref. 16.65);

- The history and location of land, naval and aerial combat sites in the vicinity of the pipeline corridor were assessed based on key local sources, memorials and international databases, including – Kriegsmarine Service Records (WASt), Lloyd’s Register of Ships/Casualty Returns and Lloyd’s List (Ref. 16.66);

- This study considered the academic context of past and on-going Black Sea archaeological research projects, including wider Black Sea research projects including the Black Sea Trade Project (Ref. 16.67), various projects of the Danish National Research Foundation Centre for Black Sea Studies (Ref. 16.68) and the French Research Institute in Oceanography’s ASSEMBLAGE Project (Ref. 16.69); and

- National mapping was consulted to inform terrestrial field visits and understanding of the wider geographical and topographical context. Satellite imagery (Worldview-2/Ikonos Natural & False Colour Imagery, Oct/July 2011) was assessed for evidence of archaeological features and used in planning site visits. However, substantial portions of the route are under woodland cover or vineyard cultivation, which masks archaeological features from identification through satellite imagery.

### 16.4.2.2 Reporting Methodology

Arbitrary site identification numbers are used for terrestrial cultural heritage, e.g. RU-TCH-01 (Russia, Terrestrial Cultural Heritage, site no. 1). The referencing of marine cultural heritage follows an arbitrary numbering system for cultural heritage objects and also uses sequences of target naming systems established during earlier survey stages. Distances reported in the text in this chapter are measured from the nearest edge of a cultural heritage object to the nearest edge of a Project component or pipeline centreline (terrestrial) or from the nearest edge of a cultural heritage object to the nearest pipeline centreline (marine).
This document has been prepared in accordance with the scope of URS' appointment with its client and is subject to the terms of that appointment. 16.4.2.3 Stakeholder Engagement

Meetings have been held with stakeholders including the Ministry of the Environment, regional, local and rural district administrations, government authorities, community service and infrastructure organisations, landowners, land users, residents of local communities (Gai Kodzor, Sukko, Supsekh, Varvarovka, Rassvet) and tourists, businesses and business associations, marine area users, inter-governmental organisations including the Black Sea Commission, a number of NGOs including international, national, local and community-based organisations (such as Ekurs, KD Group Political Consulting), academic and research organisations (Institute of Archaeology, Russian Academy of Sciences in Moscow).

These are further detailed in Chapter 6 Stakeholder Engagement. For cultural heritage, consultation was undertaken with the Department for Conservation, Restoration and Use of Historical and Cultural Treasures (Heritage) of the Krasnodar Region, the Institute of Archaeology of the Russian Academy of Sciences (IA-RAS) and the Krasnodar State Historic-Archaeological Museum named Felitsin (KSHAM).

The State Archaeological Expert Evaluation noted that the Commission of Experts considered it reasonable and possible to carry out works on the preservation of cultural heritage sites (terrestrial and marine) located in the area of the planned construction (positive conclusion) and recommended the research and design documentation for approval by the state agency for cultural heritage protection (Ref. 16.70; Appendix 16.8). The Project development has been approved by the Department for State Protection of the Cultural Heritage of Krasnodar Krai subject to the implementation of mitigation measures (Appendices 16.9 and 16.10).

Details of stakeholder engagement are set out below.

Terrestrial Cultural Heritage Stakeholder Engagement

Specific cultural heritage stakeholder engagement activities undertaken during the preparation of this assessment include the following:

- The Department for Conservation, Restoration and Use of Historical and Cultural Treasures (Heritage) of the Krasnodar Region was consulted by letter regarding terrestrial and marine cultural heritage in the Study Area (13.02.2011; Ref. 16.71; Appendix 16.3). Their initial response provided information on cultural heritage and zones of protection within the Study Area. It noted that test pit investigations should be carried out as part of a comprehensive baseline investigation of the terrestrial alignment. Depending on the results of investigations, in accordance with Article 36.3 of Federal Law No. 73-FZ (2002), it will be necessary to develop a Cultural Heritage CMP, monument protection measures, fieldwork plan and a mitigation works costing updating that in Proekt documentation (Ref. 16.72; Appendix 16.4);

- Archaeological test pit investigations undertaken in 2011 revealed unstratified archaeological material (ceramics, bone and building materials) at sites Varvarovka 1, Varvarovka 2 and Varvarovka 3. The Krasnodar Krai Heritage Department ("the Department") considered that these sites were not liable to mandatory preservation due to the absence of archaeological stratification and features, and were not eligible for inclusion
on the Unified State Register of the Objects of Cultural Heritage (Monuments of History and Culture) of the Peoples of the Russian Federation. The Department noted that due to the presence of cultural material in the topsoil, and the potential for buried archaeological deposits beneath the soil horizon disturbed by ploughing, Construction Phase groundworks should be subject to an archaeological watching brief in accordance with the current Handbook of Instructions of the Ministry of Culture (Ref. 16.73);

- Krasnodar Krai Heritage Department was consulted with regard to mitigation requirements at the kurgan site (RU-TCH-02) National Monument No 363 (Appendices 16.3 & 16.4). The Department has approved the Project development subject to the implementation of mitigation measures, including the archaeological supervision (watching brief) of excavation and construction work and informing monument protection authorities prior to the start of groundworks (Appendix 16.9);

- The Krasnodar State Historic-Archaeological Museum named Felitsin (KSHAM, Anapa) was consulted by letter regarding terrestrial and marine cultural heritage in the Study Area (13.02.2011; Ref. 16.74; Appendix 16.5);

- The Krasnodar Krai Heritage Department was consulted regarding archaeological surveys for the Varvarovka bypass road area resulting in a terrestrial walkover survey in June 2014 (see Table 16.2). Upon completion of the survey, the Department noted that due to the partial location of the site within the archaeological protection zone of the Varvorovka settlement (medieval, 6th to 13th centuries AD), excavation and construction work should be subject to archaeological supervision (watching brief) in accordance with the current Handbook of Instructions of the Ministry of Culture (Ref. 16.73) and informing monument protection authorities prior to the start of groundworks (Appendix 16.11); and

- During the community public hearing held at the Arin Berd Armenian cultural centre on 12 December 2012, a priest in Gai Kodzor was concerned that noise and vibration from the Russkaya Compressor Station (CS) would have an impact on his church and services. See Appendix 20.1 (Environmental Impacts of Associated Facilities: Russkaya CS) for further information. Further details regarding stakeholder consultation are contained in Chapter 6 Stakeholder Engagement.

### Marine Cultural Heritage Stakeholder Engagement

Potential impacts upon marine cultural heritage were identified through the Project's stakeholder engagement activities as being of high importance to the Project (Chapter 6 Stakeholder Engagement) and meetings were undertaken with the Institute of Archaeology of the Russian Academy of Sciences (IA-RAS) and the Krasnodar State Historic-Archaeological Museum named Felitsin (KSHAM) to determine the scale and scope of the impact assessment, its parameters and the surveys undertaken. The Project held meetings with both organisations in July 2013 to:

- Provide information on the proposed mitigation strategy for marine cultural heritage (i.e. avoidance by a buffer of 150 m);

- Request comments and feedback on the proposed strategy, including any alternative suggestions; and
• For cultural heritage objects that fall within the 150 m buffer and the pipeline route cannot be optimized, discuss proposed mitigation plans (i.e. relocation and/or recovery).

Both IA-MAS and KSHAM agreed with 150 m as being an acceptable distance for avoidance. It was agreed that:

• The two aircraft wings (RU-MCH-001 [B5_S0006] & RU-MCH-002 [RS_651]) receive additional visual survey via remotely operated vehicle (ROV) to identify the type of aircraft and search for any additional remains, as these sites could represent military vessels and possibly war graves. The results of these surveys should then be checked against military records to potentially identify the aircraft and determine its crew and, if warranted, consult with the Russian Association of War Memorials (Ассоциация “Военные Мемориалы”). Recovery of wing RU-MCH-001 was not recommended due to logistical complications (e.g. who will raise the object and where will it be housed), but it could be relocated away from the pipeline construction corridor if it is considered to be at risk from pipe-lay operations;

• The amphora (RU-MCH-003) would be recovered under the supervision of a licensed Russian archaeologist, using a ROV; and

• The wooden shipwreck (RU-MCH-004), would be extremely difficult and costly to recover and conserve and it is best left in place; it was noted that sufficient precautions must be taken to avoid any possibility of anchor damage.

Krasnodar Krai Heritage Department has approved the Project development subject to the implementation of mitigation measures, including the recovery of the amphora (RU-MCH-003) (Appendix 16.10).

16.4.3 Data Gaps

Based upon the review of the data presented in Section 16.4.2 a gap analysis was undertaken between March and May 2012 in order to identify cultural heritage surveys needed to adequately define baseline conditions. The gap analysis noted that:

• The available reporting did not consider results of, or interfaces with, other environmental topics, e.g. soils, geotechnical studies, coastal erosion, bathymetric and geophysical data in an integrated manner;

• Existing data concentrated on known sites, rather than archaeological potential;

• Terrestrial data contained limited and unconfirmed information on current land use, and the reliability of data on the location, date, significance and character of archaeological and cultural heritage sites needed to be verified on the ground;

---

4 Wing RU-MCH-002 lies in deep water on the continental slope at a depth of approximately 1578 m, is located over 162 m from the nearest pipeline.
Chapter 16 Cultural Heritage

- No terrestrial geophysical survey or intrusive archaeological investigation beyond test pit investigation had been carried out, due to the lack of a defined route and terrain constraints (woodland and active vineyards);
- The available reporting did not consider social topics, such as culture and tourism;
- The available reporting made no reference to intangible, natural or palaeontological heritage;
- Limited information on marine non-intrusive geophysical survey or ROV investigation was available at the time of the data gap analysis;
- A survey of the Anchor Corridor had not been undertaken as the area covered by this could not be calculated prior to the selection of the construction contractor and confirmation from the contractor of the area to be used by anchors for the pipe-laying vessel; and
- The reliability of marine survey data was not known. The gap analysis indicated that following the review of the geophysical methods applied and all available reports, further marine archaeological surveys may be required.

Actions arising from the gap analysis included obtaining and translating the full suite of reports prepared in 2011 (Refs. 16.39 to 16.41; Refs. 16.75 to 16.83) and 2012 (Ref. 16.84) for onshore and offshore cultural heritage, including correspondence, raw marine survey data, relevant marine survey methods and subsea imagery (Refs. 16.39 to 16.41; Refs. 16.75 to 16.83; Ref. 16.84); obtaining topographic mapping and information on military or restricted sites at appropriately detailed scales; contacting relevant authorities to establish their requirements; undertaking local consultation; and undertaking a site visit to establish archaeological potential and inform the scope of further survey, design and mitigation works.

After the gap analysis had been completed, further marine surveys using ROV were carried out between June and October of 2012 (see Table 16.3) and a terrestrial walk-over survey was carried out in August 2012. Following these further surveys, the implementation of the gap analysis actions, and the application of the Project design controls and mitigation measures (see Section 16.7), it was confirmed that no further terrestrial archaeological surveys were required. A further marine survey of the Anchor Corridor Area in the nearshore section of the Project would be required but would be undertaken prior to construction by the Project contractor once vessel type and anchor corridor area were known (see Sections 16.4.5 and 16.7).

16.4.4 Primary Data/Baseline Surveys

Surveys undertaken for the Project are detailed in Table 16.2 (terrestrial) and Table 16.3 and Table 16.4 (marine). The results of field surveys are summarised in Table 16.6 (terrestrial and marine) and Table 16.7 (marine). The location of archaeology and cultural heritage sites are marked on the constraints maps, Figure 16.5 (terrestrial) and Figure 16.7, Figure 16.8 and Figure 16.9 (marine). Inventories of cultural heritage sites are contained in Appendices 16.1 and 16.2 (Ref. 16.39; Ref. 16.40; Ref. 16.41).

Georeferencing is sensitive information which is omitted in order to protect sites from illegal looting. In order to protect terrestrial sites from looting, and shipwreck sites from unauthorised diving, the Project has adopted a policy of site confidentiality. This means that the general
locations of sites are mapped, but their exact locations (i.e. coordinates) are not publicly disclosed in this ESIA Report.

16.4.4.1 Terrestrial Surveys

A systematic visual walkover survey of the terrestrial portion of the construction corridor was undertaken up to approximately 1 km either side of the originally proposed pipeline centreline, with a linear separation of 20 to 30 m between archaeologists, noting areas of high topographic potential and observing areas of existing ground disturbance. Field survey was inevitably constrained in areas of dense woodland and steep hillsides. Systematic fieldwalking and artefact collection was undertaken in three vineyards southeast of Varvarovka where the walkover survey had identified artefact scatters (RU-TCH-03; RU-TCH-04; RU-TCH-05). Based on the results of the fieldwalking survey, nine test pits (2 m x 2 m) were excavated in areas of high potential in order to assess the character and integrity of deposits. This work was undertaken according to Russian Federation Permit N1149 for archaeological excavations and surveys (dated 10.11.2010) and Krasnodar region license N56 (dated 16.11.2010) (Ref. 16.40; Ref. 16.41).

A non-intrusive terrestrial walkover survey was undertaken in August 2012. This involved walking the proposed route of the construction corridor and assessing the potential for previously unrecorded archaeological sites or monuments on or adjacent to the Survey Area; visiting designated national monuments to assess their condition and vulnerability; and visiting cultural heritage sites located in within the terrestrial Area of Potential Cultural Sensitivity, noting churches, cemeteries and war memorials. An additional non-intrusive terrestrial walkover survey supplemented by the excavation of test pits was undertaken in June 2014 to fully cover the area of the Varvarovka bypass road.

Terrestrial cultural heritage field studies undertaken are detailed in Table 16.2.

### 16.4.4.2 Marine Surveys and Analysis

Three steps were employed in the identification of marine cultural heritage:

- The geophysical and environmental marine surveys conducted to collect primary data;
- The geophysical and environmental marine survey data interpretation; and
- Geographic Information System (GIS) analysis integration.

The marine surveys were carried out by third-party contractors, while data post-processing and analysis were completed by both the third-party survey contractors and contracted cultural heritage professionals. A description of marine survey methods is set out in Appendix 16.7 (Marine Geophysical, Environmental and Archaeological Survey Methods).

Information on marine CHOs draws on data gathered from previous studies carried out for the Project, including extensive feasibility and engineering surveys performed since 2008. Those studies, which primarily focused on gathering information for geoenvironmental, geotechnical, environmental and engineering purposes, are detailed in Table 16.3. The surveys utilised the following equipment to image and investigate the seafloor: side-scan sonar; multibeam echo.
sounder; sub-bottom profiler; and magnetometer (limited use in shallow waters only). During investigations, objects that exhibited anthropogenic features were located and briefly analysed to determine if further investigations were required.

In addition, marine cultural heritage surveys in 2012 contributed information to this cultural heritage assessment. Fieldwork included a visual inspection of potential CHO targets in the nearshore and offshore sections using a Remotely Operated Vehicle (ROV) equipped with an underwater video camera. These surveys are also noted in Table 16.3.

Desk-based analysis of marine geophysical survey data (ROV and video data) was undertaken by the Support Foundation for Archaeological Monuments Protection and JSC Kuban Heritage in 2011. Further cultural heritage analysis was carried out in 2012 and 2013 to verify the survey data acquired for other purposes, analyse new survey data, and to assess the baseline conditions for marine archaeology CHOs within the Survey Area. Table 16.4 provides details of the analysis carried out and methods used to achieve the required objectives.

### 16.4.5 Data Assumptions and Limitations

Potential cultural heritage occurring outside the defined Study and Survey Areas detailed herein has not been considered within this impact assessment.

---

5 The analysis of CHO was based on pipeline route definition #300512 (dated 30 May 2012).
Cultural heritage data only represents known sites. Additional, presently unknown buried terrestrial or marine archaeological sites may exist that have not been identified through the ESIA investigations.

During the terrestrial surveys, areas of exposed topsoil, subsoil and natural geology were examined for the presence of artefacts or traces of human occupation. These areas include the edges of vineyards, roadside ditches, the sides of dry gullies, eroding cliff faces, upcast spoil from animal burrows and storm-pulled tree root boles. Fields may have subsequently been ploughed, ditches and gullies may have been subject to natural scouring or deliberate clearing, further erosion may have occurred and further trees may have been uprooted. To obtain a fuller coverage, it would be necessary to monitor the Study Area over a number of years.

The woodland in the Study Area is extensive and heavily overgrown in places, which may obscure archaeological sites. Many of the sites that might exist here may only be discovered by chance (hence mitigation measures include archaeological watching brief and chance finds procedure, see Section 16.7).

No detailed analysis of primary medieval and post-medieval historical sources related to the Study Area has been undertaken although place-name evidence has been reviewed.

No research has been undertaken into oral sources, as it was considered that this would be unlikely to reveal any substantial amount of relevant data relating to the Study Area, which contains no settlements within it and has relatively recent vineyard cultivation. The route corridor population is seasonal and transient, mainly using the area for leisure or fishing.

Since the Scoping Report was issued, the community of Rassvet has been identified as a potentially affected Local Community due to confirmation that construction traffic will travel through Rassvet. Therefore, commitments to mitigate potential impacts on Rassvet's cultural heritage have been considered in this chapter.

In the nearshore section of the Project, low sedimentation rates and shallow bedrock offer little to no depositional protection from the existing high energy environment (see Section 16.5.4.2) so any buried remains are likely to be small and scattered. Due the very slow rate of sedimentation on the abyssal plain (see Chapter 7 Physical and Geophysical Environment) in the offshore section of the Project, it is unlikely that previously unknown objects would be identified in that area.

The Anchoring Spread Area in the nearshore section of the Project had not been surveyed at the time of writing and is therefore not included in the assessments and conclusions of this Chapter. An Anchor Corridor Survey will be undertaken by the construction contractor when the area to be used for anchoring vessels has been calculated and confirmed based on identified vessels and the pipelaying method (see Chapter 5 Project Description).
16.5 Baseline Characteristics

16.5.1 Overview

The Black Sea and the Krasnodar Krai are rich in both terrestrial and marine cultural heritage including the archaeological remains of prehistoric *kurgan* burial mounds, ancient towns and settlements, archaeological remains of shipwrecks and associated nautical material. Within the Project Area there is known terrestrial cultural heritage and known and potential marine cultural heritage, including the remains of submerged vessels.

The baseline section of this Chapter presents the historical and cultural context followed by information on the terrestrial and marine known and potential cultural heritage objects identified within the Study Areas as defined in Section 16.3.

The Black Sea has been navigated for thousands of years and served as a nexus for human activity and migration. The subject of scholarly research for the past 50 years, it is unknown when humans first traversed these waters, as archaeological examples of early watercraft have yet to be encountered. Early vessels developed during the Mesolithic to Early Bronze Age (c. 10,000 BC) were relatively simple by today's standards and possibly consisted of dugout canoes, skin boats, and/or rafts. These types of watercrafts are intended for use in localized coastal waters and were probably used to transport a limited number of people for exploration and resource procurement purposes. Remains of such dugout boats have been discovered along the Bulgarian coast that date to the Early Bronze Age (c. 3,200 BC) and represent some of the earliest watercraft to be discovered in the Black Sea.

It was during the Bronze Age that vessels began to increase in size and complexity. Simple canoes gave way to larger, plank-built vessels that were capable of carrying great quantities of goods and merchandise farther along the coast, as trade at this time likely existed between coastal settlements. A boom in maritime activities occurred with the arrival of Greek explorers during Antiquity (c. 700 BC to AD 395). Subsequent colonisation efforts allowed for major trade and production centres began to develop at settlements along every coast of the Black Sea. With the Greeks came their knowledge of seafaring and nautical traditions, which included sail-driven merchant ships and rowed military vessels, traditions eventually utilized by the Romans when they came into power. Maritime trade networks significantly expanded, especially during the medieval and post-medieval periods (395 to 1422), when Mediterranean and other European ships made their way into the Black Sea.

Shipbuilding underwent a profound change at this time; the concept of naval architecture was born and foreign construction conventions and ideas spread through the region. Speed, manoeuvrability, and carrying capacity were traits that shipwrights yearned to perfect, and gradually ships continued to grow in terms of size, grandeur, and intricacy. Seafaring soon became a global enterprise and the Black Sea became a highly attractive region both economically and militarily. Changes to shipbuilding continued, as steam-power and metal-hulled ships began to replace more traditional watercraft beginning in the 19th century. Large scale naval warfare during this time and through the 20th century also contributed to the development of ship design and construction.
A timeline of the north-eastern Black Sea Region is presented in Table 16.5, summarising the regional chronology in order to assist in understanding the area’s historical and cultural context. It is important to note that there is a degree of overlap between some cultural periods, and that local chronological models continue to be developed through the application of scientific dating methods.

Complete.
16.5.2 Archaeological and Historical Context – Terrestrial and Marine

The following archaeological and historical context sets out the background setting of the Project, covering both terrestrial and marine areas. Cultural heritage receptors identified within the Study and Survey Areas are summarised in Table 16.6 and an illustrated inventory is contained in Appendices 16.1 (Inventory of Terrestrial Cultural Heritage Finds) and 16.2 (Inventory of Marine Cultural Heritage Finds).

16.5.2.1 Lower Palaeolithic (c.2,000,000 to 200,000 BP)

During the Lower Palaeolithic, pre-modern humans (Homo erectus) lived in small groups, hunting and gathering from a home base often near a river or cave. Remains include stone tools and fossil bone. Evidence for Lower Palaeolithic activity is very rare, but of great scientific importance. The earliest known hominin site in the region is at Dmanisi, Georgia (located c.680 km southeast of the Project shore crossing), where researchers have found faunal remains dating to the Pliocene (c.5.332 to 2.588 million years before present (Ma)) or earliest Pleistocene Era (c.2.588 to 0.781 Ma), fossilised Homo erectus hominin bones, and Oldowan (c.1.8 Ma) and Acheulean (c.1.4 Ma) stone tools (Ref. 16.85; Ref. 16.86).

Desk based literature review has not identified any terrestrial Lower Palaeolithic sites within the General Study Area. Lower Palaeolithic sites are thus not considered further within this impact assessment.

16.5.2.2 Middle Palaeolithic (c.200,000 to 43,000 BP)

During much of this period, Kuban was a peri-glacial environment, located south of the ice sheets and west of the glaciers of the Caucasus Mountains. The Ice Age glaciations did not reach the eastern shores of the Black Sea, but the colder climate was reflected in the animal species present.

Acheulian material (c.700,000 to 120,000 BP) frequently comprises flint, slate and sandstone tools recovered from river-rolled gravels and eroded river terraces that are not in their original location. Later Acheulian tools, such as scrapers, choppers and chisels have been recovered from inland sites in Krasnodar such as Belaya River, approximately 200 km east of the Project shore crossing) and Labinsk (Bolshaya Laba River, 268 km to the east), the valley of the River Kuban (approximately 60 km to the northeast), and coastal sites such as Kadoshy Cape, near Tuapse (approximately 155 km to the southeast) (Ref. 16.87; Ref. 16.88).

During the Mousterian (120,000 to 30,000 BP), Neanderthals and early humans lived in caves, open-air settlements and temporary hunting camps, in structures built from the bones of mammoths and other large animals. Mousterian tools have been recovered from Ust’-Labinsk, approximately 190 km inland, east of the Project shore crossing in eastern Krasnodar Krai, and archaeological layers have been investigated at the cave sites of Barakaevskaya Monasheskaya and Gubskaya (265 km inland). Tools and the bones of hunted animals including bison, aurochs (extinct cattle), megaloceros (extinct elk), mammoth, wild horse, red deer, wolf and cave bear were recovered from the Ilskaya I and II caves (approximately 95 km east of the Project; Ref. 16.89).
Desk based literature review has not identified any terrestrial Middle Palaeolithic sites within the General Study Area. Middle Palaeolithic sites are thus not considered further within this impact assessment.

16.5.2.3 Upper Palaeolithic (c.43,000 to 12,000 BP)

During the Upper Palaeolithic, anatomically modern humans arrived in Europe and south-west Asia. Tools became increasingly complex and varied, with distinctive regional styles, perhaps indicating the emergence of territorial groups. During intermittent cold periods, the Kuban region lay south of the ice sheets. Mammoth bone was used extensively in constructing huts and tents, and caves and rock shelters were occupied. Large mammals such as reindeer, bison and woolly rhinoceros were hunted using spears.

The earliest evidence for human activity in the vicinity of the landfall section of the Project comprises Upper Palaeolithic stone tools found in the vicinity of the village of Supsekh (located approximately 5 km north of the landfall section of the Project) (Ref. 16.90). Given the distance between defined Upper Palaeolithic receptors and the Project, these are not considered further within this impact assessment.

16.5.2.4 Mesolithic (c.10,000 to 6800 BC)

The retreat of the ice sheets of the Würm glaciation marked the end of the Pleistocene epoch and the start of the Holocene (Ref. 16.86). The climate became more temperate, resulting in the expansion of forest and steppe, and opening up a wider range of food and other natural resources. Mesolithic populations subsisted by semi-nomadic, seasonal hunting and gathering. Bows and arrows, slingshots and composite tools made from small microliths were developed. Grinding stones were used to process plants. Harpoons and net-sinkers have been found, indicating a greater role of fish in the diet than in previous periods.

Stratigraphic and palaeogeographic data indicates that the level of the Black Sea has undergone a range of significant rises and falls, resulting in a changing coastline and the submersion of Pleistocene and early Holocene landscapes (Ref. 16.91). Ancient coastlines have left permanent traces in the form of coastal terraces, relict seafloor features and offshore deposits. During this period the sea levels of the Black Sea were significantly lower than the sea levels of today. Analysis of submerged topography indicates that during the late Pleistocene, sea levels along the eastern and southern shorelines of the Black Sea were, at maximum, approximately 100 m to 155 m below present-day sea levels (Ref. 16.92). Lower sea levels meant greater exposure to the continental shelf for potential human activities, as there was likely to have been extensive exploitation of coastal receptors at this time. Sea levels at the end of the Mesolithic are estimated between 13 m and 15 m below present day levels (Figure 16.3; Ref. 16.93). The rise in sea level up to those of the present day may have slowed agricultural development, forced the migration of affected coastal populations, and extended the period of nomadic ephemeral land use. The drastic rise in sea level is primarily due to regional tectonic faulting and uplifts coupled with the relatively unstable climate oscillations from warm and moist to cold and dry. Archaeological sites from this period were inundated following an increase in sea level. Additionally, many terrestrial Mesolithic sites have been lost due to changes in river courses as a result of a rise in sea level. The potential for inundated Mesolithic sites to exist within the
shallow-water marine environment of the Project Area is classified as low due to high wave-based energy coupled with diminished sedimentation rates and shallow bedrock.

Desk based literature review has not identified any terrestrial Mesolithic sites within the General Study Area. Mesolithic sites are thus not considered further within this impact assessment. No marine Mesolithic sites have been identified within the marine Survey Area.

**Figure 16.3 Sea Level Curve of the Black Sea**

![Image of Sea Level Curve]

### 16.5.2.5 Neolithic and Eneolithic/Chalcolithic (c. 6,800 to 3,200 BC)

During the early Neolithic period, there was a shift towards the domestication of animals and plants. Pottery, textiles and a range of new stone agricultural tools were developed. Neolithic houses, made of mud and wood, were built in small villages. These were often located in river valleys. During the Eneolithic/Chalcolithic period (c. 5,000 to 3,200 BC), copper and gold metalworking was developed.

An overall increase to sea level continued into the Neolithic and Eneolithic/Chalcolithic periods. According to some researchers, the level of the Black Sea rose suddenly around 5,600 BC, increasing from 80 m below sea level, at maximum, to present-day levels, resulting in a
Chapter 16 Cultural Heritage

catastrophic flood which submerged coastal sites, harbours, and river deltas (Ref. 16.94; Ref. 16.95). However, recent research suggests that if the flood occurred at all, water may have risen much less (Ref. 16.96), and that it was not a sudden event (Ref. 16.97). Analysis of sea level curves indicates that several transgression/regression episodes occurred during these periods. During the final Eneolithic through to the Early Bronze Age (c. 4,400 to 3,200 BC), several submerged marine beach facies and estuarine peat layers were found in the Kerch Strait region, connecting the Sea of Azov with the Black Sea (approximately 60 km northwest of Anapa), at depths that ranged from 6.5 m to 5 m below present day sea levels (Refs. 16.98 to 16.105). The Kerch Straits begin approximately 80 km northwest of the Project shore crossing. Sea level oscillations continued throughout this period resulting from global climate changes brought about by planetary orbital shifts, increased volcanism, and regional plate tectonics. Russian sea level curves place the most likely occupied areas during this time along a submerged shoreline between 6 m and 5 m below sea level. The potential for inundated Neolithic and Eneolithic/Chalcolithic sites to exist within the shallow-water marine environment of the Project Area is classified as low due to high wave-based energy coupled with diminished sedimentation rates and shallow bedrock.

Desk based literature review has not identified any terrestrial Neolithic and Eneolithic/Chalcolithic sites within the General Study Area. Neolithic and Eneolithic/Chalcolithic sites are thus not considered further within this impact assessment. No Eneolithic/Chalcolithic sites have been identified within the marine Survey Area.

16.5.2.6 Bronze Age (c. 3300 to 700 BC)

It is not until the late Chalcolithic to Early Bronze Age (c. 3,800 to 3,200 BC) that the sea levels stabilised across the Black Sea and large-scale re-settlement of earlier flooded landforms occurred. By this time sea levels had reached between 8 m to 5 m below present day sea levels at Anapa and the Kerch Strait region (Refs. 16.93, 16.100, 16.105). Sea levels rose up to 5 m above present day levels during the second millennium BC, a total increase of 10 m, before regressing back to approximately 4 m below present day levels c. 700 BC (Ref. 16.93). The potential for inundated Bronze Age sites to exist within the shallow-water marine environment of the Project Area is classified as low due to high wave-based energy coupled with diminished sedimentation rates and shallow bedrock.

During the Bronze Age, farming and technology continued to develop and societies became more complex as social hierarchies emerged. Bronze metalworking and land and sea trade developed. The Bronze Age in Kuban is characterised by the construction of a range of elaborate tombs or kurgan burial mounds.

A series of culture-historical terms have been ascribed to the sequence of Bronze Age activity in the region. These are named after geographical type sites or key characteristics, and include the Maikop Culture, the Catacomb Culture, the Kabardo-Pyatigorsk/North Caucasus Culture, the Circassian Dolmen Culture and the Srubna/Timber Grave Culture. However, the dating of these periods, continuity and change between ‘cultures’ and the development of characteristic monuments and material typologies is still unclear and subject to academic debate, as relatively few modern excavations or scientific dating programmes have been undertaken.
There are Early Bronze Age Maikop Culture settlements (c. 3,000 BC) in the vicinity of Anapskaya (approximately 8.4 km north of the Project construction corridor) and Supsekh (approximately 4.4 km northwest of the construction corridor), with pottery sherds, stone tools and quern stones. Maikop Culture burials with circular stone coverings were identified near Rassvet in 1962-1963, accompanied by grave goods of pottery, musical instruments and bronze weapons (Ref. 16.41, p17). A ritual offering stone from a Maikop sanctuary was found near Anapa (Ref. 16.90, p20-21). No Dolmen Culture settlements (c. 2,500 BC) have been identified in the Anapa area, although dolmens (megalithic monuments) were noted near Natukhaevskaya (approximately 20 km northeast of the Project shore crossing) and in the Sukko valley (approximately 3 km southeast of the Project construction corridor) in the late 19th century (Ref. 16.106). The Catacomb Culture (c. 2000 BC) is represented by a number of kurgan burial mounds in the Anapa area. The North Caucasus Culture is represented by several burials in the Anapa area and by Kabardino-Pyatigorsk type stone axes.

The Late Bronze Age (c. 1,400 to 700 BC) is represented by tools, jewellery and weapons found in the Anapa area, and material from the Sukko valley, Vestnik, Gostagaevskaya and Chekon. A Late Bronze Age settlement has been identified in the vicinity of Supsekh. A number of Late Bronze Age Koban Culture kurgan burial mounds have been investigated. Their construction methods and grave goods may indicate origins in, or contact with, the Central Caucasus.

Evidence of maritime activity begins to appear during the Bronze Age. Archaeological remains of at least five dugout canoes have been found in western Russia that date to this period (Ref. 16.107). These discoveries all come from nearby inland river systems and no dugouts have yet been found near Anapa. Detailed listings of associated artefacts are scarce, but include pottery fragments and stone tools such as grooved chisels and axes. These vessels are likely to have transported resources and trade goods from production centres to settlement sites. Remains of similar watercraft have been found along the western Black Sea coast of Bulgaria; making it possible that canoes were once used all around the Black Sea shores (Ref. 16.108, Ref. 16.109).

No shipwreck remains have yet been discovered in Russia of sea-going vessels of this period, but the Uluburun shipwreck, located off Kas in Turkey (Antalya), can serve as an appropriate comparative example, as it has the most complete hull remains of any Late Bronze Age shipwreck and dates between 1316 and 1305 BC (Ref. 16.110). Notable is the Uluburun’s method of construction, which is known as shell-first, as the hull planks are joined together using pegged mortise-and-tenons. Mortise-and-tenon joinery was a common shipbuilding practice all throughout the Mediterranean from the Bronze Age through to the medieval period (Ref. 16.111).

No Early Bronze Age material has been found within the terrestrial General Study Area.

The remains of Bronze Age to medieval period settlements have been identified during archaeological fieldwalking and test pit investigations at Varvarovka-2 (RU-TCH-04; unstratified site; northern pipeline centreline lies 357 m east of the south-eastern receptor boundary and the core of the site lies 477 m west of the northern pipeline centreline) and Varvarovka-3 (RU-TCH-05; unstratified site; located 557 m northwest of the northern pipeline centreline; the core of the site lies 651 m northwest of the northern pipeline centreline) (Ref. 16.39; Ref. 16.40; Ref. 16.41; Ref. 16.112). There are dolmens located in the Sukko valley, approximately 3 km...
south of the landfall section, and four Bronze Age kurgans or kurgan groups are located on high points between the villages of Varvarovka and Supsekh, located more than 4.5 km north of the landfall section.

No evidence of Bronze Age maritime activity has been found within the marine Survey Area.

**16.5.2.7 Iron Age (c. 900 BC to AD 200)**

The sea levels of the Black Sea experienced minimal change during the Iron Age. The sea level was approximately 4 m below present day levels at the beginning of this period and rose approximately 5 m before dipping again to 2 m below present day levels (Ref. 16.93). This oscillation is attributed to ocean-atmosphere reorganisation associated with the Phanagorian Regression. The potential for inundated Iron Age sites to exist within the shallow-water marine environment of the Project Area is classified as low due to high wave-based energy coupled with diminished sedimentation rates and shallow bedrock.

Agricultural improvements in the Iron Age may have resulted in a shift from nomadic to more sedentary herding, and regional trading groups began to emerge. The ancient historians Herodotus (Ref. 16.113) and Strabo (Ref. 16.114) wrote that the Anapa region was populated by semi-nomadic Scythian tribes known as Maeotians and Sindians, in the 7th to 6th century BC. The nomadic Sarmatians were also recorded in the area in the 6th century BC, and Scytho-Maeotians may have fortified their settlements in response to this threat. The Kuban region was a significant contact and trading zone for agricultural and nomadic peoples, and held an important position in trade between Greeks and Barbarians. The Scytho-Maeotian tribes were gradually Hellenised, importing wine from western Turkey, northern Greece and the northern Aegean islands.

Maritime activities continued to expand in the Iron Age as a result of exploration and trade. The Scythian tribes were primarily horse-breeders and herders and maintained a semi-nomadic way of life up through the 3rd century BC (Ref. 16.115). Little is known of their maritime endeavours or vernacular watercraft, but dugout canoes are likely to have been used for inland water-based travel. Fishing was a popular activity in the northern Black Sea region during the early Iron Age, as evidenced by decorative fish motifs and tools used in fish procurement (such as hooks, line/net weights) (Ref. 16.116). After the arrival of the Greeks in the 6th century BC, it is possible that the Scythians adopted Greek shipbuilding techniques and developed sea-going watercraft, as ancient authors noted the flow of cultural influences between the two groups (Ref. 16.117). The Greeks also brought with them an increased demand for fish, which resulted in a shift from domestic to commercial fishing between the 4th and 2nd centuries BC (Ref. 16.116).

The remains of Bronze Age to medieval period settlements, which may include Iron Age material, have been identified during archaeological fieldwalking and test pit investigations at Varvarovka-2 (RU-TCH-04; unstratified site; northern pipeline centreline lies 357 m east of the south-eastern receptor boundary) and Varvarovka-3 (RU-TCH-05; unstratified site; northern pipeline centreline lies 557 m southeast of the southern boundary of the receptor and 651 m south east of the core of the receptor) (Ref. 16.39; Ref. 16.40; Ref. 16.41; Ref. 16.112).
No other evidence for terrestrial Iron Age activity has been found within the General Study Area, and no evidence for Iron Age activity has been identified within the marine Survey Area.

16.5.2.8 Antiquity (c. 800 BC to AD 370)

The Black Sea in Antiquity follows the same sea level curve as seen in the Iron Age. The sea level was approximately 4 m below present day levels at the beginning of this period and rose approximately 5 m before dipping again to 2 m below present day levels (Ref. 16.93). The potential for inundated Antiquity period sites to exist within the shallow-water marine environment of the Project Area is classified as low due to high wave-based energy coupled with diminished sedimentation rates and shallow bedrock.

Greek colonists settled on the shores of the Bay of Anapa in the late 6th century BC (Ref. 16.89; Ref. 16.118; Ref. 16.119), developing a town on the earlier settlements of Sindos or Limenas Sindikos. Their most significant settlement grew into the polis or city-state of Gorgippia, located on the site of modern Anapa, on the coast approximately 10 km northwest of the Project.

During the Classical period (480 to 323 BC), the city of Gorgippia was located in a key strategic position within the southern limits of the Cimmerian Bosporan Kingdom (Figure 16.4).

Figure 16.4 Greek Cities of the Black Sea
This Ancient Greek kingdom was first settled by Milesians in the 6th century BC, and its capital was at Panticapaeum (now Kerch in Crimea, Ukraine). The port of Gorgippia exported grain, fish and slaves to Athens, the Aegean and the Mediterranean, and imported wine. Trading partners changed over the 4th century; initially, wine was imported principally from Thrace (Mende), then from the Mediterranean, and later from the Aegean island of Kos and Knidos in southwestern Turkey. The fertile hinterland (chora) of Gorgippia was characterised by planned, small satellite villages and farmsteads. Some were fortified, such as the farm of Dzhemet, Rassvet which was excavated in the 1960s and 1970s (Ref. 16.41). The area seems to have been rather thinly populated in comparison with the other chora of the Taman peninsula. South of Gorgippia, villages developed at Supsekh and Sukko.

A number of Gorgippia's necropolises have been investigated. Grave goods in the more central cemeteries demonstrate extensive Greek and Mediterranean culture and imported goods. However, some graves in Gorgippia's central cemeteries also contain local Scythian weapons and Maeotian ceramics. Rural necropolises are different, with distinctive stone structures and grave goods similar to those of the earlier Kobanskaya Culture, and Maeotian pottery. These rural necropolises are found within a radius of 20 km of Anapa, and have been noted at Anapskaya (approximately 8.1 km north of the construction corridor), Rassvet (3.5 km to the north), Usatova Balka (7.5 km to the north), Voskresenskiy (16 km to the north northwest), Usatova Balka (7.5 km to the north), Voskresenskiy (16 km to the north northwest), between Krasnyi and Krasnaya Skala (18.2 km to the north) and also at Tuapse (158 km to the southeast). There are similarities between the moulded pottery and jewellery deposited in the Kobanskaya Culture kurgans in the 8th to 6th century BC and in antique rural necropolises of the 6th to 4th century BC. This seems to indicate a degree of cultural continuity in inland areas beyond the Greek Pontic shores.

In 310/309 BC, united Sarmatian nomadic tribes conquered the steppes on the right bank of the Kuban. The Maeotians' fortifications were dismantled, and their tradition of kurgan burial mounds richly furnished with weaponry ceased. Burial customs changed, and grave goods in kurgans increasingly included amphorae; some are accompanied by opulent Graeco-Sarmatian gold work, imported pottery and textiles.

The Bosporan Kingdom of Pontus became a client kingdom of the Roman Empire in 63 BC, and was briefly incorporated into the Roman province of Moesia Inferior (AD 63 to 68). The Roman kingdom was threatened by local Scythian and Sarmatian tribes, particularly in the 3rd to 4th century AD, when they were displaced by the westward migration of Goths. The city of Gorgippia was destroyed by fire c. AD 238/240, perhaps at the hands of Gothic tribes from the east, or Alans from the west. The Goths and Sarmatian Borani seized Bosporan shipping in AD 255. Gorgippia declined, and was finally abandoned following the Hun invasions of the 370s.

Analysis of submerged beach terraces from this area of the Black Sea reveals that sea levels during this period were between 4.5 m and 2.5 m below present-day levels (Ref. 16.93, Ref. 16.100, Refs. 16.102 to 16.105). In the Kerch Strait submerged Antiquity period wells, amphora, and other structures have been recorded at these depths, indicating possible port settlements. Submerged settlement sites on the Russian Black Sea coast have been identified in nearshore areas off Patrey (Garkuscha, Taman Bay, 70 km north of the Project); Kepy (65 km north-northwest of Anapa), Phanagoria (61 km north), Hermonassa, Taman Peninsula (72 km north), Korokondama, Cape Tuzla (74 km northwest), and Anapa (10 km north) (Ref. 16.120, Ref. 16.121).
When the Greeks reached the Pontic shores, they brought with them an extensive knowledge of sea-based navigation and shipbuilding technology. The warship and merchant ship were the two main types of Greek vessels that existed during this period, but it is the latter that likely made it to the eastern Black Sea region. Merchant ships were deep, broad wooden vessels that used sails as the primary mode of propulsion (Ref. 16.122). This ship type is depicted in decorative motifs from the period and even exists in an archaeological example from the eastern Mediterranean, the Kyrenia shipwreck. Warships, by contrast, were long, narrow wooden vessels with raised platforms and curved posts at both ends (Ref. 16.122). Another primary difference is that warships utilised solely oars for propulsion or a combination of both oars and sails. While characteristically different, it is believed that warships and merchant ships were built in the same fashion; that is, they were built in the shell-first style using an elaborate system of mortise and tenons to secure planking strakes, followed by the insertion of transverse frames as a secondary means of hull strengthening. The Greeks built their vessels using this method throughout Antiquity, while eventually increasing the size of both ship types.

The Romans, by contrast, were not a seafaring people and probably relied on Greek nautical traditions to design and build their vessels. Whilst not much is known about their warships, extensive research has been conducted on the Roman merchant fleet. These vessels were double-ended wooden sailing ships usually with two masts with a cargo capacity ranging from 3,000 to 10,000 amphorae (Ref. 16.122). They were rigged with one large, square mainsail and a smaller, triangular topsail and were fitted with large quarter rudders (i.e. steering oars) at the stern. The same shell-first, mortise-and-tenon construction method used during the Hellenistic period was employed by the Romans.

Regarding trade destinations and goods, the Greeks were more far-reaching than the Romans in their nautical endeavours. From 600 to 323 BC, Greeks sailors made their way from the Sea of Marmara all around the coast of the Black Sea, even reaching the Crimean Peninsula and the Sea of Azov (Ref. 16.123). Hellenistic settlements and city-states developed at eastern sites such as Gorgippia (Anapa, Russia), Phasis (Poti, Georgia) and Dioscurias/Sebastopolis (Sukhumi, Russia) until they came under Roman rule in the 2nd century BC (Figure 16.4). The Romans largely ignored the eastern Black Sea coast, as they instead concentrated efforts to develop settlements on the southern and western coasts. Principal Black Sea exports during this period included grain, salt, fish, and metals, while imports from the Mediterranean included oil, wine, and finished products such as ceramics, metal goods and glassware (Ref. 16.124).

Maritime archaeological finds have been found along the Russian Black Sea coast that date to the Antiquity period. At the Yevpatoria sea port, Lake Donuzlav, Crimea, Ukraine (345 km to the west of the shore crossing and approximately 255 km north of the offshore section), the remains of a ship and its cargo of Heraclean amphora were discovered dating from the 4th to 3rd centuries BC (Ref. 16.120). Vessels from this period have also been found along the Turkish coast, thereby increasing the potential for archaeological finds in the region (Ref. 16.49).

A group of rural villas and farmsteads dating to the Antique period have been identified approximately 1.6 km northwest of Varvarovka (Ref. 16.39; Ref. 16.41). A burial dated to the 6th to 4th century BC is recorded between the villages of Varvarovka and Supsekh, located more than 4 km north of the landfall section of the Project (Ref. 16.39; Ref. 16.41).
There is a designated kurgan located approximately 50 m northwest of the pipeline microtunnel section (RU-TCH-02, National Monument No. 363) (Ref. 16.39; Ref. 16.40; Ref. 16.41). It is dated to the Antique to medieval period. The remains of three farming settlements have been identified located north of the proposed construction corridor during archaeological fieldwalking and test pit investigations. These comprise the sites of Varvarovka-1 (RU-TCH-03; unstratified site; receptor boundary lies 853 m east of the microtunnel exit and the core of the receptor lies 937 m west of the northern pipeline centreline), Varvarovka-2 (RU-TCH-04; unstratified site; northern pipeline centreline lies 357 m east of the south-eastern receptor boundary) and Varvarovka-3 (RU-TCH-05; unstratified site; edge of receptor area located 557 m northwest of the northern pipeline centreline; core of the receptor lies 651 m northwest of the northern pipeline centreline) (Ref. 16.39; Ref. 16.40; Ref. 16.41; Ref. 16.112).

No evidence of Antique period maritime activity has been identified within the marine Survey Area.

16.5.2.9 Medieval (AD 370 to 1475) and Post-medieval Periods (AD 1475 to 1829)

Very minor sea level fluctuations occurred in the Black Sea during the medieval and post-medieval periods. Sea levels were approximately 1 m above present day levels and regressed to modern levels by the 19th century. The potential for inundated medieval and post-medieval sites to exist within the shallow-water marine environment of the Project Area is classified as low due to elevated sea levels during this period, high wave-based energy, diminished sedimentation rates, and shallow bedrock.

During the early medieval period, the region formed part of the Khazar Khanate. It was a major commercial contact zone between northern Europe and Asia (Ref. 16.115). Genoese traders built the fortress of Mapa at Anapa in the 13th century. Raw metals, gold, pearls, amber, textiles and spices were imported, while agricultural products from the Adygei hinterland were exported. These include cereals, cheese, oil and honey, as well as furs and slaves.

Mapa was captured by the Ottoman Empire in 1475. Trade continued and the city was fortified, becoming a strategically important centre of Ottoman culture in the late 17th century. Russia attacked the city and the Ottoman fleet six times between 1788 and 1828 during the Russian-Turkish wars. Anapa was annexed by Russia following the Treaty of Adrianople in 1829.

Minor sea level oscillations continued to occur during these periods, with the last notable regression taking place during the 'Little Ice Age' (c. 1350 to 1850) (Ref. 16.93, Ref. 16.100, Refs. 16.102 to 16.105). Sea levels regressed to 3 m to 2 m below present-day sea levels. Peat layers located at these depths in the Sukhumi Bay region attest to the regression along the north-eastern margin of the Black Sea.

Maritime activity continued to increase along the north-eastern coast of the Black Sea given its strategic location between Europe and Asia. The Khazars maintained control from the Caspian Sea to the Crimean Peninsula to trade salt, wax, fur, leather, and slaves (Ref. 16.115, p74). While watercraft were probably used in river- and sea-based transport of these goods, details on the type or design are lacking. Anchors with stone, lead, and iron stocks dating from the 5th to 7th centuries have been found around the Straits of Kerch, but cultural affiliation has not yet
been determined (Ref. 16.120). Dugout canoes that plied the rivers and coastal areas continued to be used during this time up through the 18th century (Ref. 16.120). The 4th and 7th century shipwrecks discovered at Yassada Island (Bodrum, Turkey) can provide possible parallels for the types of sea-going watercraft used in the Black Sea (Ref. 16.122). These vessels were Byzantine merchantmen and featured construction techniques that could be traced back to the Graeco-Roman tradition of shipbuilding: a shell-first, mortise-and-tenon joined hull. These wrecks also show a gradual departure from this type of construction to one that relied more heavily on the strength of the skeletal framework within the hull, which is known as frame-first construction.

During the late medieval and post-medieval periods, ships in the Black Sea continued to increase in size as interactions with nations outside of the region became more frequent. Recognising the commercial success and growing prosperity of the region, Scandinavian merchant-mercenaries redirected their trade through the Black Sea (Ref. 16.124). Archaeological evidence exists that shows Scandinavian shipbuilding techniques were incorporated into local western Russian vessels during this time, such as clinker joinery and bottom-based construction (Ref. 16.125). There was also extensive military activity throughout the region between the Byzantine, Arabic, and Rus' forces. The Rus' were a Varangian (Viking) group active between late 9th and mid-13th century; Khazar Tmutarakan came under Rus' control in the 10th and 11th centuries.

Italian ships carried Genoese and Venetian traders into the Black Sea starting in the 13th century. The Italians were known for their formidable naval fleet, which included long, rowed galleys, frigates, and smaller warships (Ref. 16.122). Rounder, sail-driven merchantmen with tall sides and bulging prows continued to carry oil, wine, and other goods into the region.

Shipwreck material from this period has been discovered along the Russian coast. A well-preserved Byzantine merchantman was found near the Russian Black Sea resort of Sochi (approximately 230 km southeast of the shore crossing) (Ref. 16.126). Maritime-related artefacts found in the region include anchors, anchor arms, navigation instruments, ship decorations, and ceramics (Ref. 16.120).

Terrestrial cultural heritage comprises two medieval cemeteries located in arable fields on north-facing hillsides east of Supsekh, located more than 4 km north of the landfall section of the Project (Ref. 16.39).

Marine cultural heritage comprises a single ceramic amphora that dates approximately to the medieval period (RU-MCH-003) and an undesignated wooden shipwreck that probably dates from the medieval to post-medieval periods (RU-MCH-004). Both are located within the marine Zone of Potential Influence.

16.5.2.10 Modern Period (1829 to Present)

During the 19th century, the hinterland of Anapa was populated by a cosmopolitan mix of Russians, Ukrainians, Greeks, Germans, Tatars and Armenians. The village of Varvarovka was one of a series of agricultural settlements established by Czech immigrants from Austria-Hungary in the 1870s, at the initiative of agronomist Franz Hejduk. The village of Supsekh was established in the late 19th century. A village called Galkina Shel was established in 1908, and
Armenian refugees from Trabzon settled here in 1915 to 1916. This village was renamed Gai Kodzor in 1925, meaning 'Armenian Gorge' (Ref. 16.127).

Anapa's modern vineyards were first established in the mid- to late 19th century. Following the construction of the railway to Novorossiysk in 1892, coastal resorts, sanatoria and summer tourism developed. After the 1917 revolution, the area became a focus for health treatments and children's holiday camps.

During the Great Patriotic War (1941 to 1945), the Kuban peninsula was occupied by German and Romanian Axis troops between August 1942 and September 1943.

With regard to the marine environment, shipbuilding changed drastically in the modern period. In the early to mid-19th century, metal started to be used more regularly for structural elements and eventually the hull; by the end of the century the majority of ships were being built completely out of iron and steel. Another revolutionary change came with the advent of marine steam engines, and later combustion engines, which had a decisive effect on how ships were built, manned, and operated.

Naval warfare was directly affected by these changes. As vessels became more robust and resilient as a result of their metal hulls, weaponry and ordnance were also redesigned to be more effective. Torpedoes, sea mines, and submarines were used quite extensively in naval combat starting at the end of the 19th century. In the 20th century, aircraft were introduced into military campaigns. During the Great Patriotic War, the nearshore area experienced active marine battles between German and Russian forces, and the Kuban was occupied by Axis troops between 1942 and 1943.

_DS Kalinin, Hero of the Soviet Union and commander of the Second Reconnaissance Detachment Staff of the Black Sea Fleet (1910 to 1943), was killed in action with marines leading a seaborne assault south of the village of Supsekh in May 1943. This event is commemorated with a major memorial erected close to the Anapa-Sukko road, approximately 750 m southeast of the pipeline route centreline (RU-TCH-01, National Monument No. 383). War memorials in the village of Gai Kodzor commemorate Soviet soldiers killed during the Great Patriotic War, and villagers executed at Gai Kodzor in August and December 1942 (RU-TCH-11, National Monuments No. 390 & 391), approximately 5.1 km northeast of the nearest pipeline centreline and connection with the Russian gas network. At Varvarovka, there are monuments to the Soviet marines killed and villagers executed by the invaders in 1942 to 1943, and to countrymen who died in the Great Patriotic War (RU-TCH-09, National Monuments No. 381 & 382), approximately 1.2 km northwest of the northern pipeline centreline. Varvarovka village cemetery (Armenian and Russian cemetery) includes the common grave of Soviet soldiers and civilians killed in 1942 to 1943 (RU-TCH-06, National Monument No. 380), approximately 398 m northwest of the northern pipeline centreline. An MI-6 heavy transport helicopter crashed in 1992 in woodland northeast of Varvarovka, located more than 2.7 km north of the northern proposed pipeline centreline; the site is marked by two memorials (Ref. 16.128).

There are a number of cemeteries associated with the villages to the north of the Project. These comprise Varvarovka village cemetery, a mixed Armenian and Russian cemetery (RU-TCH-06), approximately 398 m north of the northern pipeline centreline and close to the Gazprom Invest Road (permanent access road) and 100 m west of the Project temporary access
road to the microtunnel site; Varvarovka Armenian cemetery (RU-TCH-07), approximately 2.1 km northwest of the nearest pipeline centreline; and Gai Kodzor Armenian cemetery and church (RU-TCH-10), approximately 5.6 km northeast of nearest pipeline centreline.

A new Russian Orthodox church is under construction at Varvarovka (RU-TCH-08), approximately 1.8 km northwest of the northern pipeline centre-line. The Armenian Apostolic Church of St. Sarkis (St. Sergius) at Gai Kodzor was built in 1997 (RU-TCH-12), approximately 4 km northeast of the nearest pipeline centreline, and a new Armenian church of St Gevorg (St. George) has been under construction on an adjacent plot since 2007/8. In the square adjacent to these in Gai Kodzor is a modern Armenian khachkar cross-stone (RU-TCH-13; see Section 16.4.3 Intangible Cultural Heritage for further details).

Two marine sites were identified within the marine Survey Area. These are:

- An aircraft wing with integrated fuel reservoir that dates to the modern period (RU-MCH-001); and
- A metal component belonging to either a marine vessel or aircraft (possibly a wing) that also dates to the modern period (RU-MCH-002).

Desk-based archival research undertaken by Peter Gaz in 2011 and 2012 identified three previously known shipwreck sites: sanitary vessel Dnepr, freight vessel Fabritsius, and the steam scow Gordipiya (Ref. 16.75). The Gordipya is used for recreational diving. In addition, three non-self-propelled bolinder barges, two chaser motor boats, and a number of auxiliary vessels were lost or destroyed in the Anapa region. These objects are located more than 150 m from the nearshore section of the Project.

16.5.2.11 Uncertain Date

Located on the coast west of Supsekh, approximately 3.3 km northwest of the shore crossing, at the base of a cliff, is a series of mortared sandstone walls of uncertain date and function called the ‘Walls of the Sea’. There is speculation that it may be associated with submerged settlement remains (masonry structures) found by divers off the Anapa coast, although they are similar in fabric and construction method to elements of Anapa’s fortifications associated with the Russo-Turkish wars of the late 18th and early 19th centuries (Ref. 16.129; RU-TCH-17).

Marine sites of uncertain date include nineteen potential CHOs originally within the marine Zone of Potential Influence, which will be avoided by 150 m via pipeline re-routing (see Section 16.7).

There is the potential for currently unknown or unregistered CHOs to exist in the nearshore and offshore sections of the Project that lack archaeological context (isolated/chance finds). These may include nautical items that were lost while sailing (e.g. anchors, trade goods), heavy objects jettisoned during inclement weather or conflict, disarticulated ship remains, remains of 19th and 20th century conflict, intentionally scuttled or abandoned material, and un-associated debris or garbage.

16.5.3 Intangible Cultural Heritage

Intangible cultural heritage refers to cultural resources, knowledge, innovations and/or practices of local communities embodying traditional lifestyles (Ref. 16.43). With reference to IFC PS8
paragraph 3 (iii) (Ref. 16.3), the Project does not propose to use any intangible forms of culture for commercial purposes.

The UNESCO Representative List of the Intangible Cultural Heritage of Humanity supports the 2003 Convention for the Safeguarding of the Intangible Cultural Heritage. There is no Russian listed intangible cultural heritage closer than 5,000 km to the Project. 2010 census data indicates that Krasnodar region's multi-ethnic indigenous population includes Russians (88.3%), Armenians (5.5%), Ukrainians (1.6%), Tatars (0.5%), Greeks (0.4%) and other nationalities including Yezidy 6 (3.7%) (Ref. 16.61). Krasnodar's national-cultural autonomy organisations reported in 2012 include German, Jewish, Kurdish, Korean, Tatar, Adyghe (Circassian), Assyrian, Russian Roma, Greek and Belarusan groups (Ref. 16.61). In additional to significant state-supported cultural institutions (Ref. 16.60), the area has a number of amateur associations and clubs such as folk dancing, choirs and orchestral groups, including Russian, Cossack, Greek and Armenian groups (Ref. 16.130). The villages of Varvarovka and Gai Kodzor both have cultural centres.

Traditional Kuban Cossack culture and local folk arts and crafts are being revived with State support, and include weaving, traditional embroidery, pottery, woodworking, basketry, leather manufacture, wool felting and blacksmithing (Ref. 16.62); masters of these arts are honoured with the title 'Master of arts and crafts of Kuban'. Other distinctive local cultural elements include traditional Cossack costume, which dates back to the late 19th century (Ref. 16.61). Gastronomic specialties include local wine (Gai Kodzor Vineyards), as well as Kuban produce including pickles, boiled pork, lard, blinis (pancakes) and pastries (Ref. 16.63).

Socially significant religious and secular events celebrated on the territory of Gai Kodzor, Sukko and Supsekh include national and international festivals, profession day, village days and commemorations of military and historical people and events that have made a significant contribution to the development of Russia and Kuban (Ref. 16.64; Ref. 16.65).

Non-working holidays in the Krasnodar region comprise New Year holidays (1 – 5 January), Christmas/Nativity (7 January), Defender of the Motherland Day (23 February), International Women's Day (8 March), Spring and Labour Day (1 May), Victory Day (9 May), Russia Day (12 June) and National Unity Day (4 November). Other festivals include Theophany/ Epiphany (19 January), Maslenitsa (Pancake Week prior to Great Lent), Easter, International Day for Protection of Children (1 June), Family Day (Saints Peter and Fevronia of Murom, 8 July), Day of Liberation from German-fascist Invaders (Anapa and Anapa region, 21 September), Kuban Family Day (third Sunday in September), the Day of Elderly People (1 October) and Mother's Day (last Sunday in November).

In addition to these holidays and festivals are civic and arts festivals, including 'From Masters of Arts to the Toilers of the Village' national heritage revival festival, the 'Address of Childhood is

6 A Kurdish ethno-religious group with Indo-Iranian roots.
Kuban’ festival of children's artistic creativity, and the ‘For the Glory of Kuban - for the Benefit of Russia’ festival of amateur artistic creativity.

On Victory Day (9 May) and Anapa and Anapa region Liberation Day (21 September) there are rallies, vigils, and wreath- and flower-laying ceremonies at monuments and war memorials. Intangible cultural heritage includes festivals and commemorations associated with war memorials (RU-TCH-06; RU-TCH-09; RU-TCH-11), cemeteries (RU-TCH-06; RU-TCH-07; RU-TCH-10) and churches (RU-TCH-08; RU-TCH-10; RU-TCH-12).

There is extensive tourist interest in Krasnodar's Bronze Age dolmens, some of which are subject to tourist pilgrimages and offerings (Ref. 16.131). No such activities have been observed to be associated with kurgan site (RU-TCH-02) or any archaeological remains located in the terrestrial Study Area.

There is a spring in northern Varvarovka, St. Barbara’s Source (RU-TCH-14; Figure 16.5) where a resident had a vision of a girl in a red dress stretching out her hands to the spring, and held that this was a vision of the village’s patron saint, Saint Barbara (feast day December 17). It is believed that the water from this spring has healing powers. Before the recent construction of Varvarovka Russian Orthodox church, believers met near the spring. An annual procession to the well takes place on the Feast of Theophany (Epiphany/Feast of Lights/Feast of the Manifestation, 19 January), and the water is blessed. Attendees include local parishioners and pilgrims from further afield (Ref. 16.132; Ref. 16.133). St. Barbara’s Source is located approximately 1.9 km northwest of the northern pipeline centreline. There are springs in the villages of Raevskaya/Rajews ki (15.4 km east of the shore crossing) and Semigorye (21 km to the northeast).

The village of Gai Kodzor has an annual festival in May at the modern khachkar cross-stone next to the Armenian Apostolic Church of St. Sarkis (St. Sergius) (RU-TCH-12) and the adjacent Armenian church of St. Gevorg (St. George) under construction since 2007/8 (Ref. 16.130, Ref. 16.134). The khachkar (RU-TCH-13) was carved by Armenian sculptor and stonemason Sergei Danilyan, brought from Armenia and erected in 1992. It depicts two phoenix birds, symbolizing the friendship between the Armenian and Russian peoples. A festival is held at the khachkar in the last week of every May, involving representatives from all communities in the Anapa area. Khachkars or Armenian cross-stones are carved outdoor stone stelae which act as a focal point for worship, as memorial stones and as relics facilitating communication between the secular and divine. Khachkars reach 1.5 m in height, and have an ornamentally carved cross in the middle, resting on the symbol of a sun or wheel of eternity, accompanied by vegetative-geometric motifs, carvings of saints and animals. They constitute a distinctive symbol of the identity of Armenian communities at home and abroad. The symbolism and craftsmanship of khachkars was inscribed on the UNESCO Representative List of the Intangible Cultural Heritage of Humanity in 2010 (Ref. 16.135).

There is a large modern concrete cross on a hill overlooking Supsekh, which was erected in 2005 to commemorate the 60th anniversary of the end of the Great Patriotic War. The area is used as a place of prayer, and the adjacent sign board indicates that it is the property of the Russian Orthodox Church (RU-TCH-15). The site is located approximately 4.5 km north of the Project construction corridor.
A sacred tree was noted west of the road between Sukko and Anapa, north of Varvarovka and distant from the Project (RU-TCH-16). Prayer ribbons and cloth rags are suspended from the branches of a blackthorn tree (*Prunus spinosa*). Sacred trees and groves occur in many cultures across the world (Ref. 16.136). In the Kuban region, the custom may date back to Circassian/Adyghe traditions, which in turn overlie earlier practices (Refs. 16.137 to 16.140).

### 16.5.4 Baseline Summary

The previous section has described the wider archaeological, historical and cultural context. This section focuses on receptors located within the Project Study and Survey Areas (Figure 16.1 and Figure 16.2). Table 16.6 presents an overall summary of terrestrial and marine cultural heritage receptors and the distances to the nearest Project component (terrestrial) or pipeline centreline (marine). Sites in bold italic type are those that are considered to be vulnerable to Project impacts and are carried forward to the impact assessment (Section 16.6.4.2).

**Complete.**

### 16.5.4.1 Baseline Conditions – Terrestrial

As can be seen from Table 16.6, the Project has a moderate to high potential to encounter buried terrestrial cultural heritage remains of settlement and burials dating to the Bronze Age, Iron Age, Antique and medieval periods. The southern part of the 125 m statutory protective perimeter of the kurgan burial mound (RU-TCH-02; National Monument No 363) is crossed by the microtunnels. This mound may be an outlier of a wider group of Bronze Age *kurgans* located to the north, on high ground between the villages of Varvarovka and Supsekh, which are not within the terrestrial Study Area or impacted by the Project.
Fieldwalking and test pit investigation has identified the remains of three settlements of prehistoric, Antique and early medieval date, northwest of the Project (RU-TCH-03, RU-TCH-04, RU-TCH-05; unstratified sites) (Figure 16.5). The status of these sites has been reviewed by the Department of the Protection, Restoration and Operation of Historical and Cultural Values (Heritage) of Krasnodar Region. They were found not to warrant the classification of Cultural Heritage Object or National Monument due to their unstratified character (Ref. 16.112; Appendix 16.8.2). The Project is located beyond the mapped southern extent of these rural settlements, but may encounter peripheral remains. However, the Temporary Access Road runs immediately east of RU-TCH-04 and the Varvarovka bypass road (used by Project during construction only) runs through site RU-TCH-05 and through the protection zone of site RU-TCH-18. An archaeological watching brief will be maintained on all intrusive groundworks, including groundworks in these areas. These sites are not discussed further within this Chapter.

The preservation potential of archaeological remains in the Project landfall section is considered to be low to moderate. Any archaeological deposits along the top edge of the cliff will have undergone coastal erosion processes. Woodland cover east of the microtunnel area is liable to have caused moderate damage to any archaeological deposits due to root growth and root boles left after trees are felled or uprooted. Test pit investigations of the three settlements (RU-TCH-03, RU-TCH-04, RU-TCH-05) noted that occupation strata have been largely removed by vineyard ploughing, and survive only where cut into bedrock. The kurgan burial mound (RU-TCH-02) has been subject to robbing in the past, and it is likely that deposits in the uppermost, central part of the mound are no longer stratigraphically intact.

16.5.4.2 Baseline Conditions – Marine

As shown in Table 16.6, the marine environment has a high potential to feature the following cultural heritage remains: shipwrecks; maritime structures and objects; and remains associated with 19th and 20th century conflict. As a result of the anoxic conditions in the Black Sea, which inhibit corrosion and microbial degradation, the preservation potential for any CHO is greatly enhanced below a water depth of 120 m to 200 m.

Prehistoric and historic occupation areas – such as campsites, resource extraction sites, or settlements – that became submerged as a result of inundation by the Black Sea are not expected in the shallow-water marine environment in the nearshore section of the Project. The low potential for archaeological sites is due to high wave-based energy in these areas that can scatter and destroy submerged cultural material.

Figure 16.9
Compounding this issue are low sedimentation rates and shallow bedrock, conditions that offer little to no depositional protection from these high energy environments. While there is a possibility for archaeological remains to exist, it is unlikely that intact, undisturbed archaeological deposits will be encountered during Project activities in the shallow-water marine environment.

Geophysical and cultural heritage field surveys conducted in 2011 and 2012 discovered a total of 26 CHOs and potential CHOs within the marine Survey Area of the offshore and nearshore sections in Russian territorial waters and EEZ (Table 16.4; Refs. 16.75 to 16.83), three of which were within the marine Zone of Potential Influence. Table 16.7 below and Figure 16.7, Figure 16.8 and Figure 16.9 show the geographical distribution of these targets. The locations of the continental shelf, continental slope and abyssal plain are discussed in Chapter 7 Physical and Geophysical Environment.

*This area is defined as within 150 m of the nearest pipeline centreline.

### 16.5.4.3 Objects within the Zone of Potential Influence - Marine

There are a total of three CHOs located within the marine Zone of Potential Influence i.e. within 150 m of the centreline of any of the four pipelines. These targets (RU-MCH-001 [original designation B5_S0006], RU-MCH-003 [ROV Find_Amphora], and RU-MCH-004 [ROV Find_Wreck]) are positively identified CHOs that range in date potentially from the medieval period to the modern period. The locations of these objects are shown on Figure 16.7 to Figure 16.9, whilst an illustrated inventory is presented in Appendix 16.2. These objects are discussed below.

Object RU-MCH-001 (recorded during original surveys as target B5_S0006) is an aircraft wing with an integrated fuel reservoir that lies at a depth of 78 m on the continental shelf. The object measures 6 m long by 2 m wide, and appears to be primarily constructed of metal. A determination on the identification of the exact aircraft type could not be made from the available data. This object is not an archaeological monument, but is a CHO in accordance with
Federal Law No.73-FZ of June 25, 2002. It is located approximately 56.7 m to the west of the originally proposed centreline of pipeline route #3.

Object RU-MCH-003 (originally recorded as ROV Find Amphora & RS_Cab Ph) is a single ceramic amphora that lies at a depth of 72 m on the continental shelf. This appears to be an isolated find, as there are no other associated objects or materials in the immediate vicinity of the amphora. A determination on the exact cultural affiliation could not be made from the available data, but preliminary analysis suggests it could potentially date to the medieval period. This object is not an archaeological monument, but is a CHO in accordance with Federal Law No.73-FZ dated 25 June 2012. It is located 23.9 m east of the originally proposed centreline of pipeline route #3.

Object RU-MCH-004 (recorded during original surveys as ROV Find Wreck) is a wooden shipwreck that lies at a depth of 442.8 m on the continental slope. The wreck is mostly buried and only one end of the vessel protrudes from the seabed. A determination on the exact cultural affiliation or date could not be made from the available data. This object is not an archaeological monument, but is a CHO in accordance with Federal Law No.73-FZ dated 25 June 2012. It is located 69.7 m west of the originally proposed centreline of pipeline route #1.

The remaining nineteen potential CHO targets within the marine Survey Area (targets R-B1-0029, R-B1-0042, R-B2-0007, R-B5-0006) are potential CHOs that will be avoided by pipeline re-routing (see Section 16.7).

In addition, seven anthropogenic targets that are not CHOs have been identified within 150 m of individual pipelines. Two acoustic targets (Add1 and Add2) in the nearshore section were determined to be modern-period metal structures, likely to be disarticulated marine cranes, in 12 m to 16 m of water. Three magnetic targets (MNS_24/MNS_12, MNS_36, and MNS_40/MNS_37) were identified in the nearshore section as metal anchors and anchor components in 10 m to 12 m of water that date to the modern period. Finally, two acoustic targets (RS_883 and RS_885) on the continental slope were identified as modern-period debris. Target RS_883 is an anchor chain at a depth of 762 m, and target RS_885 is a wooden rod at a depth of 712 m. Although these objects are not CHOs, they are noted so as not to impact Project activities.

16.5.4.4 Objects outside the Zone of Potential Influence but within the Survey Area – Marine

Twenty-two objects are located outside the Zone of Potential Influence and the Anchoring Spread Area, but within the marine Survey Area. Of these, two are aircraft wrecks/remains, one is a shipwreck, and 19 have been identified as potential CHO. This assessment is based on their size (greater than 5 m long), shape, height off the bottom, and acoustic reflectivity in the side-scan sonar images. These are detailed in Appendix 16.2 and illustrated on Figure 16.7 to Figure 16.9.
16.5.5 Critical Cultural Heritage

The Project has the potential to impact critical cultural heritage as defined in IFC PS8 (Ref. 16.3) given the presence of one formally designated site, a burial mound (kurgan) (RU-TCH-02, National Monument No. 363) located approximately 50 m northwest of the pipeline microtunnel section (Section 16.6.5.1).

The Project also has the potential to impact peripheral elements of Bronze Age, Antique and medieval occupation at Varvarovka-1 (RU-TCH-03), Varvarovka-2 (RU-TCH-04) and Varvarovka-3 (RU-TCH-05). As outlined in Section 16.5.4.1 the Department of the Protection, Restoration and Operation of Historical and Cultural Values (Heritage) of Krasnodar Region considers that these features do not warrant classification as Cultural Heritage Objects or National Monuments due to their unstratified character (Ref. 16.112; Appendix 16.4). These sites therefore do not constitute critical cultural heritage as defined in IFC PS8 (Cultural Heritage) (Ref. 16.3).

The nearest World Heritage property is the Western Caucasus natural heritage site (WHS 900), located more than 50 km to the southeast of the landfall section of the Project. The World Heritage Tentative List archaeological site of the Hellenistic city of Tanais (Ref. 5422) is located approximately 270 km to the northeast of the landfall section of the Project, in the Rostov on Don Region (Ref. 16.42).

16.5.6 Palaeontological Heritage

The underlying geology of the area comprises a system of ridges of the Black Sea Caucasus, folded Palaeozoic Era structures (c.541 to 252.2 Ma) and Jurassic (c.201 to 152 Ma) and Cretaceous (c.145 to 72 Ma) period strata (Ref. 16.141; periods defined by the International Commission on Stratigraphy v2013/01, Ref. 16.86). For further details on geology and soils, see Chapter 7 Physical and Geophysical Environment.

The Black Sea region was submerged beneath an ocean during the Mesozoic Era (c.252 to 66 Ma), and it is rich in marine fossils of the Miocene (c.23 to 5 Ma) and Pliocene (c.5 to 2.5 Ma) series, including molluscs, gastropods and bivalves; the fossilised bones of sea turtles and cetaceans have also been found. These deposits are frequently revealed in cliff faces and eroded river and stream channels. Above these fossiliferous deposits is a mantle of Quaternary Period (c.2.6 Ma to present) deposits comprising soils and coastal marine sediments. Sediments may contain climatic and environmental indicators such as diatoms, ostracods and foraminifera (Ref. 16.142). Other fossil bearing deposits are as follows:

- The Palaeozoic basement may contain remains of Carboniferous (c.358 to 323 Ma) marine fossils (conodonts, brachiopods, corals, echinoderms, mollusca, benthonic foraminifera; plant microflora, branches, leaves) and Permian (c.300 to 252 Ma) plant microflora;
- Jurassic strata (c.208 to 146 Ma) may contain fossils of ichthyosaurs and plesiosaurs, fish, bivalves, belemnites, brachiopods, echinoids, starfish, sponges and ammonites; and
- Cretaceous strata (c.146 to 65 Ma) may contain fossil remains of sharks, rays, fish, ichthyosaurs, plesiosaurs, mosasaurs, baculites, marine diatoms (Ref. 16.143; Ref. 16.144).
The Cenozoic Era (c.65 Ma to present) saw the development of mammals, birds, protozoa and flowering plants. Cenozoic fossils from limestone areas include marine fauna such as shells, sea urchins, sharks, marine reptiles, whilst terrestrial fauna included reptiles, birds and mammals.

Pliocene fossil remains of hominin and faunal remains have been found at Dmanisi, Georgia (Section 16.5.2.1). During the Quaternary Period (2.6 Ma to present), a series of repeated glaciations during the Pleistocene Epoch (1.8 Ma to 11,700 BP) saw the extinction of large mammals. The remains of bison, mammoth, megaloceros, aurochs and cave bears have been recovered from the inland Ilskaya I and II caves (Ref. 16.89). During the Upper Palaeolithic cold periods, mammoth bone was used to construct huts and reindeer, bison and woolly rhinoceroses were hunted.

The Project Area does not contain any refuges such as caves, so has little potential for harbouring fossils of Quaternary Period megafauna. However, Quaternary sediments, in particular marine sediment sequences, have the potential to contain evidence for past climatic and environmental conditions, including evidence of sea level changes. Such sediments are present across the entire Black Sea marine region, and are subject to on-going targeted research programmes; deposits in the vicinity of the proposed pipeline route do not present any specific interests or research targets.

16.6 Impact Assessment

16.6.1 Impact Assessment Methodology

The impact assessment methodology specific to cultural heritage, presented in this section, builds upon the general assessment methodology summarised in Chapter 3 Impact Assessment Methodology. The methodology is then developed specifically in relation cultural heritage receptors in relation to impacts arising from the construction, operation and decommissioning of the Project, as is further outlined below.

16.6.1.1 Federal and Regional Legislation

As detailed in Chapter 2 Policy, Regulatory and Administrative Framework, this cultural heritage assessment has taken into consideration national legislation, including the Constitution of the Russian Federation (Ref. 16.4), the Civil Code of the Russian Federation (Ref. 16.7), Foundations of Russian Federation Legislation on Culture No. 3612-1 (Ref. 16.5) and Federal Law of June 25, 2002 No. 73-FZ “On Objects of Cultural Heritage (Historical and Cultural Monuments) of the Russian Federation” (Ref. 16.8).

The Constitution of the Russian Federation establishes the right of every person to have access to cultural values (Clause 44, P. 3) and the responsibility of every person to preserve historical and cultural heritage, to protect monuments of history and culture (Clause 44, P. 3), and to preserve nature and environment, treating natural receptors with care (Clause 58). Federal law states that the cultural heritage (monuments of history and culture) of the Russian Federation is a unique value for the multinational people of the Russian Federation and forms an integral part of the world cultural heritage, and notes that State protection of cultural heritage (monuments
of history and culture) is one of the priorities of the authorities of the Russian Federation, the state authorities of the Russian Federation and local self-government (Ref. 16.4).

Penalties for damage to heritage are set out in the Civil Code of the Russian Federation (Ref. 16.7). The objectives of the Foundations of Russian Federation Legislation on Culture No. 3612-1 (Ref. 16.5) are the maintenance and protection of the constitutional rights of citizens of the Russian Federation for cultural activities, the establishment of legal guarantees for free cultural activities of associations of citizens, peoples and other ethnic communities of the Russian Federation, the definition of the principles and rules of law related to subjects cultural activity and the definition of the principles of state cultural policy, legal rules for state support for culture and guarantees of non-interference in the creative process.

According to Federal Law No. 73-FZ (Ref. 16.8), all cultural receptors and objects of cultural heritage are considered to be the exclusive property of the State, and are protected by the State. Archaeological sites, both formally registered and newly identified, are considered to be objects of cultural heritage of a federal value. According to Article 46 of the Law, individuals and legal entities engaged in business and other activities in the territory of the CHOs are obliged to observe the procedure of use of this territory as established in the Federal Law and Land Laws of the Russian Federation. The broad objective of these regulations is to avoid harm to cultural objects. Article 61 sets out criminal, administrative and other legal liability in the event of violation of the Law.

Other applicable cultural heritage legislation includes:

- Land Code of the Russian Federation (Articles 3, 27, 56, 99) (Ref. 16.9);
- Law of the Russian Federation “On the Subsurface Resources” (Ref. 16.10);
- Urban Planning Code of the Russian Federation (Ref. 16.11);
- Criminal Code of the Russian Federation (Ref. 16.12, Article 164, Article 243);
- Federal Law of 14 January 1993 No. 4292-1 “On the Perpetuation of the Memory of those who Died in Defence of the Fatherland” (Ref. 16.13);
- Federal Law of 12 January 1996 No. 8-FZ “On Burial and Funeral” (Ref. 16.14); and
- Other normative legal acts of the Russian Federation on the protection and use of cultural heritage.

This cultural heritage assessment takes account of Krasnodar regional legislation, including Krasnodar Regional Laws:

- “On Culture” (No. 325, 2000) (Ref. 16.15);
- “On the Objective Composition of Local Immovable Historical and Cultural Monuments Located in the Territory of the Krasnodar Region” (2000) (Ref. 16.16);
- “On Cultural Heritage (historical and cultural) of the Russian Federation located in the Krasnodar Territory” (and subsequent amendments, No. 558-KZ, 06.02.2003) (Ref. 16.17);
- “On Immovable Monuments of History and Culture of Regional Importance”, Situated in Krasnodar Krai (2009) (Ref. 16.18);
• “On the Designated Areas and Protection Zones of Immovable Cultural Heritage (Historical And Cultural Monuments) of Regional and Local Value Located in the Krasnodar Region” (No. 2316-KZ, 19.07.2011) (Ref. 16.19);
• “On Burial and Funeral Business in the Krasnodar Territory” (No. 666-KZ, 04.02.2004) (Ref. 16.20); and
• The Krasnodar Governor’s Resolution “On Amendments to the decree of the Head of Administration of Krasnodar Region of 09.09.2011 No. 975. On the control of the protection, restoration, use and cultural values (Heritage) of the Krasnodar region” (No. 455, 2007) (Ref. 16.21).

16.6.1.2 International Agreements

The Russian Federation has ratified a number of international conventions regarding cultural heritage including various conventions of the Council of Europe (CoE), International Commission on Monuments and Sites (ICOMOS) and the United Nations Educational, Scientific and Cultural Organization (UNESCO), which are set out in Table 16.8.

### 16.6.1.3 Standards and Guidelines for Financing

IFC Performance Standard and Guidance on Cultural Heritage (Ref. 16.3 and Ref. 16.30) aims to protect cultural heritage from the adverse impacts of Project activities and supports its preservation, in accordance with the World Heritage Convention (Ref. 16.1). Its scope includes:
• Tangible cultural heritage with archaeological, palaeontological, historical, cultural, artistic, and religious values;
• Unique natural features or tangible objects that embody cultural values, such as sacred groves, sacred trees, rocks, lakes, and waterfalls;
• Intangible forms of culture proposed to be used for commercial purposes, such as cultural knowledge, innovations, and practices of communities embodying traditional lifestyles; and
• Critical Cultural Heritage - internationally recognised or legally protected cultural heritage areas, including proposed World Heritage Sites. Heritage of communities who use, or have used within living memory, the cultural heritage for long-standing cultural purposes.

In addition, this cultural heritage assessment has been developed with reference to the OECD Common Approaches (Ref. 16.31).

Where further detailed guidance was needed and was not covered by the IFC PS or OECD Common Approaches, the Project has referred to UNESCO and ICOMOS guidance as appropriate.

16.6.2 Impact Assessment Criteria

The criteria used to assess the potential impacts upon cultural heritage sites follow the current international standard for cultural heritage impact assessment, issued by the International Council on Monuments and Sites (Ref. 16.145). It is acknowledged that this current international standard contains much reference to World Heritage, but the assessment tools contained within its appendices are applicable to all cultural heritage. It has been adapted for Russia by applying tiered national standards based on the designation level of known monuments. Cultural monuments are classified according to national standards by type and their significance to Russian culture and history.

16.6.2.1 Receptor Sensitivity

Identified cultural heritage features have been evaluated for their sensitivity in accordance with Table 16.9 which presents a description of receptor sensitivity, (using the categories High, Moderate, Low and Negligible) and highlights relevant applicable legal standards. The terms High, Moderate, Low and Negligible are terms which correlate to the impact assessment matrix which applies to the whole ESIA (Chapter 3 Impact Assessment Methodology)7. Legal standards are detailed in Chapter 2 Policy, Regulatory and Administrative Framework and in Section 16.6.2 Applicable Standards.

7 This is comparable to the categorisations adopted by national standards; the terms High and Major are deemed equivalent. The overall matrix for this ESIA has no ‘Very High’ category, and for this reason the ‘High’ category conflates sites of national and international sensitivity. No World Heritage Sites or proposed World Heritage Sites will be impacted by the Project.
The sensitivity of terrestrial and marine cultural heritage receptors also reflects how vulnerable or robust a site, monument, artefact, assemblage or complex is to damage or destruction by a number of factors, including:

- Natural conditions, such as erosion, flooding, wave movement and chemical deterioration;
- Environmental conditions, such as faunal and floral impacts;
- Human conditions, such as vandalism or interference, recreational use, e.g. vehicle damage, anchor strike; and
- Project-related conditions, including construction and operational impacts.

</tr>
</thead>
</table>
| High      | Changes to most or all key archaeological sites such that the resource is totally altered.  
Changes to key architectural and artistic building elements such that the resource is totally altered.  
Change to most or all key historic landscape elements, parcels or components; extreme visual effects; gross change of noise or change to sound quality; fundamental changes to use or access; resulting in total change to historic landscape character unit.  
Comprehensive changes to setting (refer to the Glossary for definition).  
Major changes to an area affecting intangible cultural heritage activities, associations, visual links and cultural appreciation. |
| Moderate  | Changes to many key materials of archaeological sites, such that the resource is clearly modified. Changes to setting that affect the character of the asset.  
Changes to many key historic building elements, or to the setting of an historic building, such that the resource is significantly modified.  
Change to many key historic landscape elements, parcels or components; visual change to many key aspects of the historic landscape; noticeable differences in noise or sound quality; considerable changes to use or access; resulting in moderate changes to historic landscape character.  
Considerable changes to an area affecting intangible cultural heritage activities, associations, visual links and cultural appreciation. |
## Impact Significance

**Chapter 3 Impact Assessment Methodology** details how impact significance (High, Moderate, Low, Not Significant) can be defined through the consideration of impact magnitude and receptor sensitivity criteria. The impact significance matrix presented in Table 16.13 has been applied in order to assign levels of significance to defined cultural heritage impacts.

16.6.3 Assessment of Potential Impacts: All Phases

16.6.3.1 Impact Sources

The cultural heritage baseline conditions as described in Section 16.5 have the potential to be impacted by various Project activities (as described in Chapter 5 Project Description). This section identifies the activities that are likely to take place during the Construction and Pre-Commissioning and Operational Phases of the Project that have an ability to generate an impact on cultural heritage receptors. The Project activities that have a potential to impact on cultural heritage within the terrestrial and marine Study Areas are discussed in below and summarised in Table 16.14.

The majority of the activities occur during the Construction and Pre-Commissioning Phase of the Project. Operational Phase activities have little potential to impact on terrestrial and marine cultural heritage receptors, as routine operational activities are infrequent, minimally invasive and will take place in areas that will have already undergone ground disturbance during the Construction and Pre-Commissioning Phase of the Project and have had any appropriate design control or mitigation measures implemented. Decommissioning Phase activities are not discussed further in this assessment (see Section 16.9).

Terrestrial Cultural Heritage Impact Sources

Table 16.14 outlined the Project activities that have the potential to impact upon cultural heritage receptors (both known and un-known) during the various Project phases – such activities have the potential to damage or destroy upstanding remains, surface scatters or buried, sub-surface remains.

<td>x</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>
The Construction Phase activities in the landfall section of the Project that have the potential to impact terrestrial cultural heritage are those involving ground clearance or excavation. In particular these may impact upon buried archaeological layers - such activities include:

- Vegetation and land clearance, grading and topsoil stripping;
- Open trench pipe-laying activities;
- Construction of shore crossing microtunnel facilities and foundations for shore pull winches and sheaves;
- Construction of landfall facilities;
- Excavation of foundations, underground chambers and areas for hardstanding formation, building foundations and piling; and
- Ancillary works, including:
  - The preparation of access roads and junction upgrades;
  - The preparation of temporary and permanent drainage channels, soakaways, diversions etc.; and
  - The establishment and use of temporary construction areas, topsoil storage areas, rubble and waste dumping.

It is considered that microtunnelling, which will occur at a depth of approximately 18 m below ground level in the vicinity of kurgan site RU-TCH-02, does not have the potential to physically impact upon archaeological deposits beyond the entry tunnels. This is because archaeological deposits and finds are generally located within the topsoil and subsoil, or cut into the uppermost surface of the underlying superficial geological deposits. In rural locations such as that of kurgan site RU-TCH-02, buried archaeological remains such as inhumations and structures associated with ritual activity are generally found at between 1.5 m and 0.1 m below ground level.

Use of construction vehicles may impact upon cultural heritage receptors through rutting or collision damage, whilst there are risks regarding the unauthorised removal of artefacts or vandalism as a result of increased human access to previously inaccessible areas (such impacts could also occur during pre-construction route surveys).

Some cultural heritage receptors, such as cemeteries, roadside war memorials (e.g. Varvarovka and Rassvet) which are located close to access routes may also be potentially impacted by noise and visual intrusion from Project traffic (which could occur during all Project phases). Visual aspects of setting are addressed in Chapter 13 Landscape and Visual.

As detailed in Section 16.6.3 operational activities have little potential to impact on cultural heritage receptors, as such activities will take place in areas that will have already undergone ground disturbance during the Construction and Pre-Commissioning Phase of the Project and may have had mitigation measures implemented. However, there would remain the potential for the illicit removal of archaeological remains or interference with sites as a result of limited increased movement of people undertaking routine operational tasks (Chapter 5 Project Description).
**Marine Cultural Heritage Impact Sources**

A number of Pre-construction and Construction Phase activities may impact upon the seabed or sedimentation regimes, resulting in potential disturbance of marine archaeological receptors (both known and unknown). The activities include the following and are summarised in Table 16.14:

- Use of underwater survey equipment (via ROV and any towed sensor arrays) during the pre-construction and construction pipeline route surveys (pre-lay, UXO, as-built), and during real time touch down monitoring of pipe-laying activity that may result in seabed contact by ROV strikes and thruster washing;
- Direct disturbance of the CHO as a result of pipe-laying;
- Direct disturbance of CHO as a result of anchoring activities associated with pipelaying. For the majority of offshore pipe-laying work the pipe-lay vessel will be manoeuvred along the pipe-lay route using DP. Anchored vessels can potentially be used in water depths of up to 600 m, although for the Project it is anticipated that anchoring will only be undertaken up to a water depth of approximately 350 – 380 m; and
- Seafloor intervention (which may cause disturbance and changes to erosion and sedimentation regimes) resulting from:
  - Removal of obstacles such as munitions, boulders etc.;
  - Drilling;
  - Dredging;
  - Placement of materials including concrete mattressing, rocks and grout bags; and
  - Pipe-laying and anchoring.

Operational Phase activities which may impact upon marine cultural heritage receptors include:

- Use of underwater survey equipment (via ROV and any towed sensor arrays) during the regular pipeline inspection activities that may result in seabed contact by ROV strikes and thruster washing (ROV sonar and visual surveys along pipeline e.g. initial ROV subsea leak inspection survey, surveys of critical sections, initially annually and subsequently more or less frequently, depending on actual findings); and
- Maintenance and repair to pipelines, which may result in seafloor intervention.

### 16.6.3.2 Project Design Controls

The engineering and design of the Project has incorporated a number of project control measures to ensure impact avoidance and minimisation; these measures are detailed in Chapter 5 Project Description. Design controls for cultural heritage include the following:

- Optimisation of the marine pipeline route to avoid known and potential CHOs by a 150 m buffer. This avoidance buffer distance was chosen after careful consideration of engineering and design constraints and after a review of commonly-used avoidance buffer intervals for similar marine construction projects;
- Microtunnelling for terrestrial cultural heritage;
• Selection of terrestrial transportation routes to avoid sensitive cultural heritage objects or sites; and

• Construction of road by-passes to avoid routing heavy traffic through the communities of Gai Kodzor and Varvarovka. The route of the Project temporary access road was moved further to the east during the detailed design phase of the route, placing a buffer of a gully and vegetation between the road and cemetery RU-TCH-06.

These design controls reduce the risk of any adverse impacts to many receptors, both terrestrial and marine, that have been identified in the previous sections.

Table 16.15 below lists the terrestrial cultural heritage receptors that have been excluded, or scoped out, of the Impact Assessment as a result of the Project design controls.

**Table 16.15 Terrestrial Scoped-out Receptors**

**16.6.3.3 Assessment of Potential Impacts (Pre-mitigation)**

Taking account of the potential Project impact sources as detailed in Section 16.6.3.1, it is possible to define levels of impact magnitude on each of the identified cultural heritage receptors as detailed in Table 16.10 and Table 16.11. Using the impact significance matrix as set out in Chapter 3 Impact Assessment Methodology, it is then possible to define the significance of potential impacts on terrestrial and marine cultural heritage prior to mitigation. Table 16.17 below defines both levels of impact magnitude on terrestrial and marine cultural heritage receptors, as well as defining impact significance.
Where different activities and Project phases are assessed to have different levels of potential impact on a given receptor, the highest level of potential impact has been assigned in Table 16.17.

**Table 16.17 Summary of Predicted Impacts on Terrestrial and Marine Cultural Heritage (Without Mitigation)**

</tr>
</tbody>
</table>

Table 16.17 indicates that a number of cultural heritage receptors are potentially impacted – the sections below consider these receptors in terms of their sensitivity, impact magnitude during the various Project Phases, and the significance of potential impacts (without mitigation).
16.6.3.4 RU-TCH-02 – Burial Mound (kurgan) (Antiquity to Medieval)

- **Description**: National Monument (No. 363). Circular burial mound, 29 m in diameter and 2.97 m high. The centre has been robbed. Surrounded by a 125 m National Monument (No. 363) protection buffer zone;

- **IFC Classification**: Non-replicable tangible cultural heritage (archaeology);

- **Proximity to Project Works**: The microtunnels pipeline cross the 125 m National Monument (No. 363) protection buffer zone at a depth of approximately 18 m below ground level. The monument itself is located approximately 50 m north of the most northerly microtunnel (Figure 16.6); and

- **Sensitivity**: High (National Monument local protection category). The monument is assessed as being of regional value as it can contribute to regional research objectives. It has been subject to an unknown degree of tomb-robbing at some point in the past, the extent of which cannot be determined without intrusive investigation. It is assumed that its integrity is slightly compromised.

- **Magnitude of Impact**:
  - **Pre-construction works** may impact upon the burial mound. It is not considered that vehicle tracking (i.e. wheel damage from vehicles) or collision damage is likely to occur, as the monument is protected by dense vegetation. The site may be impacted by the unauthorised removal of artefacts or vandalism. The magnitude of this potential impact is low;
  - **Construction works** including vegetation clearance along the corridor, works associated with microtunnel insertion c.250 m to the northeast, traffic movements etc. may put the monument at risk of damage. The designated monument protection perimeter defines the extent of the registered monument which would experience changes to setting due to vegetation clearance. The magnitude of this potential impact is assessed as low; and
  - **Operational activities** will give rise to a small increase in the working population accessing the general area, increasing the risk of unauthorised removal of artefacts or vandalism. The magnitude of this impact is assessed as low.

- **Significance of impact**: A potential low magnitude impact during the Construction Phase on this high sensitivity receptor would result in an impact of low adverse significance; and

- **Overall impact**: Overall impact may be local (within the boundaries of the archaeological site), direct (directly affecting the archaeological receptor), permanent and of **low adverse** significance (see summary in Table 16.18).

16.6.3.5 RU-TCH-06 – Varvarovka, village cemetery, Armenian and Russian cemetery

- **Description:** This cemetery lies to the east of Varvarovka village, close to vineyards. The cemetery is extensive and divided into family plots. Includes the common grave of Soviet soldiers and civilians killed in the fighting and executed by the fascist invaders in 1942 and 1943 (National Monument No. 380);

- **IFC Classification:** Non-replicable tangible cultural heritage (historical, cultural, artistic and religious values);

- **Proximity to Project Works:** Cemetery located 398 m northwest of the north-western-most pipeline. Located approximately 10 m south of Gazprom Invest Road and approximately 100 m west of South Stream Transport temporary microtunnel access road. The alignment of the South Stream Transport temporary access road was designed to avoid running close to the cemetery;

- **Sensitivity:** High, as the site contains a National Monument;

- **Magnitude of Impact:** During the Construction Phase, the cemetery and cemetery visitors may be impacted by increased construction traffic movements (noise, visual intrusion and change to setting). Impact magnitude assessed as low. No impacts are anticipated during other Project phases;

- **Significance of impact:** A potential low magnitude impact during the Construction Phase on this high sensitive receptor would result in an impact of moderate adverse significance. Impacts limited to changes to setting, but noticeable differences in noise or sound quality and minor changes to area can affect intangible cultural heritage activities, associations, visual links and cultural appreciation; and

- **Overall impact:** Overall impact will be local (within the boundaries of the cemetery), indirect (affecting cemetery visitors), temporary and reversible (Construction Phase South Stream Transport temporary microtunnel access road) and permanent (Gazprom Invest Road permanent access road) and of moderate adverse significance (see summary in Table 16.19).

16.6.3.6 RU-MCH-001 – An Aircraft Wing on the Continental Shelf (78 m Water Depth) (Modern)

- **Description:** The site measures approximately 7.4 m long by 3.9 m wide, and is primarily constructed of metal. Located in the marine environment in less than 350 to 380 m of
water. It dates to the modern period (20th century). The site does not appear to have any post-depositional anthropogenic disturbance;

- **IFC Classification:** Marine cultural heritage object with historical significance, assessed as being less than 100 years old by experts of the Russian Academy of Sciences;

- **Proximity to Project Works:** This undesignated aircraft wing lies 56.7 m west of pipeline #3;

- **Sensitivity:** The receptor’s sensitivity is assessed as low due to its limited complexity and contextual associations, and low potential for contributing to the understanding of aviation or aircraft construction techniques;

- **Magnitude of Impact:**
  
  - **Pre-construction element of Construction Phase.** Pre-construction route surveys may impact upon the aircraft wing. There is a potential for underwater vehicle (e.g. ROV and AUV) damage resulting from collision, improper tether management fouling the object, or damage from thruster/propeller washing. Magnitude of impact is assessed as moderate, as the site is just over 50 m from the construction corridor;
  
  - **Construction Phase.** It is not anticipated that Construction Phase activities will have a direct impact upon the site. However, the increased activity near to the site increases the risk of potential ROV strikes. As this site is located in less than 350 to 380 m of water, it also has the potential to be impacted by vessel anchoring. Magnitude of impact is assessed as moderate; and
  
  - **Operational Phase.** Operational activities will give rise to a small increase in ROVs accessing the general area, increasing the risk of potential ROV strikes. Magnitude of impact assessed as moderate.

- **Significance of Impact:** A potential moderate magnitude impact on this low sensitive receptor would result in an impact of moderate adverse significance (not significant during the Decommissioning Phase); and

- **Overall Impact:** The overall impact will be local (within the boundaries of the receptor), direct (affecting the receptor), irreversible and of moderate adverse significance (see summary in Table 16.20).

16.6.3.7 RU-MCH-003 – A Single Ceramic Amphora on the Continental Shelf (72 m Water Depth) (Medieval Period)

- **Description:** A single ceramic amphora that appears to be an isolated find, as there are no other associated objects or materials in the immediate vicinity. A determination on the exact cultural affiliation could not be made from the available data, but an examination of the object’s shape suggests it could approximately date to the medieval period (4th to 15th centuries AD);

- **IFC Classification:** Movable marine cultural heritage object with archaeological significance;

- **Proximity to Project Works:** Amphora lying 23.9 m east of pipeline #3;

- **Sensitivity:** The receptor’s sensitivity is assessed as moderate due to the potential for contributing to the understanding of maritime trade interactions and cargoes;

- **Magnitude of Impact:**
  - **Pre-construction element of Construction Phase.** Pre-construction route surveys may impact upon the amphora. There is a potential for underwater vehicle (e.g. ROVs and AUVs) damage resulting from collision, improper tether management fouling the object, or damage from thruster/propeller washing. Magnitude of impact is assessed as high, as the site is less than 50 m from the construction corridor and may require additional geophysical surveys;
  - **Construction Phase.** There is some potential that Construction Phase activities will have a direct impact upon the object. The increased activity near to the site increases the risk of potential ROV damage or unauthorised removal of the amphora. As this site is located in less than 350 to 380 m of water, it also has the potential to be impacted by vessel anchoring. Magnitude of impact is assessed as moderate; and
  - **Operational Phase.** Operational activities will give rise to an increase in ROVs accessing the general area, increasing the risk of potential ROV strikes or unauthorised removal of the object. Magnitude of impact is assessed as low.

- **Significance of Impact:** A potential high magnitude impact on this moderate sensitive receptor (during the Pre-construction Phase) would result in an impact of High adverse significance. Impact significance would be Moderate during the Construction Phase, Moderate during the Operational Phase and Not Significant during the Decommissioning Phase); and

- **Overall Impact:** Overall impact will be local (within the boundaries of the receptor), direct (affecting the receptor), irreversible and of High adverse significance (see summary in Table 16.21).

16.6.3.8 RU-MCH-004 – A Wooden Shipwreck on the Continental Slope (442.8 m Water Depth) ( Probably Medieval to Post-medieval)

- **Description:** An undesignated wooden shipwreck that is mostly buried beneath the seafloor, but has one end protruding up from the seafloor. A determination on the exact cultural affiliation or age could not be made from the available data. An assessment of visible construction features suggests this shipwreck could potentially date from the medieval to post-medieval periods (13th to 19th century);

- **IFC Classification:** Marine cultural heritage object with archaeological significance;

- **Proximity to Project Works:** Shipwreck located 69.7 m west of pipeline #1;

- **Sensitivity:** The receptor’s sensitivity is assessed as high due to its potential for significant contributions to the understanding of early boat construction techniques and maritime trade on the Black Sea. It does not appear to have any post-depositional anthropogenic disturbance;

- **Magnitude of Impact:**
  - **Pre-construction element of Construction Phase.** Pre-construction route surveys may impact upon the shipwreck site. There is an increased potential for underwater vehicle (e.g. ROVs and AUVs) damage resulting from collision, improper tether management fouling the shipwreck, or damage from thruster/propeller washing. The site may be impacted by the unauthorised removal of artefacts during ROV examination of the site as a result of increased human access to previously unknown sites. Magnitude of impact is assessed as moderate, as the site is over 60 m distant from the construction corridor and will likely be exposed to additional geophysical surveys;
  - **Construction Phase.** There is potential that Construction Phase activities will have a direct impact upon the site. Given that this site is located in water depths greater than 350 to 380 m there are no impacts expected as a result of vessel anchoring. The increased activity near to the site increases the risk of potential ROV strikes, thruster washing, or unauthorised removal of artefacts. Magnitude of impact is assessed as moderate; and
  - **Operational Phase.** Operational activities will give rise to an increase in ROVs accessing the general area, increasing the risk of ROV strikes or unauthorised removal of artefacts. Magnitude of impact is assessed as low.

- **Significance of Impact:** A potential moderate magnitude impact on this high sensitive receptor (during the Pre-construction and Construction Phases) would result in an impact of high adverse significance. Impact significance would be **Moderate** during the Operational Phase and **Not Significant** during the Decommissioning Phase; and

- **Overall Impact:** Overall impact will be local (within the boundaries of the receptor), direct (affecting the receptor), irreversible and of **High** adverse significance (see summary in Table 16.22).

16.7 Mitigation and Monitoring

Where the Project involves potential adverse impacts on cultural heritage, that have not been avoided through the application of Design controls (see Section 16.6.3.1), appropriate mitigation measures to avoid, minimise, mitigate and offset these impacts will be applied. The cultural heritage mitigation measures presented in this chapter are based on the policy, regulatory and administrative frameworks as outlined in Chapter 2 Policy, Regulatory and Administrative Framework, as well as national laws and regulations, international conventions ratified by the Russian Federation (Section 16.6.2) and Good International Industry Practice (GIIP).

An Environmental and Social Management Plan (ESMP) will be prepared for the Project before any on-site works begin (see Chapter 22 Environmental and Social Management). The ESMP will set out mitigation and monitoring measures, including those for cultural heritage mitigation and monitoring, as described in the sections below.

Mitigation and monitoring measures will include on-going engagement with the relevant authorities, as needed.

Mitigation measures will be designed and executed following national guidance as set out in Chapter 2 Policy, Regulatory and Administrative Framework:

- Guidelines for the design of archaeological work in areas of national economic construction (Ref. 16.26) and the Handbook of Instructions (HOI) on the Recommendations for Scientific Research, Survey, Design and Production Works, aimed at the preservation of the objects of the cultural heritage (monuments of history and culture) of the people of the Russian Federation (Ref. 16.73);
- Regulations on the Execution of Archaeological Fieldwork (archaeological excavations and surveys) and Compiling Scientific Report Documentation (Ref. 16.27);
- Order of the Federal Service for the Monitoring of Compliance with Legislation in the Area of the Protection of Cultural Heritage ‘Regulation on procedure for issuance of authorizations (permits) for the right of works execution on determination and study of the archaeological heritage objects’ (No. 15, 2011) (Ref. 16.146); and
- Archaeological survey and mitigation works will take account of SNiPs (Russian National Standards - Construction Norms and Rules) related to Engineering Surveys for Construction (SNIP 11-02-96; Ref. 16.22), Engineering and Environmental Investigations for Construction (SNIP 11-102-97; Ref. 16.23) and Pipelines (SNiP 2.05.05-85; Ref. 16.24), as well as
The overarching mitigation measure to prevent any adverse impacts on CHOs, which will be applied throughout the Project life cycle, consists of the adoption by South Stream Transport of a cultural heritage stewardship programme. The objective of such programme is to ensure that all parties involved in the construction, operation and decommissioning of the Pipeline are at all times aware of the importance of cultural heritage and that compliance with national legislation and international conventions is achieved during any activity associated with the Project.

Systematic stewardship of cultural heritage can be ensured throughout the Project life-cycle by developing and implementing a Cultural Heritage Construction Management Plan (CMP) during the Construction and Pre-Commissioning Phase of the Project (see Section 16.7.1) and Operational Management Plans (OMPs) during the Operational Phase (see Section 16.7.2). The Cultural Heritage CMP will be developed and implemented in consultation with the Department on the Protection, Restoration and Exploitation of Historical Cultural Values (Heritage) of Krasnodar Krai. Any archaeological survey and mitigation works will be performed in consultation with the Department on the Protection, Restoration and Exploitation of Historical Cultural Values (Heritage) of Krasnodar Krai.

Appropriate staff training in cultural heritage awareness will be undertaken by staff and subcontractors during all Phases of the Project to assist in the prevention of interference or accidental damage to cultural heritage. The approach to this training will be included within the Cultural Heritage CMP.

A Grievance Mechanism and on-going stakeholder engagement will be implemented as part of mitigation and monitoring measures.

A review of already-collected marine data suggests that chance finds of CHOs are highly unlikely to occur during Project construction and operation activities. A UXO survey will be carried out in advance of pipe-lay activities (see Section 16.7.1.1) to further reduce the possibility that a previously unidentified cultural heritage object, such as a small object that may not have been detected by geophysical surveys, will be encountered during pipe-laying activities. In addition, real time touch down monitoring of pipe-laying activity, using ROV, will be undertaken to confirm the absence of CHO along the pipeline route and to enable a prompt response in case of chance finds.

Should chance finds of cultural heritage objects occur during Project construction activities (including during UXO and pre-lay surveys and site mobilisation activities undertaken prior to construction), the Chance Finds Procedure will be implemented to allow the monitoring archaeologist to record and assess the find, and carry out an appropriate avoidance or mitigation response. The Cultural Heritage CMP will be discussed with the relevant Russian authorities. The relevant authorities will be informed of all chance finds. A Chance Find Procedure appropriate to the Operational Phase of the Project will be developed in advance of the commencement of this Phase. The Chance Find Procedure for all Phases of the Project will be developed in consultation with the Department on the Protection, Restoration and Exploitation of Historical Cultural Values (Heritage) of Krasnodar Krai.
Reducing the risk of looting, vandalism and damage to cultural heritage objects during the Construction and Pre-Commissioning and Operational Phases of the Project will be achieved through implementation of the Cultural Heritage CMP including staff cultural heritage awareness training.

In addition to the implementing the Cultural Heritage CMP the Project will implement specific mitigation measures during the various Project phases. Table 16.23 provides a summary of the cultural heritage mitigation measures – as the principal impacts on cultural heritage will be associated with the Construction Phase, the majority of proposed mitigation measures relate to this phase of the Project. These mitigation measures are explained in more detail in the sections that follow the table.

#### 16.7.1 Mitigation Measures – Construction and Pre-Commissioning Phase

A Cultural Heritage CMP will be developed by South Stream Transport and it will include a Chance Find Procedure. If chance finds are identified during construction, different procedures will be applied depending on the sensitivity of the receptor. The Cultural Heritage CMP will include a tiered approach that will assign responsibility for dealing with the chance find to the appointed watching brief archaeologist, institutional counterpart or national cultural agencies, depending on the significance of the find.

All terrestrial and marine archaeological fieldwork will be approved, permitted and supervised by the authorities. Archaeological works will be undertaken according to the stipulations of the eventual Russian Federation permit for archaeological excavations and surveys and Krasnodar region license (Department on the Protection, Restoration and Exploitation of Historical Cultural Values (Heritage) of Krasnodar Krai).

In addition, the Cultural Heritage CMP will include procedures to ensure the following:

- All known terrestrial and marine cultural heritage receptors will be delineated on digital and paper Project maps and in the Project GIS database, which will be available to the design team and construction contractors;
- Project mapping and GIS will be updated, as necessary, should any chance finds of cultural heritage objects occur;
- Terrestrial receptors will be flagged and protective fencing established, if considered necessary, during ground clearance and during the Construction Phase (Ref. 16.3);
• Archaeological Excavations. Any excavations that may be required as a result of chance finds will be implemented in accordance with applicable laws;

• Conservation. Any post-excavation conservation and analysis, publication, dissemination or finds curation will be undertaken in accordance with Russian legislation and standard national practice (Ref. 16.26; Ref. 16.73);

• A UXO survey will be conducted to strengthen and enhance marine cultural heritage baseline data and further decrease the possibility of encountering a chance find during marine pipe-laying activities. This survey will be conducted in advance of the commencement of pipe-laying works;

• Real-time monitoring of the marine pipe-laying process to ensure that the pipeline is installed at the stipulated distance from any marine CHOAs; and

• A Grievance Mechanism and on-going stakeholder engagement will be implemented.

Potential impacts from the use of ROVs for marine monitoring and surveying activities will be minimised by limiting propeller or thruster washing, proper tether management and avoiding ROV strikes by careful piloting. During surveying and pipe-laying works, archaeological watching briefs will be undertaken to monitor surveying and construction activities.

• At sea, South Stream Transport will ensure that an archaeological watching brief is conducted by a qualified archaeologist to monitor surveying and pipe-laying activities to determine the presence or absence of potential cultural heritage objects and to ensure that known cultural heritage sites are not impacted by surveying and pipe-laying activities, including in all nearshore areas; and

• On land, South Stream Transport will ensure that an archaeological watching brief is conducted by a qualified archaeologist on all areas of terrestrial ground disturbance, including clearance activities, groundworks and excavation works associated with the construction of the terrestrial pipeline route; and all associated temporary and permanent construction areas, access routes and areas of ancillary works, including the Temporary Access Road and Varvarovka bypass road. This constitutes GIIP and IFC PS8 requirements, and was advised in discussions between Peter Gaz and Krasnodar Krai Department for the Protection, Restoration and Exportation of Cultural Heritage Objects of Value and Peter Gaz in 2012-2013 (Appendices 16.3, 16.4, 16.5, 16.9 and 16.11) and by the State Historical-Cultural Expert Evaluation (Ref. 16.70; Appendix 16.8).

Terrestrial and marine archaeological watching briefs will be undertaken by appropriately qualified and experienced cultural heritage professionals approved and permitted by the competent authorities. Specifically, the watching briefs will be undertaken in order to ensure that:

• The avoidance distance of 150 m for known marine CHOAs is adhered to during marine pipe-laying;

• The agreed mitigation measures are appropriately implemented to ensure the prevention of damage to presently known marine CHOAs from the use of ROVs or other surveying and construction activities; and
- The procedure for chance finds, as outlined in the Cultural Heritage CMP, and detailed in the Contractor’s CMP, is appropriately implemented.

Specific mitigation measures that will be applied to identified terrestrial receptors include the following:

- Terrestrial site RU-TCH-02 (Kurgan burial mound) will be protected by flagging and/or fencing and security provided, if required.

Specific mitigation measures that will be applied to identified marine receptors include the following:

- Aircraft wing RU-MCH-001 lies within 150 m of the centreline of one of the pipelines and cannot be avoided by the 150 m avoidance distance. The wing will be subject to further identification and, if warranted, observation, lifting to surface or relocation with the recording of new coordinates of the object. If the object remains in place, use of avoidance buffering of approximately 60 m (due to geotechnical constraints);

- Amphora RU-MCH-003 lies within 150 m of the centreline of one of the pipelines and cannot be avoided by the 150 m avoidance distance. It will be recovered by lifting it to the surface prior to the start of construction;

- Wooden shipwreck RU-MCH-004 lies within 150 m of the centreline of one of the pipelines and cannot be avoided by the 150 m avoidance distance. The wreck will be further investigated via ROV as part of the pre-construction UXO survey and details recorded. Avoidance buffering of approximately 70 m (due to geotechnical constraints) will be implemented; and

- Relocation and recovery measures will be established in consultation with the Russian Ministry of Culture and implemented using the best available techniques. The areas adjacent to these objects (i.e., a radius of 150 m to 200 m) will also receive high-resolution survey and documentation prior to recovery activities to ensure that no additional cultural material is present. Nationally and internationally recognised practices for the protection, field-based study and documentation of the cultural heritage will be implemented.

Where anchoring vessels are used for Project activities, there is a potential to impact marine cultural heritage sites. The survey data that has been used to identify the CHOIs described in this study covers an approximately 2 km wide corridor. In water depths in excess of approximately 100 m the anchors could be laid outside the currently surveyed area, potentially impacting currently unknown objects.

- An Anchor Management Plan will be developed to enable marine works to proceed in a manner that safely avoids marine archaeological sites in water depths where anchoring will take place by placing the anchors at a distance of no less than 150 m from currently known receptors and any that are identified as a result of the anchor corridor survey. The Anchor Management Plan will be developed by the chosen contractor; and

- A survey of the Anchoring Spread Area will be conducted by the pipeline construction contractor using high resolution side scan sonar. The survey will record data at high enough resolutions to discern CHOIs, including those observed during prior geophysical surveys of the pipeline corridor. Side scan sonar will overlap and provide 100% coverage of the sea
floor. Based on the CHO/potential CHO that are identified anchor avoidance buffers of 150 m will be established to ensure no associated anchoring impacts (drags, sweeps or drops) will occur.

16.7.2 Mitigation Measures – Commissioning and Operational Phase

As no significant intrusive work will be carried out on the pipelines during their operation no significant impacts are expected. However, in the nearshore and offshore sections of the Project, inspection and maintenance activities that may involve the use of ROVs may be required. In such cases, the mitigation measures will be as per the Construction Phase and will include the limitation of ROV propeller or thruster washing, proper tether management and avoidance of ROV strikes by careful piloting. On land, similar measures as per the Construction Phase will be implemented to address any potential impacts from inspection and maintenance activities. As during construction, Project mapping and GIS will be updated, as necessary, should any chance finds of cultural heritage objects occur. A Grievance Mechanism and on-going stakeholder engagement will be implemented as part of mitigation and monitoring measures.

A Chance Find Procedure appropriate to the Operational Phase of the Project will be developed in advance of the commencement of operation of the pipelines and will be included in the Operational Management Plans. The Operational Management Plans will describe environmental and social mitigation, management and monitoring requirements and actions in relation to normal operating conditions and planned maintenance, minor repairs and minor incidents.

16.7.3 Monitoring Requirements

As set out in Chapter 22 Environmental and Social Management, a Cultural Heritage CMP would be implemented throughout the Project Construction and Pre-Commissioning Phase with OMPs implemented during the Operational Phase, as appropriate. Monitoring requirements will form part of the Cultural Heritage CMP and any Operational Phase Plans, including Chance Finds Procedures and staff cultural heritage awareness training.

Monitoring requirements identified during the Construction and Pre-Commissioning Phase comprise:

- Archaeological watching briefs on terrestrial groundworks;
- Archaeological watching briefs on marine works, including the pipe-lay vessel and nearshore approaches;
- Monitoring of the seafloor/CHO condition will be undertaken as part of the real time touch down monitoring of the material placement, pipe-laying activity and during the as-built pipeline route survey. This monitoring will include specific monitoring of cultural heritage objects RU-MCH-001 and RU-MCH-004, all of which lie within the marine Zone of Potential Influence, in order to confirm that the objects have been avoided during the pipe-laying process. The monitoring will also confirm that all other CHOs have been avoided by the specified 150 m buffer zone; and
- Where technically feasible, the sediment load baseline will be established via multi-beam echo sounder and side-scan sonar survey, as well as visual observation of the sea surface, and sampling to establish the suspended matter content and particle size distribution of matter within marine horizons (surface, thermocline, benthic and seabed), as part of the sea water monitoring programme and in accordance with Russian regulations (Refs. 16.147 to 16.150).

Monitoring requirements have been identified for the Operational Phase and comprise:

- Where a CHO is located within 150 m of the centreline of any one of the four pipelines (i.e. a currently unknown CHO discovered during the construction activities that could not be avoided by re-routing of the pipeline), monitoring of the CHO condition and seafloor between the CHO and the pipeline by ROV in the course of sonar and visual inspection and maintenance surveys during the Operational Phase. The purpose will be to monitor the condition of cultural heritage sites and their preservation contexts in case the Project gives rise to any unanticipated physical, chemical or environmental changes, and if so, to allow for the early identification of these changes and for corrective measures to be implemented.

16.8 Residual Impact Assessment – All Phases

Table 16.24 (terrestrial) and Table 16.25 (marine) present a summary of the potential residual impacts on cultural heritage receptors during the Construction and Pre-commissioning Phase and the Operational Phase respectively, following the implementation of the mitigation measures detailed in Section 16.7.

16.8.1 Terrestrial Cultural Heritage

Table 16.16 presented details of potential cultural heritage impacts without mitigation. Table 16.24 provides details of mitigation measures to be undertaken for those receptors that are potentially impacted by the Project, and post-mitigation levels of residual impact significance following the application of mitigation measures. For each of the receptors identified, the post-mitigation impact significances in Table 16.24 were determined.

</tr>
</tbody>
</table>

**Complete.**

During the Construction and Pre-Commissioning Phase:

- Potential adverse impacts:
  - Without mitigation, low adverse impacts are predicted for the burial mound (kurgan) (RU-TCH-02). The site will not be directly impacted by construction works as it will be preserved in place by microtunnelling. The proposed microtunnels will pass approximately 18 m below the receptor, but within the 125 m buffer area that surrounds it. The insertion of the microtunnels will avoid disturbance of non-geological deposits, and will not impact the topsoil, subsoil, and surface of natural horizons, which are the only strata liable to contain archaeological features or finds. In consultation between Peter Gaz and the Krasnodar Krai Department for the Protection, Restoration and Exportation of Cultural Heritage Objects of Value, the Department indicated that it would be best to avoid impacts on the monument and to protect and preserve the monument in situ. Mitigation will include Cultural Heritage Awareness Training, the implementation of site protection measures such as demarcation with suitable materials following the site warning colour codes, chance finds procedures and traffic control measures, including an appropriate fixed track policy, via the Cultural Heritage CMP. Following mitigation the residual impact is assessed as Not Significant.

  - The mound will be protected prior to any groundworks to prevent accidental damage. Flagging or fencing and signage (to be determined by the permitting authorities) will be subject to regular inspections and maintenance.

  - Without mitigation, Varvarovka village cemetery, Armenian and Russian cemetery (RU-TCH-06) may experience moderate adverse impacts. The route of the South Stream Transport temporary microtunnel access road has been designed to minimise impacts by implementing a road layout which moves construction traffic away from the cemetery area and its immediate surroundings. However, the Gazprom Invest permanent road will run immediately north of the cemetery, following the course of an existing road.
Mitigation will involve the preparation and implementation of the Traffic Management component of the Russian Landfall CMP, which will contain measures to manage traffic in proximity to the cemetery, and the Cultural Heritage CMP. Following mitigation, the residual impact is assessed as **Low**.

There is potential for unknown and unregistered buried archaeological remains and stray finds to be present within the construction corridor of the Project. The potential Project impact on such features may range between moderate and high adverse, depending on the character and sensitivity of the remains and their location. In accordance with legislation and to mitigate for the disturbance of potential sites, an archaeological watching brief will be conducted on all areas of ground disturbance. Mitigation will also involve the development and application of a Cultural Heritage CMP including Chance Finds Procedures (CFP) and appropriate staff training in cultural heritage awareness.

- **Potential beneficial impacts:**
  - The information gathered during the watching brief and any further investigations undertaken by Russian archaeologists may enhance the current archaeological knowledge and understanding of the region.

No impacts on terrestrial cultural heritage are expected during the Operational Phase.

In conclusion, after mitigation the residual impact on terrestrial cultural heritage is assessed as **Not Significant**.

### 16.8.2 Marine Cultural Heritage

For those marine receptors that are indicated to be potentially impacted by the Project in Table 16.17, applicable mitigation measures will be applied. Table 16.25 provides details of mitigation measures to be undertaken, and post-mitigation levels of residual impact significance.

#### Table 16.25 Construction and Pre-Commissioning Phase Residual Impact (Marine Cultural Heritage)

**Continued...**
Table 16.25 indicates the following:

During the Construction and Pre-Commissioning Phase:

Potential adverse impacts:

- Without mitigation, impacts of moderate significance are predicted for the aircraft wing (RU-MCH-001). This site can be impacted by pre-construction activities and Construction Phase works based on proximity to the nearest pipeline centreline. The proposed pipeline route cannot be optimised to accommodate an avoidance buffer of 150 m in this area due to geotechnical constraints. Following mitigation through further survey investigation and, if warranted, relocation or avoiding the site by a buffer of approximately 60 m (due to geotechnical constraints, the significance of the residual impact is assessed as being Low Adverse;

- Without mitigation, impacts of high adverse significance are predicted for the ceramic amphora (RU-MCH-003). This site can be impacted by pre-construction activities and Construction Phase works based on proximity to the nearest pipeline centreline. The proposed pipeline route cannot be optimised to accommodate an avoidance buffer of 150 m in this area due to geotechnical constraints, and therefore mitigation through archaeological recovery will be undertaken. Following mitigation through recovery, the significance of the residual impact is assessed as being Moderate adverse due to the removal of the object from its context;

- Without mitigation, impacts of high adverse significance predicted for marine site RU-MCH-004 (wooden shipwreck). This site may be impacted during the pre-construction activities and Construction Phase works based on proximity to the nearest pipeline centreline, and therefore mitigation through avoidance will be undertaken. The proposed pipeline route cannot be optimised to accommodate an avoidance buffer of 150 m in this area due to geotechnical constraints, but the site will be avoided by a distance of approximately 70 m. Following mitigation through avoidance controls (such as avoiding ROV strikes, minimising propeller or thruster washing, tether management, use of ultra-short baselines and acoustic tracking), the application of an Anchor Management Plan, sediment monitoring, ROV-based monitoring, CFP and staff training, the significance of the residual impact is assessed as being Moderate adverse; and

- Without mitigation, during the Construction and Pre-Commissioning Phase there is the potential for currently unknown cultural heritage to be impacted by the Project resulting in potential Low to High adverse impacts, depending on the importance of the find. Should
any currently unknown CHO be identified, the mitigation measures outlined in Section 16.7.1 will be applied and any residual impacts are anticipated to be Low.

Potential beneficial impacts:

- Information gathered from the watching brief and any further investigations, which will be supervised by Russian archaeologists, may enhance the current knowledge of maritime archaeology in the Russian Sector of the Black Sea.

Operational Phase impacts are summarised in Table 16.28.

Potential adverse impacts:

- Without mitigation, during the Operational Phase there is the potential for as yet unknown cultural heritage to be impacted by the Project resulting in potential Low to High adverse impacts, depending on the character and sensitivity of the find and its location. Should any currently unknown CHO be identified, mitigation measures outlined in Section 16.7 will be implemented where possible and any residual impacts are anticipated to be Low.

Potential beneficial impacts:

- Where a CHO is located within 150 m of the centreline of any one of the four pipelines, periodical monitoring of the CHO condition and seafloor between the CHO and the pipeline by ROV in the course of sonar and visual inspection and maintenance surveys will provide longitudinal data on the condition of CHOs.

In conclusion, after mitigation, the residual impact on marine cultural heritage is assessed as Low.

**16.8.3 Summary of Cultural Heritage Residual Impact**

Tables 16.26 (terrestrial) and Table 16.27 (marine) provide a summary of potential residual impacts upon cultural heritage receptors arising from the Project during the Construction and Pre-Commissioning Phase following the implementation of mitigation measures detailed in Section 16.7.1. Table 16.28 provides a summary of the potential residual impacts upon cultural heritage receptors arising from the Project during the Operational Phase following the implementation of mitigation measures defined in Section 16.7.2.

16.9 Unplanned Events

An unplanned event, such as the controlled detonation of a UXO, an ROV strike, the sudden abandonment of the pipeline, during construction, as a result of emergency situations, or a major pipeline breach and pressure loss during operation, may result in damage to or destruction of submerged archaeological material. The magnitude of this impact is assessed as high, and the significance is assessed as moderate to high adverse, depending on the sensitivity of the receptor. However, the likelihood of this event occurring is very low and therefore, for the purposes of this assessment, such potential impact has been discounted.

It should also be noted that during the Construction and Operational Phases, changes in the seafloor due to environmental conditions could have the potential to impact known and as yet unknown cultural heritage, resulting in potential Low to High adverse impacts, depending on the significance of the cultural heritage object.

Appropriate unplanned event contingency planning will be undertaken that minimises the likelihood of low probability events occurring, as well as minimising event consequences (Chapter 19 Unplanned Events).

16.10 Cumulative Impacts

The cumulative impact assessment considers the Project within the context of other development projects in the local Study Area and the wider regional area. The assessment is presented in Chapter 20 Cumulative Impacts.

16.11 Conclusions

The Project will generate beneficial impacts during all phases of the Project:

- Further survey work will be undertaken of the following marine sites: the wooden shipwreck (RU-MCH-004) and the aircraft wing (RU-MCH-001) as part of the pre-construction activities;
- A ceramic amphora (RU-MCH-003) will be recovered and if warranted, the aircraft wing (RU-MCH-001) will be relocated; and
- The conditions of any positively identified marine CHOs (including any chance finds) in close proximity of any pipeline will be monitored throughout the life cycle of the Project during routine inspection and maintenance works.

Information gathered from further investigations and on-going monitoring may enhance the current knowledge of terrestrial and maritime archaeology in the Russian Sector of the Black Sea.

With regard to potentially adverse effects the Construction and Pre-Commissioning Phase of the Project has the greatest potential to impact terrestrial and marine cultural heritage receptors.
• Potential impacts to terrestrial cultural heritage designated *kurgan* burial mound RU-TCH-02 are avoided as the result of the design control of microtunnelling which places the pipelines approximately 20 m below the receptor;

• Potential impacts on terrestrial cultural heritage will also be mitigated by archaeological watching briefs (monitoring), application of Cultural Heritage CMP, Chance Find Procedures and Cultural Heritage Awareness Training and, if warranted, archaeological excavation and the implementation of the Traffic Management component of the Russian Landfall CMP, including a fixed track policy. These mitigation measures will reduce operational impacts to cultural heritage receptors to **Not Significant**;

• Potential impacts to known marine cultural heritage receptors are avoided as a result of the design control of re-routing the pipelines to ensure a minimum separation distance of 150 m from these known and potential CHOs. Sites include potential CHO (B1_S0002; G-B1-0006; RS_21; RS_35; RS_394, RS_538; RS_942; RS_943, RS_993; R-B5-0010; R-B1-0010; R-B1-0011), potential shipwrecks (RS_77; RS_871; R-B1-0008), a shipwreck (RS_872) and a German Messerschmitt Bf 109 (Me 109) Aircraft (CHO) (RS_190);

• Potential impacts to known and potential marine CHOs in the anchor spread area will be mitigated via the Anchor Corridor Survey and Anchor Management Plan;

• Potential impacts on marine cultural heritage will also be avoided by real time touch down monitoring during pipe-lay and the as-built survey along with careful management and piloting of ROVs; and

• Potential impacts on known and as yet unknown terrestrial and marine CHOs will be mitigated by archaeological watching briefs (monitoring), Chance Find Procedures and Cultural Heritage Awareness training. These measures will reduce any potential impacts to **Low** significance.

These measures will reduce any potential adverse impacts during the Construction and Pre-commissioning Phase to **Low** significance.

Operational impacts on terrestrial cultural heritage are not expected.

Operational impacts on unknown marine CHOs are largely mitigated through careful ROV piloting. These mitigation measures will reduce operational impacts to cultural heritage receptors to **Not Significant**.

Throughout the Project life-cycle, impacts on cultural heritage will be systematically controlled and monitored by the application of a Cultural Heritage CMP and OMPs both of which will include Chance Find Procedures and provisions for Cultural Heritage Awareness Training.

17 Ecosystem Services

17.1 Introduction

International Finance Corporation (IFC) Performance Standard (PS) 6 defines ecosystem services as “the benefits that people, including businesses, obtain from ecosystems” (Ref. 17.10), which accords with the definition provided by the Millennium Ecosystem Assessment (MA) (Ref. 17.1). While there is no single system for categorising ecosystem services, the MA framework is widely accepted and, as acknowledged in IFC PS Guidance Note 6 (paragraph 2), provides a useful starting point. The MA identifies four broad categories of ecosystem service:

- **Provisioning services** – the products people obtain from ecosystems. These may include *inter alia* (i) crops, livestock, seafood and game, wild foods, and ethnobotanical plants; (ii) water for drinking, irrigation, and industrial purposes; and (iii) vegetated areas which provide the basis for many biopharmaceuticals, construction materials, and biomass for renewable energy. Goods may be provided by heavily managed ecosystems, such as agricultural and aquacultural systems and plantation forests, or by natural or semi-natural ones, for example in the form of capture fisheries and the harvest of other wild foods;

- **Regulating services** – the benefits people obtain from the regulation of ecosystem processes. These may include *inter alia* (i) local climate regulation and carbon storage and sequestration; (ii) natural hazard mitigation; (iii) purification of water and air; (iv) control of pests and disease; and (v) pollination;

- **Cultural services** – the cultural, educational, and spiritual benefits people obtain from ecosystems. These may include *inter alia* (i) cultural, spiritual, or religious upliftment from cultural heritage, spiritual, or sacred sites; (ii) opportunities for recreation such as sport, hunting, fishing, ecotourism; and (iii) opportunities for scientific exploration, knowledge-building, and education; and

- **Supporting services** – the natural processes that maintain the other services such as soil formation, nutrient and water cycling, or primary production.

Supporting services differ from provisioning, regulating, and cultural services in that, unlike the other types of service from which people can directly benefit, their impacts on human well-being are indirect (Ref. 17.2 and Ref. 17.3) and mostly long-term in nature; the formation of soils, for example, takes place over decades or centuries. All other ecosystem services – regulating, provisioning, and cultural – ultimately depend on them. Supporting services are strongly interrelated to each other and are generally underpinned by a vast array of physical, chemical, and biological interactions. Supporting services are linked to particular biophysical structures or processes of an ecosystem, such as the way water storage is linked to soils, trees, plants, and other vegetation, and underpin the provision of the services which are of direct value to people, such as reduced surface water runoff, filtering of air and water quality, timber provision, and wild foods. These final ecosystem services provide benefits to people such as reduced damages from flooding, which are valued by their beneficiaries (Table 17.1).
The benefits of ecosystems are conferred at many scales and often to multiple different beneficiaries. At the local level, ecosystem services are frequently the basis for rural livelihoods and subsistence, particularly for the poor. Artisanal fishing of coastal waters and rivers, for example, provides both cash income and food for low-income families. Similarly, harvesting of plants for traditional medicine can provide an important substitute for more expensive commercially available pharmaceuticals. Benefits can also be regional – such as the provision of flood protection and erosion control afforded to communities and businesses by coastal mangroves – or national, such as sites that form part of a country's cultural heritage. At a global scale, ecosystems regulate climate and support the biodiversity which underpins all biological production.

Businesses and projects may also benefit from ecosystem services through, for example, the direct use of inputs such as water or through protection from natural hazards such as flooding. Identifying and protecting such services can have further benefits such as avoiding punitive regulation and negative publicity, strengthening the organisation's reputation and, in some cases, providing effective natural alternatives to more expensive engineering solutions.

Despite the widespread benefits of ecosystem services, a number of recent high-profile reports have revealed that a significant number of global ecosystems are in a degraded state. In 2005 for example, the MA concluded that on a global scale the majority of ecosystem services have been degraded (Ref. 17.1). More recently, The Economics of Ecosystems and Biodiversity (TEEB), a major international initiative, published a series of reports which found that many ecosystem services are so degraded they are reaching tipping points, and highlighted the growing costs of biodiversity loss and ecosystem degradation (Ref. 17.5).

This has led to a growing shift in national and international policy, away from looking at the environment in separate “silos” – air, water, soil, biodiversity – towards a more integrated approach based on entire ecosystems. Identifying impacts in this manner stresses the linkages and trade-offs between different services, allowing the ecosystem approach to identify areas which provide multiple benefits. Further, the emphasis placed on looking at the environment in terms of the benefits that people derive from it helps to ensure that the full value of ecosystem services and people's preferences for these are incorporated into decision-making processes.

In 2010, the Conference of the Parties to the Convention on Biological Diversity (CBD) adopted a Strategic Plan with the aim of "maintaining ecosystem services, sustaining a healthy planet, and delivering benefits essential for all people" (Ref. 17.6). The EU also adopted a target to halt...
the loss of biodiversity and the degradation of ecosystem services by 2020 and restore them where possible (Ref. 17.7).

In 2012, the vision for a Green Economy outlined in Rio +20 recognised that economic performance depends on effective ecosystem and biodiversity management and the continued flow of ecosystem services (Ref. 17.8). In the same year, the IFC published its revised Performance Standards on Environmental and Social Sustainability which, in addition to the requirements set out in PS 6, included reference to ecosystem services throughout many of the other Performance Standards (Table 17.1). More recently, the European Commission has put forward a proposal to amend the European EIA Directive to specifically include consideration of ecosystem services (Ref. 17.9).

IFC PS 6 recognises that sustainable development cannot be achieved if either biodiversity or ecosystem services are lost or degraded by development efforts and therefore requires that "where a project is likely to adversely impact ecosystem services, as determined by the risks and impacts identification process, the client will conduct a systematic review to identify priority ecosystem services" (Ref. 17.10). Since ecosystem services are, by nature, cross-cutting they apply to several of the IFC Performance Standards as shown in Table 17.1 below.

**Table 17.1 Ecosystem Services in the 2012 IFC Performance Standards**

<table>
<thead>
<tr>
<th>Performance Standard</th>
<th>Summary of Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS1: Assessment and Management of Environmental and Social Risks and Impacts</td>
<td>Where the project involves specifically identified physical elements, aspects, and facilities that are likely to generate impacts, environmental and social risks and impacts will be identified in the context of the project's area of influence. This area of influence encompasses, as appropriate...indirect project impacts on biodiversity or on ecosystem services upon which Affected Communities’ livelihoods are dependent.</td>
</tr>
<tr>
<td>PS4: Community Health, Safety, and Security</td>
<td>The project’s direct impacts on priority ecosystem services may result in adverse health and safety risks and impacts to Affected Communities. With respect to this Performance Standard, ecosystem services are limited to provisioning and regulating services as defined in paragraph 2 of Performance Standard 6...where appropriate and feasible, the client will identify those risks and potential impacts on priority ecosystem services that may be exacerbated by climate change. Adverse impacts should be avoided, and if these impacts are unavoidable, the client will implement mitigation measures in accordance with paragraphs 24 and 25 of Performance Standard 6. With respect to the use of and loss of access to provisioning services, clients will implement mitigation measures in accordance with paragraphs 25–29 of Performance Standard 5.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Performance Standard</th>
<th>Summary of Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>PS5: Land Acquisition and Involuntary Resettlement</td>
<td>This Performance Standard applies to physical and/or economic displacement resulting from the following types of land-related transactions...restriction on access to land or use of other resources including communal property and natural resources such as marine and aquatic resources, timber and non-timber forest products, freshwater, medicinal plants, hunting and gathering grounds and grazing and cropping areas (natural resource assets referred to in this Performance Standard are equivalent to ecosystem provisioning services as described in Performance Standard 6).</td>
</tr>
<tr>
<td>PS6: Biodiversity Conservation and Sustainable Management of Living Natural Resources</td>
<td>Where a project is likely to adversely impact ecosystem services, as determined by the risks and impacts identification process, the client will conduct a systematic review to identify priority ecosystem services...with respect to impacts on priority ecosystem services of relevance to Affected Communities and where the client has direct management control or significant influence over such ecosystem services, adverse impacts should be avoided. If these impacts are unavoidable, the client will minimise them and implement mitigation measures that aim to maintain the value and functionality of priority services. With respect to impacts on priority ecosystem services on which the project depends, clients should minimise impacts on ecosystem services and implement measures that increase resource efficiency of their operations, as described in Performance Standard 3. Additional provisions for ecosystem services are included in Performance Standards 4, 5, 7, and 8.</td>
</tr>
<tr>
<td>PS7: Indigenous Peoples</td>
<td>If the client proposes to locate a project on, or commercially develop natural resources on lands traditionally owned by, or under the customary use of, Indigenous Peoples, and adverse impacts can be expected, the client will take the following steps...document efforts to avoid and otherwise minimise impacts on natural resources and natural areas of importance to Indigenous People. &quot;Natural resources and natural areas of importance&quot; as referred to in this Performance Standard are equivalent to priority ecosystem services as defined in Performance Standard 6...where a project may significantly impact on critical cultural heritage that is essential to the identity and/or cultural, ceremonial, or spiritual aspects of Indigenous Peoples lives, priority will be given to the avoidance of such impacts (natural areas with cultural value are equivalent to priority ecosystem cultural services as defined in Performance Standard 6). Where significant project impacts on critical cultural heritage are unavoidable, the client will obtain the Free, Prior and Informed Consent (FPIC) of the Affected Communities of Indigenous Peoples. Includes natural areas with cultural and/or spiritual value such as sacred groves, sacred bodies of water and waterways, sacred trees, and sacred rocks.</td>

Performance Standard | Summary of Requirements
--- | ---
PS8: Cultural Heritage | Where the client has encountered tangible cultural heritage that is replicable and not critical, the client will apply mitigation measures that favour avoidance. Where avoidance is not feasible, the client will apply a mitigation hierarchy as follows...minimise adverse impacts and implement restoration measures, in situ, that ensure maintenance of the value and functionality of the cultural heritage, including maintaining or restoring any ecosystem processes needed to support it (consistent with requirements in Performance Standard 6 related to ecosystem services and conservation of biodiversity).

The assessment in this chapter has been undertaken in accordance with the 2012 IFC Performance Standards (Ref. 17.10), drawing on the Guidance Notes that accompany the Standards (Ref. 17.11). The approach is also informed by separate on-going dialogue between URS and the IFC's Environment, Social, and Governance Department (Ref. 17.12) and the World Resources Institute (WRI) (Ref. 17.13) regarding their risk screening procedures, expectations of ecosystem services assessments, and emerging guidance on consideration of ecosystem services in ESIA.

This chapter presents an assessment of the potential impacts and dependencies on ecosystem services resulting from the Construction and Pre-Commissioning, Operational, and Decommissioning Phases of the Project. In addition, measures to anticipate and avoid, or where avoidance is not possible, minimize, and, where residual impacts remain, compensate / offset for risks and impacts on priority ecosystem services are presented.

Specifically, the purpose of this chapter is to:

- Systematically identify and assess the likely impacts of Project activities on ecosystem services (ESS) and the nature and significance of these impacts on ESS beneficiaries;
- Evaluate Project dependence on ESS in order to help manage risks and take advantage of opportunities related to ecosystem change; and
- Help inform, for unavoidable impacts, the selection of appropriate mitigation measures which aim to maintain the value and functionality of priority ESS and enhance the resource efficiency of Project operations.

This chapter is not intended to be read in isolation; instead it presents and assesses the key ecosystem service considerations relevant to the topics presented in other chapters of this ESIA Report, including key inter-linkages, to ensure that the values which ecosystem service

---

1 The ESS framework focuses on assessing impacts on the beneficiaries of ecosystem services. Where impacts on ecosystem services reduce the benefits to beneficiaries, then these beneficiaries are identified as Project Affected Communities (PACs). Thus, not all ESS beneficiaries will necessarily be PACs. A beneficiary only becomes a PAC when the Project reduces the level of benefits provided to an individual or group of beneficiaries.
beneficiaries attach to ecosystem goods and services are appropriately considered and addressed throughout the ESIA process.

The findings of the assessment in this chapter have also been used to inform the baseline data collection process, impact assessment, and selection of appropriate mitigation options in other relevant technical chapters. This chapter brings together the findings of the other chapters to examine the issues at an ecosystem level and to assess how impacts on one aspect of the environment can affect others. As such, the chapter is heavily informed by the other chapters of the ESIA Report and cross references these where appropriate.

There are, therefore, significant overlaps between the assessment presented in this chapter and in the other technical chapters. For example, impacts on fisheries, crops, and tourism and recreation are all covered in both this chapter and in Chapter 14 Socio-Economics. While the assessment of these issues is broadly similar across the two chapters and each assessment has informed the other, it is important to note that this chapter uses an ecosystem services assessment framework to assess impact significance and, as such, there may be differences between the receptor sensitivities and impact magnitudes across chapters. This is due to the fact that the ecosystem services assessment considers the impact of the Project on ecosystem functioning and ability to continue providing services, as well as the ability of all those who access or benefit from those services to continue to derive services of the same value.

17.2 Approach

The approach to, and methodology for, the ecosystem services assessment in this chapter is based the Ecosystem Services Identification, Valuation, and Integration (ESIVI) approach (Ref. 17.14). The ESIVI tool was created in order to provide a rigorous and transparent framework for ecosystem service assessments that meets the requirements set out in the 2012 IFC Performance Standards.

The development of the ESIVI tool was informed by both the conceptual framework established by the MA, which explicitly links ecosystem services and human well-being, and the WRI's conceptual framework for Ecosystem Services Review for Impact Assessment (Ref. 17.15). The WRI framework puts the Project at the centre of the interactions between human well-being, ecosystem services, ecosystems, and drivers of ecosystem change, recognising that the Project has the potential to affect all the components of the framework and is itself affected by them. It reflects the two ways the Project relates to ecosystem services in terms of:

- Potential impacts on the existing relationships between human well-being, ecosystem services, and ecosystems; and
- Project dependence on these relationships for the achievement of successful performance.

The development of the ESIVI tool was informed by expertise built up from carrying out policy and project level work on ecosystem service assessments over the past ten years as well as a number of Good International Industry Practices and guidelines, including:

- IFC Performance Standards 1, 4, 5, 6, 7, and 8 and their accompanying Guidance Notes (Ref. 17.11);
The ecosystem services assessment process comprises four stages:

- **Scoping** – to identify the services provided by affected ecosystems that could potentially be impacted by the Project or that the Project may depend upon;
- **Baseline establishment** – to assess the status of these services within the affected ecosystems in the absence of the Project, as well as the location of ecosystem service beneficiaries and the extent to which they benefit from the services provided;
- **Impact assessment** – to identify the likely impacts of Project activities on ecosystem services and their beneficiaries, the significance of these impacts, and which services should be considered priority ecosystem services; and
- **Mitigation and residual impact assessment** – to identify the range of measures that may be implemented to anticipate and avoid, or where avoidance is not possible, minimize adverse impacts on priority ecosystem services and to determine the residual impacts once mitigation is in place.

Figure 17.2 provides a schematic overview of the assessment process and the key sources of data at each stage.

---

2 Note that these stages of the ESIVI tool are consistent with the impact assessment methodology described in Chapter 3 Impact Assessment Methodology and used in other chapters.
17.3 Scoping

The objective of the initial scoping exercise is to identify those ecosystem services which could potentially be affected by Project activities or that the Project may depend upon and which therefore ought to be subject to more detailed investigation.

Due to the complexity and interconnectivity of ecosystems, together with the uncertainty surrounding how each process within an ecosystem is likely to respond to change, isolating and assessing each of the likely impacts of a project on particular ecosystem services is a difficult task. Further, the potentially wide range of people who benefit from ecosystem services and the different values they attach to such services mean that assessing the impacts and dependencies of a project on ecosystem services is an extensive undertaking.
As such, a comprehensive assessment of every impact or dependency on each ecosystem service and an economic valuation of each type of use is beyond the scope of an ESIA. An effective ESIA should therefore focus resources on assessing the services which are likely to be of highest priority, with further, more detailed assessments being carried out where necessary to inform the development of follow up reports. For example, while it is not appropriate to undertake a full economic valuation for each ecosystem service within an ESIA, valuing certain services may be a useful exercise for informing the development of Livelihood Restoration Plans which depend on ecosystem based forms of income such as fishing and farming.

An important element of the scoping stage is therefore to identify which services can be excluded from the ESIA in order to provide a comprehensive and manageable assessment. This was done using the ESIVI tool which contains a checklist of ecosystem services that has been compiled using the guidance, checklists, and other relevant information contained in the studies listed in the previous section.

In this assessment the ESIVI checklist (Table 17.2) was used to systematically identify the services which may potentially be impacted by the Project or upon which the Project may depend. Definitions and examples of each of the ecosystem services are provided in Appendix 17.1 Ecosystem Services Checklist.

3 Note, IFC Guidance Note 6 states that "client requirements are focused on the mitigation of impacts on ecosystem services and the benefits that ecosystem services might bring to companies rather than on the economic valuation for such services".
Chapter 17 Ecosystem Services

Provisioning Services

| Fibres and ornamental resources |

Regulating Services

| Genetic resources |

Cultural Services

Complete.

It is important to note that impacts on supporting services are not explicitly accounted for in the ESIVI ecosystem services assessment in order to avoid double-counting. This follows from Bateman et al. who draw the distinction between supporting ecosystem services (e.g. nutrient cycling), final ecosystem services (e.g. growth of trees), goods (e.g. timber), and benefits (e.g. livelihoods) (Ref. 17.2).

Final ecosystem services are the last item in the chain of ecosystem functioning which inputs to the production of goods. They are the aspects of the natural environment which most directly affect human well-being. This focus on the final item in the chain of ecosystem services is to avoid the double counting which would occur if an attempt is made to value those intermediate ecological processes or outcomes (e.g. weathering, photosynthesis, nutrient cycling, etc.) which are captured elsewhere in the provisioning, regulating, and cultural services that they support. For example, the impacts of supporting services such as photosynthesis are accounted for in terms of their support of crop growth and timber production.

An important exception is nevertheless made in the case of biodiversity. The authors of the MA argued that biodiversity underpins ecosystem function and should therefore be categorised as a supporting service. As such, biodiversity in itself would be excluded from the ecosystem service assessment in order to avoid double-counting. However, a number of other studies suggest that the existence of biodiversity is itself a service, regardless of whether or not it provides a supporting role in the provision of any other services, and that people are willing to pay to preserve global biodiversity even if they do not benefit from any of the ecosystem services it supports (Ref. 17.20, 17.21 and 17.22). Excluding biodiversity from the ecosystem services assessment would fail to capture such values.

Therefore, in order to capture as wide a range of benefits as possible, and following the approach of the landmark UK National Ecosystem Assessment (Ref. 17.19), “wild species diversity” is included in the assessment as a distinct cultural service in its own right. To avoid double counting, the ecosystem services assessment distinguishes between biodiversity as a supporting function, and wild species diversity that is valued for its own sake (i.e. the existence value that people are willing to pay for the preservation of particular species, or local values attached to particular species which are not captured within other services). As a result, the assessment for wild species diversity focuses on any threats to populations of locally, regionally, nationally, or globally significant species.

Using the ESIVI checklist (Table 17.2), the range of ecosystem services potentially provided by the affected ecosystems, and the likely beneficiaries (direct or indirect) of each of those services were identified. As set out in PS 1, the emphasis during the initial identification stage is on covering the broadest possible scope of beneficiaries, including:
• Local beneficiaries, such as those who benefit from growing crops in a household plot close to where they live;
• Regional beneficiaries, such as those living within a watershed who benefit from flood protection;
• National beneficiaries, such as those across the country who visit an area for tourism / recreational purposes; and
• Global beneficiaries, such as those across the world who for example, benefit from carbon sequestration.

Identifying the type of beneficiary is important at this stage because different types of beneficiary are assessed differently with regards to mitigation requirements. For example, IFC PS 6 applies to ESS whose beneficiaries are at the local or regional scale, while PS 1 applies to ESS with global beneficiaries, such as carbon sequestration. Further, the type of beneficiaries also informs whether an ecosystem service is classed as a Type 1 service, where impacts on ecosystem services may adversely affect communities, or a Type 2 service, where the project directly depends on an ecosystem service for its operations. Identification of beneficiaries at this stage also informs the baseline data collection plan by identifying the particular groups or individuals who need to be consulted about the extent to which they presently benefit from (or value) each of the ecosystem services identified.

Once the broadest possible range of potential ecosystem services and their associated beneficiaries were identified, each service was systematically reviewed and scored against the inclusion criteria shown in Table 17.3 to identify which ecosystem services should be included in the more detailed impact assessment and which should be scoped out of the assessment.

<td>Benefit: Project is likely to have a positive impact on service provision. Does not have to be assessed further.</td>
</tr>
</tbody>
</table>

* Note, under the scoring system set out in Table 17.3, a service can only be classed as high relevance if it is both a Type 1 and a Type 2 service i.e. the Project could reduce the benefits that people derive from the service and the Project itself depends on the service for successful performance.

** Note, this criterion specifically refers to potential impacts on users of a service while the preceding criterion refers to potential impacts on the ecosystem which provides the service. This is an important distinction because a Project may have significant impacts on an ecosystem (such as by withdrawing significant amounts of water from a river), however, whether or not people are using this service is an important factor in assessing the significance of the impact.

† Note, this criterion follows the guidelines set out in the IFC PS and identifies whether a client can be said to have control over a Project’s impacts on an ecosystem service (this may exclude, for example, upstream manufacture of inputs or downstream use of a product) and whether the impacts are likely to be of significant influence (while a Project may impact on a service, for example, it may be possible to exclude these impacts from the assessment if it is known at the scoping stage that the impacts will be insignificant in terms of beneficiaries well-being).
The purpose of this initial scoping exercise was to identify any ecosystem services that may be provided by affected ecosystems, the extent of use, and how likely each of these services are to be impacted by the Project. Once the likely relevance was assessed, a shortlist of ecosystem services to be included in the baseline and impact assessment sections was compiled. Since this is a scoping exercise, the potential impact ratings shown in Table 17.4 should not be interpreted as an ultimate determination of impact significance; rather they are intended as an indication of the potential for an impact on a service to occur and the potential level of that impact.

The scoping exercise was undertaken through a review of both the information and data collected for the Russian Sector EIA and other ESIA chapters, including satellite mapping, site visits, and stakeholder consultation. A review of published literature was also carried out to supplement the existing evidence and to provide more detailed technical information where needed. As further information became available throughout the baseline and impact assessment process, the initial scoping exercise was revisited and updated where necessary in order to ensure that all relevant ecosystem services were included in the impact assessment.

The scoping exercise resulted in the identification of ten ecosystem services to be taken forward for more detailed assessment. These are:

- Crops;
- Capture fisheries;
- Water (supply);
- Hazard regulation;
- Air quality regulation;
- Water quality regulation;
- Soil quality regulation;
- Tourism and recreation values;
- Cultural and spiritual values; and
- Wild species diversity.

The full results of the scoping exercise are found in Appendix 17.2 Scoping Results while a summary of the rationale for inclusion or exclusion of each ecosystem service is provided in the following table.
<table>
<thead>
<tr>
<th>Ecosystem Service</th>
<th>Relevance*</th>
<th>Include in Impact Assessment</th>
<th>Justification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Crops</td>
<td>Moderate</td>
<td>Yes</td>
<td>Construction of the Pipeline will require some temporary and permanent loss of agricultural land. Vineyards would be the primary crop affected. The loss of agricultural production could have an impact on the current and future income from productive land which could also impact on employment opportunities.</td>
</tr>
<tr>
<td>Livestock &amp; fodder</td>
<td>Negligible</td>
<td>No</td>
<td>There is no evidence of livestock farming or any grazing areas within the vicinity of the Project Area and it is unlikely that provision or use of the service will be affected by the Project.</td>
</tr>
<tr>
<td>Capture fisheries</td>
<td>Moderate</td>
<td>Yes</td>
<td>Fishing is undertaken along the coast in the vicinity of the marine component of the Project. At the time of scoping it was identified that the Project could limit access to fishing areas and could disturb fish habitats and fisheries productivity, which could impact livelihoods and well-being. Furthermore, several fishing organisations voiced concerns during the stakeholder consultation meetings held between 10th and 14th December 2012 and in October 2013 around the potential for the Project to restrict access to fishing grounds, to act as a barrier to fish migration, or to impact upon fisheries productivity as a result of noise and vibration (Chapter 6 Stakeholder Engagement).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Ecosystem Service</th>
<th>Relevance*</th>
<th>Include in Impact Assessment</th>
<th>Justification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aquaculture</td>
<td>Negligible</td>
<td>No</td>
<td>There is a mussel farm located around 3.8 km to the south of the proposed Pipeline route, near Bolshoi Utrish marina. However, the Project is not expected to impact upon mussel farming activities due to the distance from Project activities (Appendix 14.1 Fisheries Study).</td>
</tr>
<tr>
<td>Wild foods</td>
<td>Low</td>
<td>No</td>
<td>Hunting is prohibited in the area in which the Project is located, although information suggests that poaching of species such as rabbit, deer, wild boar, tortoise, and game birds may occur. Due to the limited amount of habitat that will be impacted by the Project relative to the surrounding area, the Project is unlikely to significantly impact the numbers or distributions of such species. Rural households may also collect wild foods from forested areas within the vicinity of the Project Area and the Project could reduce the provision of such foods due to vegetation clearance and through restricting access to land within the Project Area. Conversely, however, vegetation clearance could increase accessibility to this resource by providing a path which could be used to exploit forest resources that are not directly affected by Project activities. Overall, the scale of vegetation loss is minor and the habitat is well replicated nearby. As such, any impact on provision or use of the service is likely to be low.</td>
</tr>
<tr>
<td>Timber</td>
<td>Negligible</td>
<td>No</td>
<td>The Project Area covers an area of forest owned by the State Forestry Department. However, there is no timber harvesting or woodland management regime in place within this area of forest so there is unlikely to be any impact on timber provision. At the time of scoping it was identified that rural households may collect timber from other forested areas surrounding the Project Area however these areas would not be impacted by the Project. The Project could have a temporary beneficial impact on this service if the timber cleared during construction is made available for rural households.</td>
</tr>
</tbody>
</table>

Continued...
<table>
<thead>
<tr>
<th>Ecosystem Service</th>
<th>Relevance*</th>
<th>Include in Impact Assessment</th>
<th>Justification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Energy</td>
<td>Low</td>
<td>No</td>
<td>Forested ecosystems within the vicinity of the Project Area provide a supply of wood that could be harvested as an energy resource. At the time of scoping it was identified that rural households may collect wood from forested areas potentially impacted by the Project and that the Project has the potential to reduce the availability of such fuels due to vegetation clearance. However, the scale of vegetation loss is relatively minor and habitat is well replicated nearby. Further, vegetation clearance may increase accessibility to this resource by providing a path which could be used to exploit forest resources that are not directly affected by Project activities. As such, any impact on provision or use of the service is considered to be low. As with timber provision, the Project could have a temporary beneficial impact on this service if the vegetation cleared during construction is made available for rural households. There is no use of other ecosystem-based energy such as biofuels or hydropower that could be affected by the Project.</td>
</tr>
<tr>
<td>Biochemicals / medicine</td>
<td>Low</td>
<td>No</td>
<td>Consultation with the local administration and government agencies revealed that there may be some collection of flora and fauna within the vicinity of the Project Area which is believed to have medicinal and/or spiritual properties. Local households (particularly elderly members) may also harvest herbs and plants growing in and around the Project Area to produce family cures and teas. These species have been extensively catalogued (Ref. 17, 23). The Project could potentially reduce the provision of such resources due to vegetation clearance and habitat loss. However, the scale of vegetation loss is relatively minor and habitat is well replicated nearby. The construction of access roads and clearance of forest could also increase the accessibility of such resources. As such, any impact on provision or use of the service is considered to be low.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Ecosystem Service</th>
<th>Relevance*</th>
<th>Include in Impact Assessment</th>
<th>Justification</th>
</tr>
</thead>
<tbody>
<tr>
<td>Water (supply)</td>
<td>Moderate</td>
<td>Yes</td>
<td>At the time of scoping it was identified that there are several surface and ground water resources present within the Project Area which flow to and/or are used directly by beneficiaries for drinking and industrial / agricultural uses. The Project Area crosses water courses at several points and could impact downstream surface water flows. The clearance of vegetation could also impact surface flows and groundwater recharge rates. Changes in the availability of water resources could impact the well-being of potential beneficiaries. Freshwater is required for Project activities and so this is identified as a Type 1 and a Type 2 service. Water required by the Project will be abstracted from a Ministry of Defence owned well near Sukko and tankered in to the site. The abstraction of water could draw down water levels and impact the ability of other users to access water.</td>
</tr>
<tr>
<td>Fibres and ornamental resources</td>
<td>Low</td>
<td>No</td>
<td>Shells are collected from the marine environment, which are sold as handicrafts in local markets (particularly a certain species of conch with a large orange shell). The Project could temporarily (during construction) impact access to areas where shells are collected although this is likely to have minimal impact on service use and provision as shells may be collected from other sites along the coast and the supply of shells is unlikely to be significantly impacted.</td>
</tr>
<tr>
<td>Genetic resources</td>
<td>Negligible</td>
<td>No</td>
<td>There is no evidence of any use of flora or fauna within or immediately surrounding the Project Area for the conservation or preservation of genetic resources. While it is possible that there may be as yet undiscovered genetic resources, there is no recorded scientific interest in the immediate vicinity of the Project Area and the habitat and fauna is replicated nearby, particularly in the Utrish State Nature Reserve, which is likely to provide a more important source of genetic resources.</td>
</tr>
<tr>
<td>Local climate regulation</td>
<td>Negligible</td>
<td>No</td>
<td>Due to the small scale of the Project Area relative to the extent of the surrounding ecosystems, it is unlikely that the area impacted by the Project plays an important role in local climate control, e.g. the regulation of precipitation, cooling, or shading etc. As such there is unlikely to be any significant change in provision or use of this service.</td>
</tr>
<tr>
<td>Ecosystem Service</td>
<td>Relevance*</td>
<td>Include in Impact Assessment</td>
<td>Justification</td>

<tr>
<td>-------------------</td>
<td>------------</td>
<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Global climate regulation</td>
<td>Low</td>
<td>No</td>
<td>Vegetation and soils play a role in sequestering and storing greenhouse gases. Construction of landfall facilities and the Pipeline, clearance of vegetation, and fuel burnt in generators and transportation will generate greenhouse gases. Disturbance of the seabed could also potentially lead to the release of methane deposits. However, the impact of these activities relative to global greenhouse gas emissions and their effects on the well-being of populations affected by climate change is considered to be negligible (Chapter 9 Air Quality).</td>
</tr>
<tr>
<td>Hazard regulation</td>
<td>Moderate</td>
<td>Yes</td>
<td>Both the Project and local communities depend on the capacity of natural systems to regulate natural hazards such as floods, mudslides, and erosion. Several stakeholders from Varvarovka and Gai Kodzor raised the potential for increased flood risk as an issue during the initial stakeholder engagement exercise held in December 2012 (Chapter 6 Stakeholder Engagement). The Project could potentially impact local flooding events through the crossing of water courses. The clearance of vegetation (which binds soil particles) could also lead to an increase in erosion. Marine dredging could affect natural coastal processes leading to changes in coastal erosion and flooding. Since both local communities and the Project itself depend on hazard regulation, this is both a Type 1 and a Type 2 service.</td>
</tr>
<tr>
<td>Air quality regulation</td>
<td>Moderate</td>
<td>Yes</td>
<td>Air quality regulation is an important service within Anapa Resort Town which is renowned and marketed for its health benefits (Ref. 17.24). At the time of the scoping exercise it was identified that the Project could impact air quality regulation through the clearance of vegetation which plays a role in absorbing pollutants from the atmosphere (Ref. 17.25) as well as through emissions from construction vehicles and equipment.</td>
</tr>
<tr>
<td>Ecosystem Service</td>
<td>Relevance*</td>
<td>Include in Impact Assessment</td>
<td>Justification</td>

<td>------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Water quality regulation</td>
<td>Moderate</td>
<td>Yes</td>
<td>Good water quality is important for fishing, human consumption, tourism, as well as for general ecosystem functioning. The Project could impact marine, surface, and ground water resources through spills, leaks, disposal of wastewater etc. during construction. Any Project contamination of groundwater is likely to be an important issue where people are abstracting directly from groundwater resources. Dredging (which could potentially expose contaminants in the sea bed) and disposal of hydrotest water could impact marine water quality with potentially significant impacts on well-being for the tourism industry, recreational water users, and fishing.</td>
</tr>
<tr>
<td>Pollination</td>
<td>Low</td>
<td>No</td>
<td>Several Lepidoptera (in their butterfly or moth adult life stage) and bee species feed on flower nectar and play a role in pollination within the ecosystems surrounding the Project Area. The primary habitat types which support such species are secondary and mesophilic meadows. The terrestrial land take required by the Project is likely to lead to a small loss of secondary meadow. The limited extent of this loss in respect to the surrounding habitat means that the Project is unlikely to significantly impact the distribution or population of any important natural pollinators. As such, the impact on the provision and use of the service is expected to be low.</td>
</tr>
<tr>
<td>Disease and pest control</td>
<td>Negligible</td>
<td>No</td>
<td>There is no evidence to suggest that the ecosystems or any particular species within the vicinity of the Project Area play a significant role in pest control. There is also no evidence of any habitats (e.g. standing water) which may influence the incidence and abundance of human pathogens (Chapter 15 Community Health, Safety and Security).</td>
</tr>
<tr>
<td>Noise regulation</td>
<td>Negligible</td>
<td>No</td>
<td>There is no evidence that ecosystems within the vicinity of the Project Area play an important role in noise regulation.</td>

</tr>
<tr>
<td>Soil quality regulation</td>
<td>Moderate</td>
<td>Yes</td>
<td>Terrestrial soil quality is important for landowners, workers, human health, flora, and fauna. Healthy soil also plays an important role in flood regulation through the capacity for water absorption. The Project could impact this service through excavation of top soil, clearance of vegetation, and contamination through leaks and spills. The potential Project impact on soils was raised by several Supsekh residents during the initial stakeholder engagement exercise.</td>
</tr>
<tr>
<td>Tourism &amp; recreation values</td>
<td>Moderate</td>
<td>Yes</td>
<td>Tourism is an important and growing industry in the region and potential Project impacts on this service were raised during the initial stakeholder engagement exercise. The Project could affect both terrestrial and marine tourism and recreation (e.g. through temporary loss of access or disturbance to hiking trails, beaches, and the marine environment). In particular, the well-being of the owners of, and visitors to, the Shingari and Don resort complexes could be impacted by the Project due to restricted access to areas used for water sports, by visual and noise disturbance during the construction period, or by potential impacts on marine water quality. Potential impacts on Sukko beach were raised during stakeholder consultation (<a href="#">Chapter 6 Stakeholder Engagement</a>).</td>
</tr>
<tr>
<td>Cultural &amp; spiritual values</td>
<td>Moderate</td>
<td>Yes</td>
<td>The natural environment plays an important role in the cultural identity and aesthetic value of the area (including Anapa, Gai-Kodzor, Sukko, Supsekh and Varvarovka). There are also a number of sites of cultural (graves / cemeteries / war memorials), scientific (archaeological remains), and spiritual (churches / sacred springs / religious and community festivals) importance. The Project could temporarily disturb such sites and permanently change elements of the natural environmental setting of the area which could impact on the well-being of any beneficiaries.</td>

<td>Benefit</td>
<td>No</td>
<td>Marine surveys for the Project collected geophysical data from Black Sea locations not previously studied. Preliminary analysis of this data suggests that the Project has facilitated the discovery of information which will be valuable to scientific knowledge. Publication of the results of this research will be explored in appropriate academic publications when available. Bacterial life which has adapted to survive in extreme anoxic environments may be present in areas of deep water offshore. While some mussel / bacterial matts were identified there was no evidence to suggest that this life is of any unique interest to science. Due to the potentially significant contribution to science that such surveys have revealed, the impact of the Project on this service is considered to be beneficial.</td>
</tr>
<tr>
<td>Wild species diversity</td>
<td>Moderate</td>
<td>Yes</td>
<td>A number of terrestrial and marine species of national and global conservation importance are present in the ecosystems within and surrounding the Project Area, including critically endangered sturgeon species and a critically endangered tortoise species. The Project could impact such species through collisions, disturbance, severance, loss of habitat etc. Further, the most common concern raised by stakeholders during consultation (raised 33 times) was the Project’s potentially negative impact on the natural environment, including the marine environment, the coastline, onshore valuable habitat area (e.g. the mountain area of the Kilberov Canyon), juniper trees, and local wildlife around the proposed compressor station (Chapter 6 Stakeholder Engagement). As such, impacts on wild species may potentially have a direct impact on the well-being of stakeholders including local communities and NGOs.</td>
</tr>

</table>

*As calculated using the approach set out in Table 17.3, see Appendix 17.2 for full details.
17.4 Spatial and Temporal Boundaries

Ecosystem services are the contributions that ecosystems make to human well-being and business performance. As such, the focus of the ecosystem services assessment is on assessing changes in beneficiary well-being (including both Affected Communities and the Project itself), as a result of impacts on ecosystems and their associated services (Figure 17.3).

The assessment in this chapter therefore differs from other chapters in that it involves a two-stage process. First, the impacts on the ecosystem and its associated services (the physical receptor) need to be understood before the implications for ecosystem service beneficiaries (the social receptor) can be assessed.

As such, the spatial boundaries of this assessment are determined by: the Project Area and the ecosystems within it which are affected by the construction, operation, and decommissioning phases of the Project (a physically defined area); the flows of ecosystem services generated by these ecosystems; and ultimately, the locations of the ecosystem service beneficiaries (a socially defined area).

The relationship between the Project Area, the Affected Ecosystems, and the Affected Beneficiaries is illustrated in Figure 17.4 below. Further details on each of the assessment areas are provided in the following sections.
17.4.1 Project Area

The Project Area includes landfall, nearshore, and offshore sections. These are described in detail in Chapter 1 Introduction and in Chapter 5 Project Description.

17.4.2 Affected Ecosystems

The Affected Ecosystems are defined by the extent of the ecosystems or land uses which are most likely to be impacted by the construction, operation, or decommissioning phases of the Project.

Since ecosystems make up interconnected areas of natural habitat they cannot be restricted to a particular spatial area on a map. However, drawing a defined spatial boundary at this stage provides a basis for identifying the ecosystems most likely to be impacted by the Project. Since the Project includes both onshore and offshore components, the potential impacts on both marine and terrestrial ecosystems (including inland freshwater bodies) are considered.

17.4.2.1 Terrestrial Affected Ecosystems

Any ecosystems which fall at least partly within the landfall section of the Project Area could potentially be impacted by the Project through habitat loss, vegetation clearance, compaction, etc., while certain activities such as leaks, spills or emissions could have physical impacts on ecosystems (or parts thereof) outside of the Project Area.

Further, while the area within the safety exclusion zone (a 410 m width surrounding the Pipeline and the landfall facilities) may not experience any direct physical impacts, there will be restrictions on land use and development within the exclusion zone which could potentially affect access to ecosystem services provided in situ (e.g. crops, wild foods, etc.).

For the purposes of the ecosystem services assessment, the starting point for identifying potentially Affected Ecosystems has been defined as a 1 km radius surrounding the landfall section, extending to the coastline (Figure 17.5).⁴

---

⁴ Note, taking this as a starting point recognises that the extent of the Affected Ecosystem could extend beyond the 1 km boundary. These wider impacts are accounted for through the assessment of impacts on beneficiaries.

17.4.2.2 Marine Affected Ecosystems

As noted above, the Project Area is divided into landfall, nearshore and offshore sections. This division is based on technical consideration of different construction activities to be employed in each section, and has no connection to the ecosystems in which Project activities take place. For the purposes of assessing the impacts on marine ecosystem services, and following the approach taken in Chapter 12 Marine Ecology, the ‘nearshore section’ is therefore considered to also include the area between 0 to 23 m water depth, which forms part of the ‘landfall section’ in the Project Description. Because the nearshore and offshore sections of the Project Area are ecologically contiguous, they are considered as one in this chapter.

During the construction phase of the Project the nearshore section of the Project Area is defined by the maritime safety exclusion zones around the construction vessels, extending out 3 km either side of the outermost pipeline, encompassing:

- The area impacted by sediment dispersion, based on sediment models;
- The route of the four individual pipelines;
- The likely anchor spread and movement locations of vessels directly associated with the Pipeline installation and maintenance; and
- The proposed microtunnel exit pit and temporary dredge storage location.

The nearshore section Project Area is approximately 5.2 km².

The offshore section is approximately 225 km in length and pipelines will be laid directly on the sea bed from the maximum water depth where dredging works will take place (30 m water depth), to the boundary between the Russian and Turkish EEZs. The Project Area of the offshore section consists of a corridor of 3 km from the boundary of the nearshore section to the 600 m water depth contour, after which the corridor decreases to 2 km width either side of the outermost pipeline from the 600 m water depth contour to the EEZ boundary. The offshore section of the Project Area encompasses:

- The area impacted by sediment dispersion, based on sediment models;
- The route of the four individual pipelines; and
- The likely anchor spread and movement locations of vessels directly associated with the Pipeline installation and maintenance.

The offshore section is approximately 1,080 km² which is 206 km² from the nearshore boundary to the 600 m water depth contour and 874 km² from this to the EEZ boundary.

During the operation phase the Project Area will be smaller, defined by the operation exclusion zone of 0.5 km either side of the outside pipelines from the microtunnel exit point to the Russian / Turkish EEZ boundary (end of offshore section).

The starting point for assessing the potential impacts on ecosystem services in the marine environment has been delineated as a 3 km wide corridor following the nearshore section of the Pipeline to the 600 m water depth contour, and then a 2 km wide corridor from the 600 m water depth contour to the EEZ boundary. Again, taking this as a starting point recognises that
the potential extent of predicted impacts (e.g. noise disturbance) may extend beyond this boundary. These are captured in the assessment of impacts on beneficiaries.

17.4.3 Affected Beneficiaries

Due to the interconnectedness of ecosystem processes and the flows of services they provide, impacts on Affected Ecosystems may also influence the ability of people to use or access particular services outside of the Affected Ecosystems.

For example, abstraction from surface waters within Affected Ecosystems, could reduce surface water flows which could impact the ability of beneficiaries to abstract water downstream. Likewise, fish species may breed at particular sites within marine Affected Ecosystems and then migrate throughout the marine environment supporting fishing industries across multiple countries.

As such, beneficiaries living outside of the Affected Ecosystems may be impacted by changes to the services provided and the assessment therefore needs to consider, "project-related impacts across the potentially affected landscape or seascape...which does not necessarily correspond to any one pre-defined unit of geographical space" (Ref. 17.26).

Further, the location of beneficiaries can vary depending on the type of service and, as such, beneficiaries are not restricted to a particular spatial area or landscape. For example, while the beneficiaries of the local climate regulation service may be restricted to the surrounding area, the beneficiaries of global climate regulation may be located throughout the world. As such, the extent of impacts on beneficiaries of ecosystem services can extend far beyond the Project Area or the Affected Ecosystems.

The Affected Beneficiaries are therefore defined by the location of the beneficiaries of the services provided by or dependent upon the Affected Ecosystems. While most of the beneficiaries are likely to be located within or around the ecosystems providing services, they vary across different services and can be located regionally, nationally, or even globally.

As such, the locations of Affected Beneficiaries are not restricted to a single pre-defined unit of geographical space and instead are defined for each ecosystem service depending on the beneficiaries of that service.

While the focus of the assessment in this chapter is on potential impacts on local beneficiaries living close to or within the Affected Ecosystems (defined as beneficiaries living in the Local Area\(^5\)), impacts on regional, national, and global beneficiaries are identified and accounted for where applicable (Table 17.5 and Figure 17.7).

---

\(^5\) Note: the definition of the Local Area is in alignment with the Local Communities identified in Chapter 14 Socio-Economics and encompasses the towns of Anapa, Gai-Kodzor, Sukko, Supsekh, Rassvet, and Varvarovka. Defining a Local Area in this manner is used to delineate between local and regional beneficiaries in order to provide a focus for the assessment. While beneficiaries living within the Local Area provide the main focus of the assessment, impacts on regional, national, global beneficiaries are identified where relevant and included in the assessment.

17.4.4 Temporal Boundaries

The temporal boundaries of this assessment are defined by the five key phases of the Project as set out in Chapter 1 Introduction. These include:

- Feasibility Phase (2007 to 2011);
- Development (or Design) Phase (2012 to 2013);
- Construction and Pre-Commissioning Phase (2013 to 2018);
- Operational Phase (2018 to 2065); and
- Decommissioning Phase (2065 onwards).

Unless otherwise indicated, the temporal boundaries of this assessment are assumed to be the life of the Project (i.e. 50 years).

---

6 First gas from Pipeline #1 is scheduled for late 2015, and all four pipelines are expected to be fully operational by the end of 2017.

17.5 Baseline Data

17.5.1 Methodology and Data

Following the scoping exercise, the next step was to establish the present condition of the scoped-in services as well as broad trends in their provision and use. The baseline provides an analysis of the existing condition of an ecosystem and the services it provides in the absence of the Project, taking into account external factors (i.e. not related to the Project) that may affect future service provision including, for example, climate change, population growth, and changes in land management. Ultimately, the baseline provides a counterfactual or reference scenario from which the impacts of the Project can be measured and covers:

- Current provision of services and how the habitat / land cover supports their delivery;
- The importance of ecosystem services to beneficiaries; and
- How ecosystem services and the benefits they provide are likely to change in future in the absence of the Project.

The data used for the baseline assessment was obtained from a wide range of sources including secondary sources (i.e. existing data including government or academic reports etc.) and primary sources (i.e. new data collected through interviews, field surveys, and stakeholder engagement activities as described in Chapter 6 Stakeholder Engagement).

Information collected during the baseline data collection stage revealed locally important ecosystem services which were not included in the initial scoping exercise, as well as some services initially thought to be important which were found not to be of significant value. As data was collected, the outcomes of the original scoping exercise were updated to ensure that these more accurately reflected the importance of each of the ecosystem services to beneficiaries as suggested by the evidence from the baseline data analysis.

The remainder of this section sets out the data sources in more detail and the limitations of the assessment in terms of the availability of data collected.

17.5.2 Secondary Data

Secondary data and information was obtained through a literature review of relevant peer-reviewed journal articles, research reports, newspaper articles, and publically available databases.

17.5.3 Data Gaps

Due to the fact that the importance of services provided by different ecosystems depends upon how people interact with and value them, the analysis revealed a number of information gaps in relation to the provision and use of services which were not captured through secondary data sources.
17.5.4 Primary Data and Baseline Surveys

In light of the data gaps that emerged from the review of secondary data, a data collection exercise was undertaken which sought to supplement the secondary data gaps as well as to verify and ground-truth the secondary data available. Primary data on ecosystem services was collected during field visits in 2012 and 2013. These visits included: stakeholder meetings; observations of conditions; and meetings and interviews with local government authorities, local businesses including fisheries enterprises representatives, and local landowners.

Since ecosystem services represent the intersection of the natural and human environment, this chapter also draws upon the baseline information and analysis conducted in other relevant chapters of the ESIA. Any gaps in the baseline data relating to ecosystem services were discussed with the relevant technical chapter specialists in case the information was readily available and/or could be obtained through on-going data collection and stakeholder engagement. In order to ensure a comprehensive and collaborative approach to this process, a workshop was held with the technical specialists from each of the environmental and social disciplines covered in the ESIA to discuss the baseline, impacts, and mitigation sections of this chapter. Following the workshop, the collaborative approach was continued with an on-going dialogue with each of the specialists and reviews of the assessment in this chapter being undertaken by the relevant specialists as necessary.

17.5.5 Data Assumptions and Limitations

Accurate, quantifiable data on the use of ecosystem services is used where possible (e.g. loss of potential crop yield), however, for many ecosystem services the data were not available to establish a detailed and quantifiable metric in terms of baseline provision or use for each ecosystem service.

While this is a potential limitation, it does not significantly undermine the results of the assessment since the ecosystem services assessment refers to and builds upon the assessments undertaken in each chapter of the ESIA which use measurable metrics for assessing changes in the natural environment. The emphasis of this assessment is placed on drawing together the other chapters in the ESIA to assess the impacts on the well-being of beneficiaries resulting from changes in the natural environment. As such, the ecosystem services assessment aims to quantify changes in well-being as a result of changes in the provision of ecosystem services.

Due to the fact that there is a high degree of variance between the values different beneficiaries attach to different services, measuring well-being impacts using a single metric across all services and beneficiaries is a difficult task. One approach is to use economic valuation techniques to estimate the value of changes in well-being resulting from changes in ecosystem service provision in monetary terms.

However, due to the need for detailed, high quality primary data to establish reliable economic valuation estimates, and the time consuming nature of undertaking such primary data collection exercises, it is considered beyond the scope of an ESIA to carry out an economic valuation of ecosystem service use.
In light of this, the value of services provided by Affected Ecosystems has been assessed in a qualitative manner through stakeholder engagement exercises, expert discussion, and literature review. Where residual impacts are identified on priority ecosystem services which require compensation, economic valuation may be considered to evaluate the effectiveness of proposed mitigation and/or the value of economic displacement and the appropriate level of compensation.

17.6 Baseline Characteristics

17.6.1 Crops

**Definition:**
The provision of cultivated plants or agricultural products harvested by people for human consumption.

Krasnodar Krai is one of the leading agricultural regions in the country and is commonly referred to as “the granary of Russia” (Ref. 17.27). Agriculture and the food industry are important sectors of the region’s economy, with agriculture, hunting, and forestry contributing 12.6% of Gross Value Added\(^7\) in 2011. Within Anapa Resort Town, the sector is the fourth largest in terms of employment; making up 4.7% of the workforce (although this is down from 6% in 2006) (Chapter 14 Socio-Economics).

The largest agricultural organisation based in the Local Area is Agrifirm Kavkaz\(^8\). Kavkaz owns 1,975 hectares of land; around 400 ha of which are planted with vineyards and produce around 10-11 tonnes of grapes per ha. Depending on the season up to 100 people are employed by Kavkaz, including 40 – 70 workers cultivating and harvesting vineyards and 30 office staff and other workers. Around 30-40 of those employed are seasonal workers who come from Dagestan every year in April and return to Dagestan in November. The migrant workers live in portable cabins located near the new Varvarovka cemetery.

There is another winery based in the Local Area of similar size called Russkya Loza (1,580 hectares) based partly in Varvarovka and partly in Supsekh, which employs approximately 50 workers in Supsekh Rural District and a further 7 to 8 in Gai Kodzor Rural District (Ref. 17.28; Ref. 17.29). This vineyard is not directly impacted by land acquisition associated with the Project.

---

\(^7\) Gross Value Added is a measure of the contribution to GDP made by an individual producer, industry, or sector and is calculated by the value of output minus the value of intermediate consumption.

\(^8\) Agrifirm Kavkaz is owned by a parent company – Fond Yug – which is a property development company with two subsidiaries – Agrifirm Kavkaz and Kavkaz Winery. Ultimately Fond Yug owns the land; although the winery land is in effect owned and managed by Agrifirm Kavkaz. Kavkaz Winery is a separate company which makes and retails the wine.
Of those employed in the viticulture industry, the most vulnerable to any changes in provision of this ecosystem service are likely to be migrant workers who are typically employed on a seasonal basis living in portable cabins nearby the vineyards.

Within the Affected Ecosystems the predominant land uses are agriculture (owned by Agrifirm Kavkaz), and woodland (owned and administered by the Russian Federation State Forestry Fund) (Figure 17.8). The land within the Project Area consists almost entirely of agricultural land, with the only exception being a strip of forest that separates two large agricultural fields. There is also a much smaller area of forest that falls within the boundary of the microtunnel construction site.

Historically, agricultural land in the Affected Ecosystems was planted with vineyards although the land is now a mixture of fallow fields, scrub, and abandoned vineyard. The exception to this is the proposed optional transfer site and the land within the temporary construction area for the Varvarovka Bypass Road. This land is currently productively used as vineyard but is also within the confines of a proposed luxury residential development known as Chateau Club Village; the plans for which would retain as much of the vineyard as possible with the exception of sites for the construction of luxury residential homes. The areas where vines appear to have been eradicated due to the ageing of the plants are now either scrub or fallow fields. It was confirmed by an Agrifirm Kavkaz staff member during stakeholder engagement that the majority of the planted vineyards within the construction corridor, transfer sites and right of way had been abandoned in the last two to three years. This includes a range of mature and young (i.e. recently planted) vineyards (see Chapter 14 Socio-Economics).

The vineyards owned by Agrifirm Kavkaz are used to grow grapes for commercial wine production which is mostly sold locally, but also within the Russian Federation. The vineyards do not form a significant part of the local tourism industry (i.e. they are not a tourist attraction) unlike Abrau-Dyurso (located on the shore of Lake Abrau, 14 kilometres west of Novorossiysk) which lies at the centre of Russia’s most important wine-growing region. The settlement was founded in 1870 as a royal winery to provide wine for the Tsar’s household and developed a reputation for producing sparkling wine marketed under the name of Sovetskoye Shampanskoye which translates as “Soviet Champagne” or “Champagne for the people” (Ref. 17.30).

© URS Infrastructure & Environment UK Limited
Climate projections suggest that the changing climate may impact the suitability of the region for agriculture and viticulture. In the last fifteen years, climate change has made it possible to expand winter grain production in Russia. More recently, however, the increasing incidence of drought and floods has begun to negatively affect agricultural production and offset the gains made through winter expansion (Ref. 17.27).

Due to a lack of detailed climate change projections in the Krasnodar region it is difficult to predict the likely impacts on agriculture in the Local Area with any certainty. However, a qualitative survey of the impacts on crop production and agricultural livelihoods under climate change was undertaken by Oxfam and the recorded observations of farmers across the Krasnodar Krai region may provide relevant insight (Ref. 17.27):

- Weather is increasingly becoming “unpredictable”;
- Harsher, damper climate with precipitation more unevenly distributed through the year;
- Longer, colder, and damper springs;
- Hotter, more arid summers with air temperatures reaching 40°C and soil 60°C;
- More radical temperature changes especially during spring to summer; and
- Stronger winds in winters, springs, and summers which farmers relate to deforestation.

In addition to observational evidence, a recent study of the impact of climate change on global wine production found that it is likely to lead to significant changes in the productivity of current wine-producing regions (Ref. 17.31). The study forecasts a radical shift in wine production with the total area suitable for viticulture decreasing between 25-73% in major wine producing regions by 2050, including parts of the Krasnodar Krai region and potentially the Local Area (Figure 17.9).
As such, in the absence of any adaptation measures, climate change may mean that the productivity of agriculture, and particularly viticulture, in the Local Area could decline in future (although more detailed modelling is needed to be certain). In order to adapt to the changing conditions it may therefore be necessary to shift towards more drought resistant crops (maize, millet, etc.), invest in irrigation infrastructure, and increase the adoption of new technologies.

The impact of such changes is likely to be greatest on small household farmers who may lack the resources necessary to invest in such adaption strategies, as well as on the viticulture industry since wine grapes are particularly sensitive to subtle shifts in temperature, rain, and sunshine. The subsequent increase in demand for irrigation may also lead to increasing pressures on water supplies within the Local Area (see Section 17.6.3).

For further details see Chapter 14 Socio-Economics.

### 17.6.2 Capture Fisheries

**Definition:**
The capture of wild fish for consumption and recreation purposes through trawling and other non-farming methods.
The Russian Black Sea fishery has undergone significant change in the last 40-50 years. While average annual catches ranged between 65,000 and 80,000 tonnes in the mid-1970s and 80s, by 2011 this had dropped by more than half to 30,900 tonnes. There are a number of factors that have led to this decline, including pollution, the introduction of invasive species (notably the predatory ctenophore *Mnemiopsis leidyi*), overfishing, and the decapitalisation of the Russian fishing fleet and associated onshore infrastructure and facilities following the break-up of the Soviet Union.

Most fishing takes place within Russian territorial waters (i.e. up to 12 nautical miles (22.2 km) from the mean low-water mark) (Ref. 17.32). The Azov Fisheries Research Institute recognises two administrative fishing zones within the area that extend from the Strait of Kerch (in the north) to Arkhipo-Osipovka, southeast of Novorossiysk. One of these, the Kerch-Taman zone, which stretches from the Kerch Strait to Cape Utrish, encompasses the entire nearshore section of the Project as well as some of the landfall and offshore sections. The second area, known as the Caucasus zone, stretches from Cape Utrish to the mouth of the Psou River at the border with Georgia. These zones are approximately equal in area, but different in terms of bioresources and productivity. Of the two zones, the most productive is the Kerch-Taman zone. This is reflected in the fact that approximately 96% of the total Russian Black Sea catch comes from waters bordering Krasnodar Krai.

The contribution of fisheries to the regional economy (of Krasnodar Krai) is small (around 0.1% in 2009) (Ref. 17.33). In recent years the size of the fishing fleet has contracted from around 30 vessels in the period 2003-2006 to around 16 in 2013 (Ref. 17.33) and the number of commercial entities engaged in fishing has decreased from 19 to 14 over the same period (Ref. 17.32). The fishery sector can nevertheless make an important contribution to sustaining the livelihoods of certain individuals and families, as well as having historical and cultural significance.

Fishing is also evident and has been observed in Anapa. Based on observations, it is most likely that this tends to be for recreation, rather than as a primary means to support livelihoods. However, according to local officials there may be some isolated but unrecorded instances of fishing to support or supplement livelihoods, although the officials were not able to provide any records or specific examples (Chapter 14 Socio-Economics).

There are around eight commercial fishing enterprises operating within the Russian Black Sea fishery between Temryuk and Novorossiysk, employing around 425 people. The two largest entities operating within the Kerch-Taman zone are RPK Briz (who employ around 30 staff, operating 1 trawler and 5 smaller boats) and OOO RAM (who employ around 14 staff, operating 1 trawler and 3 smaller boats). Most of their catch is sold in Anapa itself in various markets and other outlets, and some as far away as Krasnodar. While other enterprises are active in the Kerch-Taman zone these are generally relatively small (employing 2-3 people each) or they mostly fish in other areas (e.g. the Azov Sea) with only occasional trips into the Kerch-Taman zone.

Due to the anoxic nature of the Black Sea (see Section 17.6.6) species diversity declines with depth. Marine surveys undertaken for the ESIA recorded 64 species at a depth of less than 25 m and only 8 species in deeper water (50-85 m) (Chapter 12 Marine Ecology).
concentration of Russian Black Sea fishing activity / effort reflects this species gradient, with most commercial fishing occurring in nearshore waters out to a depth of around 100 m.

Anchovy (*Engraulis encrasicolus*) and sprat (*Sprattus sprattus*) are the most important species in the fishery, comprising 28% and 25% of the Russian Black Sea catch respectively, with an additional 16% from red mullet and 12% from whiting. Most of the commercial fish stocks in the Russian sector of the Black Sea show some seasonal movement and migration which are key factors in the fishery and also are relevant to the Project.

In the main, the sprat stocks spawn in the upper layers (at depths of 100-150 m) of the open waters of the Black Sea off the coast of Russia. This takes place in the winter months, from October to March, at which point the shoals are highly dispersed and not fished commercially. After spawning, the adults move inshore to the feeding grounds from mid-March to early June where they form shoals over the continental shelf in waters of 20 to 80 m depth. Sprats feed mainly on plankton in the upper layers of the water. These shoals form the main commercial concentrations for a trawl fishery in this area from April to September. The major concentrations are found on the continental shelf of the Kerch-Taman region as far south as Anapa and Utrish and also between Novorossiysk and Arkhipo-Osipovka. The narrow continental shelf further south restricts the aggregation of sprats and the fishery is therefore sparser.

The Black Sea anchovy feeds predominantly in the northwest area of the Black Sea in the vicinity of the rich inflows from rivers such as the Dnieper and Danube. In autumn they migrate southeast to winter and spawn along the coast of Turkey and Georgia. Only occasionally do concentrations occur in Russian waters so this has not normally formed part of the fishery in Russia (Ref. 17.32).

The Azov anchovy pass through the Straits of Kerch in March to early April and into the Sea of Azov where they both feed and spawn during the summer although some remain in the Black Sea to spawn over the continental shelf. During autumn they migrate to their wintering grounds, passing southwards along the coast to winter mainly in the southern Black Sea near Sochi and Adler and into Georgian waters. Thus, most of the Russian anchovy fishery is seasonal, targeting the migrating shoals in spring and autumn. To exploit these stocks, cooperative fishing brigades set nets across the main migration route. There are also some purse seiners operating in the fishery as well as mid-water trawlers.

While not featuring significantly in the composition of catches in the Russian Black Sea fishery (the annual catch is only around 240 t), horse mackerel spawn and feed in shallow water during the summer then move south, overwintering in the area around Sochi and the Georgian shelf, returning north in the summer. One of their main summer feeding grounds is the continental shelf around Anapa (see Appendix 14.1 Fisheries Study). The horse mackerel stock is currently recovering after a sharp decline in the early 1990s. They are reported to be difficult to catch due to their mobility during migration and the main fishery is during winter using attractant lights at night with lift nets from small vessels.

---

9 A purse seine is a very long net, which falls as a curtain from a floating head rope, that is use to surround shoals of open water fish. After encirclement, the bottom rope is pulled tight to trap the fish in the 'purse'. It never comes into contact with the sea bed.
Benthic and demersal fish typically migrate less extensively than pelagic species. Nevertheless, there are some appreciable migrations. The Black Sea turbot, *Scophthalmus maeoticus*, is probably the most valuable species with an international price of around $4,000 / t, although it is now very scarce with an average annual catch of 10.6 t over the last five years. The species tends to move from deeper water in the winter into the shallower zones to spawn and feed during April to September. Protection of this stock was one reason for the designation of the Anapa Bank, a protected area constituting 33% of the Kerch-Taman fishing zone, within which seasonal fishing restrictions apply to ensure stock recovery. The area in which fishing is prohibited has, however, been reduced.

A recent (2012) assessment of Black Sea fish stocks by the European Commission Scientific, Technical, and Economic Committee for Fisheries (STECF) found that sprat, anchovy, and whiting stocks are all subject to overfishing, although a lack of data prevented projections of stocks in the medium term (Ref. 17.34). The assessment also reported that the Black Sea turbot stock was at an historical low (10% of 1970 levels) and therefore classed it as severely depleted as a result of unsustainable exploitation. Given the dramatic decline in the stock of turbot in the Black Sea, and the extremely high annual estimates of fishing mortality, STECF recommended that there should be no fisheries for turbot and individuals caught unintentionally should be released. In order to avoid further declines in turbot stock, STECF also recommended that an international management plan should be initiated to restore spawning stock biomass to the level capable of producing maximum sustainable yield (Ref. 17.34).

The most common demersal species, the whiting (*Merlangus merlangus*) usually occurs from 30 to 100 m depth where the water is cooler. Whiting show very few systematic movements with the exception that the younger individuals move inshore. Dense concentrations of whiting are to be found on the Anapa Bank, Southern Ozereevka and Arkhipo-Osipovka. The annual catch has been very variable from 3 t in 1997 to 655 t in 2002 but in the recent decade catches have been relatively small, at some 50 to 100 t, largely due to a lack of demand (Ref. 17.32).

The other main bottom-dwelling target species is the red mullet or ‘barabulka’ (*Mullus barbatus*) which occurs in two populations, one sedentary, remaining around Sochi and Georgia, and one migratory which moves seasonally along the coast as far as the Straits of Kerch. The average annual catch is around 110 tonnes.

In addition to the offshore fisheries there is also a degree of nearshore fishing activity, these consist of fish traps and fixed nets. The closest traps are owned by the Zao Moresky Club, who operate out of Bolshoi Utrish. They operate at least four fixed traps and a mussel farm, all serviced by a fleet of small vessels located approximately 5 km to the south of the Project Area. The fish traps are designed to trap migrating fish, the most significant to the Zao Moresky club being the red mullet, with catches of around 50 t per year. Around 3 t of horse mackerel and small amounts of pontiac shad (about 0.5 t) are also caught.

The fisheries of the Russian Black Sea shelf as a whole are very seasonal, ultimately relating to the migratory movements of the target stocks described above. This is reinforced by the regulations of the Federal Fisheries Agency (Ref. 17.35) and the Azov Fisheries Research Institute (Ref. 17.36). The lifecycle of fish species in the Black Sea and the nature of Black Sea currents mean that certain species within the Kerch-Taman zone can be important to fishing industries operating across the entire Black Sea. For example, the life-cycle of the anchovy
requires it to migrate extensively across the Black Sea, passing most coastal sections as well as open water, with important life stages (e.g. spawning, larvae, wintering, feeding) occurring in many different locations. Both migratory and non-migratory species regularly cross national territorial waters and EEZ boundaries. Any potential impacts on species stocks in the marine environment may therefore have the potential to influence fisheries in other Black Sea countries (Chapter 21 Transboundary Impact Assessment).

For further details see Chapter 14 Socio-Economics, Appendix 14.1 Fisheries Study and Chapter 12 Marine Ecology.

17.6.3 Water Supply

The main inland freshwater body is the Shingar River, the source of which is a spring within the town of Varvarovka to the north of the proposed Pipeline route. The river is approximately 5.5 km long and runs parallel to the coastline. The river’s channel in the upper reaches is stony and the basin territory is distinguished by a high level of wooded coverage.

The proposed Pipeline route crosses surface waters in two places: microtunneling underneath the Shingar River and crossing an unnamed tributary which drains the Graphova Gap (a small gully). For both water courses, intermittent low-water periods are typical. Low water flows are observed in the brief intervals of inter-flood periods during the whole year and longer periods of low flows are experienced in the summer period, during which the watercourses sometimes dry out and water in the channels stands in individual pools.

The hydrogeology of the area is characterised by a shallow alluvial aquifer overlying a carbonate aquifer. The alluvial aquifer is present along the narrow river valleys of the Shingar River and an unnamed tributary of the Sukko River. The anticipated depth to the water table varies between ground level to a few metres deep along the valley floors (where groundwater is in hydraulic continuity between the alluvium and carbonate aquifers) and up to 100 m beneath the higher areas. Groundwater recharge is through rainfall and discharge from surface water courses along their upper reaches. In the lower reaches of the valleys groundwater is likely to discharge to the river system and ephemeral springs during periods of high rainfall and corresponding high groundwater levels.

In addition to the Project itself, there are a number of beneficiaries of the ground and surface water resources in the area including the Russkaya compressor station which plans to abstract groundwater for drinking and industrial purposes from an aquifer approximately 3 to 4 km north of the Project Area. This abstraction is likely to be hydraulically upgradient from the Project Area and the Project does not lie within the designated sanitary protection zone for this abstraction.

There is a well owned by the Ministry of Defence located near the settlement of Sukko drawing from an aquifer downgradient of the Project Area (Figure 17.10). The Project is dependent upon this resource for freshwater required in construction activities. While the water supply is owned by the Ministry of Defence it also utilised by third parties. Water may only be abstracted from
the Sukko source between October and April; it is understood that the restriction on summer abstraction is in place to prevent derogation of the aquifer (Chapter 8 Soils, Groundwater and Surface Water).

There are no licensed surface water abstractions for drinking water within or downstream of the Project Area. There is, however, a small impoundment on the watercourse in the Graphova Gap located upstream of the proposed RoW crossing. This impoundment structure retains surface water flows to enable abstraction by the Agrifirm Kavkaz for use in viticulture. There is also a natural spring known as St. Barbara’s Source reputed to have healing powers located in Varvarovka (upstream of the Project Area) which is of cultural importance to people living in the Local Area and to visitors.

There is considerable variation amongst communities in the Local Area with respect to access to mains water supply. While all households in Supsekh and Gai Kodzor have mains water supply and 80% in Varvarovka, only 50% of households have access in Sukko with the remaining 50% obtaining water from wells on their property (Chapter 14 Socio Economics).

Across Russia as a whole, climate change is predicted to lead to an increase in surface water flows and precipitation levels. However, within the Krasnodar region, there is a projected decline in water availability (Figure 17.11); although there are no available projections specific to the Local Area (Ref. 17.37). Attempts to maintain or increase wine productivity in the face of a changing climate may lead to an increase in water use for irrigation as well as to cool grapes through misting or sprinkling. These factors could result in increasing pressure on water resources within the Local Area which could be exacerbated by population growth and growing demand for water for other uses.
Figure 17.10 Predicted Changes in Annual Runoff During the Period 2041–2060 (values are given in % change relative to the period 1980-1999 and dots denote areas where two thirds of the models show changes of the same sign) (Ref. 17.37)

For further details see Chapter 8 Soils, Groundwater and Surface Water.

17.6.4 Hazard Regulation

**Definition:**

The capacity of the natural environment to regulate water, soil, and sediment transfer so as to:
maintain the integrity of land surfaces in order to reduce the hazards associated with mass
movements (e.g. landslides and slumping), coastal erosion, and flooding; maintain "intact" soil cover
and low suspended sediment loads in fluvial systems; and retain and store water and delay release
from the land surface and attenuation of peaks as flood water passes through river networks to
reduce the risks associated with runoff and flooding (Ref. 17.19).

There are a number of hazards associated with the Local Area, including gravity-induced
landslides, linear erosion, mudslides, and flooding. The key features within the Affected
Ecosystems which contribute to the regulation of natural hazards include vegetation which binds
together soil particles and attenuates surface water flows; Phaeozem soils which absorb water
and play an important role in flow regulation; and coastal habitats including underwater
sandbars, beaches, and cliffs which dissipate energy from waves and regulate levels of coastal
erosion and flooding.

Watercourses flowing through the Affected Ecosystems are predominantly precipitation fed,
with frequent and short floods. Surface waters are partly recharged from high groundwater
tables (often associated with springs) and flows typically peak during winter months when
rainfall is highest. In addition to the natural watercourses, there are artificial drainage ditches
which are used to manage flood risk locally.

Phaeozem soils in the Affected Ecosystems have a high water absorption capacity and play a
key role in water regulation. During summer months when precipitation is limited, most surface
water permeates the underlying soils and further reduces flow through the rivers. This typically
results in watercourses becoming dry or the formation of discrete ponds within the river bed.

Storms and the associated surface run-off can lead to soil erosion, subsequent aggradation and
accumulation of sediments on lower slopes, and degradation of water quality due to an increase
in suspended sediments. Forested areas where trees line the valley slopes form a canopy to
protect soils, take up water and reduce the amount of surface run-off, and reduce soil erosion
as the roots bind together soil particles.

The sudden formation of mudflow and mudrock flows is possible in the valleys of the Shingar
River and the unnamed tributary of the Sukko River. Retrospective analysis indicates that
mudflows occur once every several (5 to 7) years (Chapter 7 Physical and Geophysical
Environment). Mudflows are typically triggered by intense rainfall events and/or prolonged
periods of rain (Ref. 17.38).

Erosional processes are associated with the coastal cliff zone. The relatively narrow beach
provides limited protection to the base of the cliffs against direct wave action. Waves also assist
in the removal of material at the toe of the cliffs resulting in periodic landsliding and slumping
events. The risk of landslide activity is enhanced by seismic activity in the vicinity of the
Affected Ecosystems which typically has potential to cause earthquakes of magnitude 5 to 6 on the Richter Scale.

The wave climate adjacent to the Russian coastline of the Black Sea is heavily influenced by the shallow continental shelf which results in smaller, primarily wind driven waves. The typical maximum wave height in the marine Affected Ecosystems is around 2.9 m, reaching 4.8 m in 1 in 100 years. Short-term sea level variations are also associated with varying meteorological conditions and can result in localised sea level surges of up to 1 m, although they are typically less than 40 cm (Chapter 7 Physical and Geophysical Environment).

The risk of natural hazards to local communities is relatively low and natural ecosystems play a role in regulating the extent of such hazards through erosion and water flow regulation arising from soils and trees, as well as providing some level of protection from storms through coastal cliffs and beaches. The beneficiaries of this service are therefore widespread and diffuse, including landowners, residents, and workers in the area who benefit from the regulation of flooding and erosion, and users of the beach and coastal area for recreational uses and livelihoods. The Project also benefits to some extent from the regulation of such processes.

Climate change in Russia is projected to lead to an increase in the frequency of hazard events including floods, droughts, wild fires, and mudflows (Ref. 17.37). Across Russia as a whole, there was an annual increase in the number of hazardous weather events from 1991–2005 of 6.3% and this increasing trend is expected to continue (although there is a lack of projections available for the Local Area). Sea levels in the Black Sea have been rising steadily since the 1920s, with the rise becoming much more rapid since the mid-1980s (around 2 cm per year) (Ref. 17.37). The changing climate, together with further development within the Local Area which requires clearance of vegetation and increases use of impermeable surfaces, are likely to increase the pressure on the functioning of this ecosystem service and lead to higher rates of flooding, erosion, and mud slides in future.

For further details see Chapter 7 Physical and Geophysical Environment and Chapter 8 Soils, Groundwater and Surface Water.
17.6.5  Air Quality Regulation

Definition:

The natural environment influences atmospheric concentrations of air pollutants and their deposition to land and water surfaces through the removal and detoxification of pollutants from the atmosphere. Gases and particles, for example, are deposited to ecosystem (primarily plant) surfaces and pollutant gases enter leaves through stomata. The extent of this removal depends on a number of factors, including the turbulence of the air above the ecosystem (taller vegetation has a greater efficiency), the duration of leaf cover (evergreen tree species are more effective than deciduous species), and the stomatal aperture of the vegetation (deposition may decrease under drought conditions). The ability of ecosystems to provide this service also depends upon the extent of other pollutant sources (both manmade and natural) and the resulting concentration of pollutants in the atmosphere. If, for example, the concentration exceeds the assimilative capacity of an ecosystem to absorb and detoxify pollutants, critical thresholds can be reached above which the ecosystem can no longer provide this service. As such, this service depends on both the regulatory capacity of ecosystems and the inputs of pollutants to this system from other sources (Ref. 17.19).

There are several residential areas within the Local Area which are likely to be dependent on the regulation of air quality. These include residential areas in Rassvet, a kindergarten and school within Varvarovka, high schools in Gai Kodzor and Supsekh, outpatient facilities within local towns including Varvarovka, a hospital in Anapa, and the Shingari and Don holiday resorts (see Section 17.6.8).

In addition to residential receptors, there are also several nationally and internationally protected habitat sites that may be considered sensitive to air emissions attributed to the Project including the Utrish state national reserve, which is located approximately 3.2 km southeast of the microtunneling location, and critical (but not designated) habitat through which the landfall section will be constructed.

Further, the Anapa Resort Town (ART) municipal district was designated a health resort town in 1957 and is designated at a Russian federal level as a Specially Protected Natural Area (SPNA), for the purpose of providing a “health improving (spa) resort area”. The SPNA designation entails a series of development control regimes that apply to different zones within the SPNA area, the general purpose of which is to control development and protect the area from any activities that may cause adverse impact on the natural therapeutic resources and sanitary conditions of the resort town area.

As such, ART markets itself as a health tourism destination in an area with unique air and water quality (Ref 17.24). As a result, one of the main branches of the economy is the health resort complex which includes over 150 institutions (including 44 recreation facilities for children), about 250 hotels, and more than 2,000 private landlords (Ref. 17.39). Beneficiaries of this service are therefore likely to include people visiting the area for the air quality benefits, and anyone with respiratory conditions who lives in or visits the Local Area is likely to be particularly vulnerable to any impacts on air quality regulation.

Data provided by the Krasnodar Regional Centre for Hydrometeorology and Environmental Monitoring found that concentrations of pollutants in the Local Area generally comply with
national and IFC limits, with the exception of NO₂ and particulate matter which are high. However, these values are derived from short term monitoring undertaken in central Anapa, Varvarovka, and Gostagaevskaya which are unlikely to be representative of the land in the vicinity of the Project Area which is more rural in character (Chapter 9 Air Quality).

Diffusion tube monitoring was undertaken for the ESIA and covered a greater spatial extent of the Local Area. The results easily complied with national and IFC guidelines for the parameters monitored; with NO₂ concentrations between 14-31% of the limit (considerably less than the concentration measured at the automated stations).

The main source of emissions in the Anapa and Krasnodar regions are road vehicles which contribute an estimated 92% of total atmospheric emissions in the Krasnodar region. Almost all of the remaining emissions are from industrial sources (7.9%), of which the main sources in the region are the Krasnodar Thermoelectric Power Plant, AO Novorostsement in Novorossiysk, and the Krasnodar combined cycle gas turbine Combined Heat and Power Plant.

The high levels of forest coverage within the Local Area are likely to play an important role in regulating air quality by directly absorbing pollutants such as volatile organic compounds and particulate matter (Refs 17.40 and 17.41). Studies have estimated that a single hectare of mixed forest can remove 15 tonnes of particulates per year from the air (Ref. 17.42), although this varies according to tree species, stomatal conductance, environmental conditions, and pollutant concentration in the atmosphere (Ref. 17.43). As set out in Table 17.6 in Section 17.6.10, there is approximately 490 ha of woodland cover within the Affected Ecosystems (including Shiblyak, Mesophillic forest, and Juniper woodlands), which suggests they could absorb up to 7,440 tonnes of pollutants each year.

The ability of ecosystems to regulate air quality is likely to come under increasing pressure in the Local Area due to economic development and population growth which can lead to increases in atmospheric pollutants and the clearance of vegetation which plays a role in regulating pollutants. Further, climate change and associated warmer temperatures can decrease the absorption rates of vegetation and thereby reduce the effectiveness of ecosystems at regulating air quality (Ref. 17.44).

For further details see Chapter 9 Air Quality.
17.6.6 Water Quality Regulation

Definition:
The natural environment can regulate marine and fresh water quality through processes such as: plant and microbial nutrient uptake, pollutant sequestration in soil and marine and freshwater sediments, biofiltration from marine and freshwater organisms, breakdown of organic pollutants, acidity buffering, and denitrification. These processes contribute to the detoxification and purification of water used for human uses such as drinking, agriculture, industrial uses, fisheries, tourism, and recreation (Ref. 17.19).

Similar to the air quality regulation service, the ability of ecosystems to regulate water quality depends on the extent to which ecosystems can purify water by filtering pollutants from, and reducing inputs into, water resources, and the level of pollutant inputs and pressures placed on the natural environment and its capacity to regulate.

Within the Local Area there are several freshwater resources for which quality is of particular importance to the local population, including the well at Sukko and St. Barbara’s Source, Varvarovka. Water quality is also important for any direct abstractors of groundwater in the Local Area as any contamination can have lasting impacts on human health. There are also a number of mineral water deposits located in the ART and the high quality of these mineral water sources in ART has supported the development of a health tourism industry and designation of the region as an SPNA (see Section 17.6.5).

As part of the ESIA a number of water quality surveys were undertaken in the Local Area (Chapter 8 Soils, Groundwater and Surface Water). Groundwater samples were taken from three springs and hydrocarbons were detected in one of the samples at a concentration which exceeds the maximum permissible concentration for drinking and domestic water quality (Ref. 17.45). There was no evidence of contamination from other pollutants exceeding the national limit values. Four surface water quality samples were taken and for all samples, elevated copper levels exceeded the standards for fisheries. Water in the Shingar River exceeded the fisheries standard levels for several parameters including: phosphate, copper, nitrites, nitrates, sulphates, mercury, phenols, and oil products. Several parameters (including phosphate, copper, sulphate, ammonia and phenols) exceeded the fisheries standard levels in the Graphova Gap.

Marine water quality in the Affected Ecosystems plays an important role in supporting the recreational / tourism industry. Of particular importance in the Local Area are people engaged in water sports, bathing, scuba diving operations, and the Shingari and Don holiday complexes for which recreational water use is an important facility for visitors (see Section 15.6.8). Marine water quality is also important for human health, with contaminants in the marine environment potentially having significant impacts on those exposed to concentrations of contaminants, toxic algae blooms, or through bioaccumulation of contaminants and subsequent entry into human food sources.

Marine water quality surveys undertaken for the ESIA found that phosphate and nitrate content did not exceed maximum allowable concentrations for fisheries (Ref. 17.46). Generally, suspended solids concentrations varied between 0.2 and 7 milligrams per litre, the main sources
Chapter 17 Ecosystem Services

of which are from river waters, wave induced disturbance of seabed sediments, and deposition of airborne particles (Chapter 7 Physical and Geophysical Environment). Surveys also indicated a low degree of eutrophication due to the prevalence of brown algae over green algae, the high population of pollution-intolerant species, and the low number of epiphytes (algae that grow on other species).

Many contaminants in the marine environment are able to bind to sediments (thereby being locked up indefinitely) and surveys of the Affected Ecosystems identified the presence of contaminants in marine sediments including petroleum hydrocarbons, phenols, anionic surfactants, and heavy metals (Chapter 7 Physical and Geophysical Environment).

Contaminants can also be accumulated by organisms such as invertebrates and macroalgae. Benthic macroalgae and grasses (macrophytobenthos), in particular, enrich water with oxygen, take up dissolved organic matter, and assimilate heavy metal contaminants, thereby increasing the quality of coastal waters (Ref. 17.47 and Ref. 17.48). Macrophytobenthos are also critical components of the marine ecosystem as primary producers, providing food and shelter to a wide variety of organisms either as living plant matter or detritus.

The bivalve *Mytilaster lineatus* is one of the main components of seaweed thickets throughout the Black Sea due to its high settlement density and resistance to pollution. This is of wider significance because *M. lineatus* is therefore the main provider of natural bio-filtration along the Black Sea coast and can be present in high densities.

Surveys of the Affected Ecosystems found that, in shallow waters (up to 2-3 m depth), macroalgae communities are characterised by a relatively low diversity and biomass. In the mid photic zone (between 3-10 m) algal communities are dominated by large structural brown algae. While at depths over 10-15 m, communities of *Phyllophora* and *Codium vermilara* are observed. The greatest diversity of algae is found in the mid photic zone which supports a high species diversity and considerable biomass of the mussel *Mytilaster lineatus* in some areas.

In deeper waters, marine water quality in the Black Sea is anoxic. Waters with hypoxic or entirely anoxic conditions are typically incapable of sustaining permanent populations of species dependant on aerobic respiration. Oxygen depletion occurs in layers below 80 to 150 m and hydrogen sulphide (H2S) builds up below these depths. Consequently, the potential for significant marine life occurring at depths of greater than 200 m within the Black Sea is likely to be limited to those organisms capable of anaerobic respiration (e.g. chemosynthetic life). Anaerobic respiration typically produces H2S and methane (CH4) as a by-product. Concentrations of H2S are known to be elevated within the bottom waters of the Black Sea.

Marine water quality throughout the Black Sea has been affected by rapid economic development and a lack of adequate management of marine resources in the later decades of the 20th Century, resulting in major environmental and ecological changes in the Black Sea ecosystem. In particular, eutrophication, due to excessive levels of nitrogen from land based sources into the Black Sea, and the introduction of invasive species, have given rise to massive increases in primary production and a shift in the abundance and composition of phytoplankton species. Larger and more frequent algal blooms have increased sedimentation of decaying plants and detritus to the seabed inducing a sharp decline of dissolved oxygen and a silting of benthic communities in many areas. Increased incidence of harmful algal blooms have led to
the death of many fish and the increased turbidity of the water column has reduced light availability to macroalgae in deeper waters.

It is possible that pressures on the capacity of ecosystems to regulate water quality will increase in future due to a combination of climate change (which may lead to rising water temperatures, acidification of marine water, and concentration of surface water pollutants during periods of lower flows e.g. in summer) and increasing development (particularly any expansion in the agricultural industry and subsequent increase in surface water runoff from vineyard areas which could lead to eutrophication in both marine and freshwater environments).

However, since the early 2000s the governments of the Black Sea coastal states have adopted a basin-wide approach to pollution reduction and enhancement of cooperation of coastal and non-coastal states towards a strategic goal of achieving the ecological status of the Black Sea similar to the one observed in the 1960s (Ref. 17.49). Pollution pressure from land based sources, although still intense, shows a decreasing trend and some improvements in ecological status have been observed. This coordinated action, if continued, may offset and reduce the pressures on water quality within the Local Area.

For further information see Chapter 7 Physical and Geophysical Environment, Chapter 8 Soils, Groundwater and Surface Water, Chapter 12 Marine Ecology, and Chapter 14 Socio-Economics.

17.6.7 Soil Quality Regulation

Definition:
The capacity of natural processes to regulate soil quality through the storage and degradation of organic matter leading to replenishment of the topsoil layer; storing, degrading, and transforming materials such as nutrients and contaminants; mediating exchange of gases to the atmosphere; and maintaining a structural composition which supports growth of plants and water flow regulation.

There are a number of soil types within the Local Area including Cambisols, Phaeozem soils, Arenosols, Fluvisols, Abrazems / Regosols, and Anthropogenic soils. These soil types provide important services to a range of beneficiaries.

Agricultural areas (principally vineyards) in the Local Area are predominantly located on Arenosols and Abrazem / Regosol soils. These soils are predominantly used for agricultural production of grapes. Grapes are perennial crops and cultivation involves ploughing and tillage which can lead to soil compaction. These soils can also experience a homogenizing effect due to the fact that there is no organic matter influx which results in differences between the soils being evened out in terms of the vegetation contribution to humus- and soil-formation (Ref. 17.50).

Owners of land within the Affected Ecosystems (principally Agrifirm Kavkaz) benefit from the economic rents associated with good quality soil and productive use in agriculture. The regulation of soil quality by natural processes also provides a service to workers who come into contact with soils. Workers and owners of land adjacent to the Affected Ecosystems may also
benefit from soil quality regulation processes since, depending on the physical properties of the soil (including soil porosity, soil potential for pollutant absorption, and soil saturation); contamination of soil within the Affected Ecosystems could lead to contaminant migration and impacts on soils in adjacent areas of land.

Phaeozem soils comprise a soft organic rich topsoil layer covered in vegetation and have a high water absorption capacity. As a result, they play a role in regulating water flows in the Local Area. The soil quality regulation service is therefore linked to hazard regulation and all households living within the area benefit from an indirect reduction in flood risk due to the role of soil quality regulation. These soils are structurally prone to compaction and erosion, and are vulnerable to contamination through surface spills.

Fluvisol soils are present in the valley bottoms and also play a role in the hydrological cycle. These soils are associated with watercourses and valley bottoms and can act as pathways for the movement of chemical contaminants into groundwater and surface water. As such, the regulation of soil quality is also linked to water quality processes. Fluvisol soils also support populations of the critically endangered Nikolski’s tortoise.

Surveys of soil quality within the Local Area found elevated concentrations (above maximum permissible thresholds) of arsenic, copper, lead, zinc, benzo(a)pyrene, polychlorinated biphenyl, and pesticides. The sources could be natural or manmade (Chapter 8 Soils, Groundwater and Surface Water). There are also areas of soils used for informal waste disposal which could potentially be contaminated with substances such as asbestos. The contaminants present in the soil are known to be harmful to human health under certain exposure scenarios and concentrations appear to be highest in agricultural areas, at watercourse crossings, and near existing roads (Chapter 8 Soils, Groundwater and Surface Water).

Expansion of the agriculture and viticulture industry within the Local Area is likely to increase pressure on soil quality regulation. Further, increases in traffic and vehicle emissions could lead to greater deposition of airborne particles which could also increase pressure on soils.

For further information see Chapter 8 Soils, Groundwater and Surface Water.

17.6.8 Tourism and Recreation Values

Definition:
Natural environments such as woodlands, rivers, beaches, and marine ecosystems provide a variety of tourism and recreation opportunities such as: hiking, walking, camping, horse riding, health based tourism, scuba diving, picnicking, and beach based recreation.

The ART municipal district is a designated ‘resort town’ which provides for a regime of measures intended to safeguard the district’s important tourism attraction features. Tourism is the most important industry in the ART municipal district and visitor numbers and accommodation facilities have displayed continuing strong growth over recent years (Chapter 14 Socio-Economics).
The town of Anapa is the key focus for tourist activity and accommodation within the municipal district and has a large number of hotels, restaurants and associated infrastructure to support the tourism economy. Sukko is also an important area and has a beach which is used by local residents and tourists as well as offering camping, horse riding, and fishing. Sukko beach is the principal and only easily accessible public beach between the town of Anapa and Utrish Specially Protected Natural Area (SPNA). Paragliding is undertaken off the cliffs of Sukko with gliders flying out to sea and special recreational programmes for children are carried out involving sea trips, diving, and environmental tourism / education (Figure 17.12).

While most of the land based tourism activity takes place within and around Anapa or Sukko, rather than within the Affected Ecosystems themselves, the “Mountains of the Caucasus” trail (which involves hiking, waterfalls, and camping) starts in Anapa and finishes in Utrish, passing over a hill under which the microtunneling will take place. There is also a business based in Varvarovka, with approximately 30 horses, which offers horse-riding tours including a route that traverses the Agrifirm Kavkaz fields in the direction of a lake north of Sukko. The business has approximately 20 customers per day in the summer.

Within the marine environment, the area around Sukko beach and the nearby waters are used for sun bathing, swimming, fishing, and yachting. There is also a scuba dive operator in Anapa who utilises a number of sites along the coast. The closest site to the Affected Ecosystems is the ship “Gordipiya” which sank in February 1943. The ship is on an even keel at a depth of 18 metres and has become an artificial reef providing habitat for mussels.

Approximately 1.5 km south of the Project Area are two neighbouring holiday complexes (tourist resorts) known as Shingari and Don. Shingari is a privately owned complex of holiday residences built on the coastal cliff top adjacent to the Project Area. There is a private beach belonging to Shingari immediately below the complex, accessible by steps from the resort.

The Shingari resort receives around 6,000-7,000 people each year with the peak season lasting from June till the beginning of October (housing up to 380 people at a time). Most visits are arranged through company bookings and visitors are from different regions of Russia, with around 3% coming from other countries within the former Soviet Union. Around 150 people are employed by Shingari although this rises to 200 during peak season. Most employees are local and reside in Anapa.

Don is located on the north side of the roadway running between Varvarovka and Sukko. Don is a holiday complex owned by Russian Railways and is only open to its employees (or people invited by Russian Railways). Don is located opposite Shingari on the north side of the roadway running between Varvarovka and Sukko, and its residents also have access to the beach via a path that runs on the outside of the Shingari complex perimeter boundary.

© URS Infrastructure & Environment UK Limited

This document is for the purpose of providing information on the proposed tourism and recreational resources within the local area associated with the Russian Sector of South Stream Offshore Pipeline Project. The map shows key locations such as Varvarovka, Sukko, Gai-Kovdor, Don resort, and Sukko beach. The project includes proposed landfall section pipelines, landfall facilities, proposed microtunnels, proposed offshore pipelines, construction corridor, microtunnel entry shaft, microtunnel exit pit, and the United Gas Supply System. The map also indicates the boundaries of the state nature reserve "Utrish" and the coastal path of the Mountains of the Caucasus Trail. The Sunken scow "Gordipia" is also marked within a 1km radius of the Project.
Beaches along the coast are important for recreation and tourism in the wider region and ecosystem processes underpin the continued provision and evolution of such natural landforms. The Anapa Bay Bar, for example, which lies within the wider region, is a 50 km long accumulation of sand which forms a natural beach barrier separating the system of firths and salty lakes from the Black Sea. The continuous strip of sandy beach, several hundred metres in width in places, is a natural reserve of significant recreational importance for Russia and makes Anapa a popular holiday destination.

Several mollusc species play a role in the lithodynamic processes of the marine environment and the accumulation of sand and shell plays a significant role in the balance of the beach and bottom sediments. According to unpublished data obtained in 2010 by the Department of the Coastline of the Southern Branch of the Institute of Oceanology of the Russian Academy of Sciences, the concentration of carbonates of mollusc origin, coming into the sand of the Anapa Bay Bar as shells, may reach up to 53% (Ref. 17.51).

The venus clam (*Chamelea gallina*), found in soft sediment habitats at depths of 5 to 10 m, is the major source of the shelly sand component of the beaches of Anapa Bay. The annual input of carbonates of biogenic original to the bay bar is estimated to be 3,500 tons, 91% from *Chamelea gallina*, the remainder from a range of other molluscs including the bivalve *Donax trunculus* and the gastropod snail *Rapana venosa*. These organisms contribute to the composition and aesthetic value of beaches in the wider region and thereby support the use and enjoyment of beach resources by beneficiaries.

The large scale ecological changes witnessed throughout the Black Sea have had a significant impact on benthic ecosystems including the diversity, abundance, and biomass of most mollusc species (Ref. 17.52). For example, only four of the 11 species of mollusc found in the shelly sand of the Anapa beach are now found as living individuals (Ref. 17.51) and the distribution, abundance and biomass of *Chamelea gallina* have declined significantly since the 1990s (Ref. 17.52). As such, in recent decades the supply of biogenic carbonate to the sands of the bar has been appreciably reduced, exacerbating an on-going process of erosion in the area. Over the past 40 years, the morphology of the Anapa spit barrier has changed probably due to a combination of natural processes and the impact of economic activities such as the sand recovery (Ref. 17.3) and the construction of a great number of recreation complexes at Anapa.

While there are no direct projections of the future growth of the tourism or recreation sectors in the region, the current steady growth is expected to continue and may experience an increase due to the impacts of the 2014 Winter Olympics in Sochi.

For further information see *Chapter 14 Socio-Economics*. 
The environmental setting of the Local Area is characterised by a deeply undulating, extensively wooded landscape. The woodland is interspersed with open, cultivated land comprising vineyards, orchards, and meadows. The coastline provides a combination of steep slopes, cliffs, rocky outcrops, beach, and maritime vegetation fronting the Black Sea which is valued for its combination of wildness and far-reaching, panoramic views of the coastline and open sea. As identified in Chapter 13 Landscape and Visual Assessment, the visual quality of the woodland and agricultural landscape is important for both residents and tourists who visit the region.

Baseline surveys identified a number of archaeological and cultural heritage sites in the Local Area. The earliest evidence for human activity in the area comprises Upper Palaeolithic stone tools found in the vicinity of Supsekh. There are also four Bronze Age kurgans (burial mounds) located on high points between the villages of Varvarovka and Supsekh, over 4.5 km north of the Project Area. A group of rural villas and farmsteads dating to the Antique period have been identified around 1.6 km northwest of Varvarovka. A burial dated to the 6th to 4th century BC is recorded between the villages of Varvarovka and Supsekh, located over 4 km north of the Project Area.

There is also a designated kurgan located approximately 50 m northwest of the pipeline microtunnel section which dates from the Antique to medieval period and is identified as critical cultural heritage. While there is extensive tourist interest in Krasnodar's Bronze Age dolmens, some of which are subject to tourist pilgrimages and offerings, no such activities have been observed to be associated with this kurgan site and the value is likely to be primarily scientific (Chapter 16 Cultural Heritage).

There is a designated statue of DS Kalinin, Hero of the Soviet Union and commander of the 2nd Reconnaissance Detachment Staff of the Black Sea Fleet (1910-1943), who was killed in action when leading a seaborne assault south of the village of Supsekh in May 1943. This event is commemorated with a major memorial erected close to the Anapa-Sukko road, 750 m east of the Project Area. Designated war memorials in the village of Gai-Kodzor commemorate Soviet soldiers killed during the Great Patriotic War and villagers executed at Gai-Kodzor in August and December 1942. At Varvarovka, there are monuments to the Soviet marines and villagers killed by invaders in 1942-1943, and to countrymen who died in the Great Patriotic War. Varvarovka village cemetery includes the common grave of Soviet soldiers and civilians killed in 1942-1943.
There are a number of cemeteries associated with the villages to the north of the Project. The closest of these to the Project Area is the Varvarovka village cemetery, a mixed Armenian and Russian cemetery approximately 398 m north of the northern pipeline centre-line and close to the Gazprom Invest Road (permanent access road) and 100 m west of the South Stream Transport temporary access road to the microtunnel site. The Varvarovka Armenian and Russian cemetery lies on the eastern edge of Varvarovka village, close to Agrifirm Kavkaz vineyards. The cemetery is extensive and divided into family plots. It includes the common grave of Soviet soldiers and civilians killed in the fighting and executed by the fascist invaders in 1942 and 1943 (National Monument No. 380). Further away from the Project Area are the Varvarovka Armenian cemetery, approximately 2.1 km northwest of the connection with the Russian gas network, and the Gai Kodzor Armenian cemetery and church, approximately 5.6 km northeast of the connection with the Russian gas network.

A new Russian Orthodox church is under construction at Varvarovka. The Armenian Apostolic Church of St. Sarkis (St. Sergius) at Gai-Kodzor was built in 1997 and a new Armenian church is also under construction on the same site. Adjacent to the churches is a Gai-Kodzor Armenian khachkar cross stone, erected in 1992. It depicts two phoenix birds, symbolizing the friendship between the Armenian and Russian peoples. Khachkars or Armenian cross-stones are carved outdoor stone stelae which act as a focal point for worship, as memorial stones and as relics facilitating communication between the secular and divine. They constitute a distinctive symbol of the identity of Armenian communities at home and abroad. The symbolism and craftsmanship of khachkars was inscribed on the UNESCO Representative List of the Intangible Cultural Heritage of Humanity in 2010.

Specific natural resources with a cultural or spiritual role within the area include St. Barbara’s Source, Varvarovka, a natural spring reputed to have healing powers and the focus of an annual procession and ceremonies during the Feast of the Theophany in January. Attendees include local parishioners and pilgrims from further afield. St. Barbara’s Source is located around 1.9 km northwest of the Project Area. There is a sacred tree located west of the road between Sukko and Anapa. The species is Blackthorn (Prunus spinosa) and prayer ribbons and cloth rags are suspended from its branches. Sacred trees and groves occur in many cultures across the world. In the Kuban region, the custom may date back to Circassian / Adyghe traditions, which in turn overlie earlier practices.

Socially significant religious and secular events celebrated in the region include national and international festivals, processions, village days, and commemorations of military and historical people and events who have made a significant contribution to the development of Russia and Kuban. On Victory Day (9 May) and Anapa region Liberation Day (21 September) there are rallies, vigils, and wreath- and flower-laying ceremonies at monuments and war memorials. A festival is held at the khachkar in the last week of every May, involving representatives from all communities in the Anapa area.

---

10 Note, there is some overlap with the Water Supply and Water Quality services, in order to avoid double counting, impacts on St. Barbara’s Source will be assessed in the Water Quality section.
There are several cultural groups based in the Local Area including the Center of Armenian Culture, Council of Veterans, and Cossack Society. There are also a number of amateur associations and clubs such as folk dancing, choirs, and orchestral groups. Traditional Kuban Cossack culture and local folk arts and crafts are being revived with state support, and include weaving, traditional embroidery, pottery, woodworking, basketry, leather manufacture, wool felting and blacksmithing; masters of these arts are honoured with the title “Master of arts and crafts of Kuban”.

The Local Area is characterised by an agricultural and coastal landscape which plays a role in the cultural identity of the area and of the aesthetic qualities of the landscape. Gastronomic specialities include local wine (Gai-Kodzor Vineyards, first harvested in 2008), as well as Kuban produce including pickles, boiled pork, lard, blinis (pancakes), and pastries. Distinctive local cultural elements of note include traditional Cossack costume, which dates back to the late 19th century. Baseline data collection did not identify any groups who have a particular interest in the natural environment (such as bird watching groups). If such groups are present, it is likely that such activities would take place within the Utrish protected area.

Marine surveys revealed that there are three archaeological objects located within 150 m of the Project Area, including: a modern period aircraft wing, a medieval period ceramic amphora, and a medieval to post-medieval period wooden shipwreck.

None of these sites were identified as being visited by local dive operators and their value is likely to be predominantly scientific. Due to the anoxic conditions in the Black Sea, which inhibit corrosion and microbial degradation, the preservation potential for objects is greatly enhanced below a water depth of 120 m to 200 m. As such, the nearshore and offshore sections have high potential for featuring archaeological elements such as: prehistoric sites that became submerged as a result of the Black Sea flooding; historic coastal settlements; shipwrecks and maritime structures; and remains associated with 19th and 20th century conflict.

For further information see Chapter 16 Cultural Heritage.

**17.6.10 Wild Species Diversity**

**Definition:**

People derive value from interaction with wild species as well as from knowledge of their continued existence, these values may extend locally, regionally, nationally, or even globally. Species are considered to be locally important if they are valued by local communities for reasons in addition to the other ecosystem services they may provide. For example, the importance of mussel species in providing water quality regulation services is discussed in the water quality chapter, however, some species do not provide any identifiable services and are not identified as being of conservation importance at any level. Nevertheless, they may be of importance to local communities and any impacts on their populations (such as the loss of commonly seen birds or butterflies) could impact the well-being of local beneficiaries. Species are considered to be regionally important if they are listed on the Krasnodar Red data list, nationally important if listed on the Russian Federation Red data list, and globally important if listed on the IUCN Red data list as being vulnerable, endangered, or critically endangered.
Terrestrial Affected Ecosystems

The most common concern raised by stakeholders during consultation (raised 33 times) was the Project’s potentially negative impact on the natural environment, including the marine environment, the coastline, onshore valuable habitat area (e.g. the mountain area of the Kilberov Canyon), juniper trees, and local wildlife around the proposed compressor station.

There are a total of eight natural 11 and two modified 12 habitat types within the terrestrial Affected Ecosystems. While none of these habitats are protected sites designated for nature conservation, all forest or woodland habitat are identified as "protective forests", as defined within the Forest Code of the Russian Federation (Chapter 11 Terrestrial Ecology). This includes all mesophilic forest, shiblyak, and juniper woodland. These forests are recognised as important features within the environment, as they perform important functions, such as protection of water resources and soils, and recreational spaces for local communities. This designation is not strictly related to the forest's intrinsic "biodiversity value", but rather is associated with the ecosystem services they provide.

Table 17.6 lists these habitats and the area of each habitat falling within the Affected Ecosystems. Full descriptions of each of these habitats are provided in Chapter 11 Terrestrial Ecology.

11 As set out in IFC PS 6, natural habitats are areas composed of viable assemblages of plant and/or animal species of largely native origin, and/or where human activity has not essentially modified an area's primary ecological functions and species composition.

12 As set out in IFC PS6, modified habitats are areas that may contain a large proportion of plant and/or animal species of non-native origin, and/or where human activity has substantially modified an area's primary ecological functions and species composition.

*Modified habitats

Complete.

The habitats within the terrestrial Affected Ecosystems have the potential to support a number of flora and fauna species which are of local value and some of which are of regional, national, and global conservation significance.

In terms of locally important species, juniper trees were identified to be of particular value to local communities. During consultation, stakeholders asked about the felling of juniper trees in both the Varvarovka / Sukko community meetings and the Anapa roundtable meeting. Stakeholders asked whether the juniper trees would be re-planted or the area restored (Chapter 6 Stakeholder Engagement).

In addition, surveys undertaken for the ESIA found 26 plant species listed within the Red Data Book of Krasnodor Krai, including two juniper species. These flora species make up part of the Juniper scrub / woodland, Shiblyak, and Tomillyar habitats which provide important habitat and play a role in air, water quality, and hazard regulation.

Regarding fauna, the Nikolski’s tortoise is known to be present within areas of Shiblyak and Mesophilic forest. Nikolski’s tortoise is a regionally, nationally, and internationally threatened species that is listed as critically endangered on the IUCN Red Data List. A population survey, undertaken during October and November 2013 recorded a total of 51 individual Nikolski’s tortoises and the total population size is estimated to be around 150 individuals.

The major threats to this species include loss of habitat due to the expansion of agriculture and urbanisation. There is also evidence of local use of this species through the collection of tortoises for bush meat and the pet trade. Local ecologists identified the persecution of tortoises for their meat and carapaces as the most critical threat facing the species in the locality. In particular, inspectors of the Utrish reserve have reported isolated incidents of vagrants collecting tortoises for food and observations have been made of the illegal trade in Mediterranean tortoises in shops and markets of several towns on the outskirts of the Krasnodor region, including animal shops in Novorossisk (Ref. 17.53).

Other species of conservation importance identified include 38 species of invertebrate; six breeding bird species; and a range of mammal species including twelve species of bat (see Chapter 11 Terrestrial Ecology for a full list of species).

Due to the presence of two specific habitat types (Mesophilic forest and Tomillyar) and several endangered and endemic species, the Affected Ecosystems were identified as supporting Critical Habitat.
A Special Protected Natural Area is also located within the Local Area. The site is of federal significance and is located in Krasnodar Krai approximately 4 km south-east of the Project Area. The total reserve area is around 10,000 hectares and covers both the terrestrial and marine environments. It is adjoined to the south-east coast of the Abrau peninsula and the site is known to support a diverse range of flora and fauna including protected and notable plant species, herpetofauna (including Nikolski’s tortoise), mammals, birds, and invertebrates. The reserve extends into the Black Sea and supports various notable ichthyofauna and marine habitats. The site was first established in 1987 to preserve the Mediterranean landscapes and their characteristic ecosystems which are typical of the North-Western Black Sea coast area of the Russian Federation.

As such, when viewed within the context of the Local Area, there are relatively large expanses of similar or higher quality habitat than are present within the Affected Ecosystems which are likely to be better suited to supporting any threatened plant and animal species.

**Marine Affected Ecosystems**

Potential impacts on the marine environment were raised by local communities and NGOs during consultation ([Chapter 6 Stakeholder Consultation](#)) suggesting that marine habitats and species within them are of importance to people living in the Local Area.

There are three broad habitat types in the Black Sea, including:

- **Surface waters** (typically 0 to 50 m water depth) which are well oxygenated, have a fairly low salinity, and have historically supported large populations of pelagic fish. There are a number of different benthic habitat types within these shallow waters including: rocky substrates which allow the development of macroalgal beds that in turn support a highly diverse array of fauna; sandy sediments which support a range of infaunal communities, typically bivalve dominated; and mud sediments which support infaunal communities;

- **Mid-depth waters** (approximately 50 to 100 m water depth) which show decreasing oxygen concentrations and increasing salinity. Benthic habitats at these depths are often muddy sediments; and

- **Deep waters** (below about 150 to 200 m) where conditions are anoxic. Muddy sediments predominate in deeper waters, and while little is known about the benthos of the deep Black Sea, chemosynthetic bacteria can occur here.

Within the marine Affected Ecosystems, surveys carried out for the ESIA found several species of macroalgae that are listed in the Red Data Book of Krasnodar Krai. Eight fish species of conservation importance have been observed from the Russian Black Sea coastline caught in fixed gear at commercial fishing stations and could potentially be found within the marine Affected Ecosystems. Of particular note are the Russian sturgeon (*Acipenser gueldenstaedti*) and stellate sturgeon (*Acipenser stellatus*) which are listed by the IUCN as critically endangered (although they are not included in the Red Books of either the Russian Federation or Krasnodar Krai).

Long snouted seahorse, currently listed as data deficient by the IUCN (formerly considered vulnerable), were observed at depths of 1 to 30 m throughout the marine Affected Ecosystems. Seahorses have been significantly exploited by manufacturers of souvenir products and were
initially included in the Red Data Book of the Krasnodar Territory as a protective measure. However, the population in the Black Sea has increased significantly and it was removed. It remains on a list of species that are prohibited for catching by the Fishing Rules for the Sea of Azov-Black Sea commercial fishing region.

A further species which may be found within the marine Affected Ecosystems is the tub gurnard. This species may have local importance in the manufacturer of souvenirs and to underwater hunters. Due to a combination of human exploitation, pollution of the marine environment, and illegal fishing, the species has become increasingly rare in the last decade. As a result, the tub gurnard has been entered into the Red Data Books of the Russian Federation and the Krasnodar Territory to ensure its strict protection.

Several bird species of conservation importance were also observed in the marine Affected Ecosystems including the Black-throated diver, Mediterranean gull, and Mediterranean shearwater. An additional protected species that is likely to occur but not directly observed in surveys is the gull-billed tern. This species is in both the Russian and Krasnodar Red Data Books.

Cetacean species of conservation importance off the Russian coast include the harbour porpoise (*Phocoena phocoena relicta*), bottlenose dolphin (*Tursiops truncatus ponticus*), and common dolphin (*Delphinus delphis ponticus*). All three are protected on a national level by environmental legislation and governmental decrees and were observed in surveys undertaken for the ESIA.

Charismatic and visible species such as dolphins are also likely to have local importance to people in the Local Area. Within Anapa, for example, there is a dolphinarium which offers dolphin therapy sessions to children with development difficulties which aim to: improve coordination, develop motor skills, stabilise mood, raise self-confidence, develop communication, and encourage thought development (Ref. 17.54).

During the 1980s to early 2000s, the number of facilities for dolphin shows and "swim with dolphins" programmes greatly increased in Black Sea countries. The export of bottlenose dolphins from Russia and Ukraine for permanent and seasonal shows also expanded to over 20 countries in Europe and the Middle East. According to CITES statistics, at least 92 individuals were removed from the Black Sea region during 1990-1999 and Russia reportedly has exported at least 66 for traveling shows since 1997.

Due to the presence of threatened species in the marine Affected Ecosystems the area has been identified as Tier 2 critical habitat as defined by the IFC. It should be noted that the Project Area does not, per se, represent particular habitat that is not replicated elsewhere in the Russian Black Sea; it is merely part of a wider zone that meets the requisite criteria (*Chapter 12 Marine Ecology*).

For further information see *Chapter 11 Terrestrial Ecology* and *Chapter 12 Marine Ecology*. 
17.6.11 Baseline Summary

A summary of the baseline conditions of the ten key ecosystem services is provided in Table 17.7. Likely future trends are indicated as follows: ↗ increasing provision; ↘ decreasing provision; ↔ no overall change in provision; and ± some increases and some decreases in provision. The importance of the ecosystem service to beneficiaries is indicated by: ⬇ high importance; ⬇ moderate importance; ⬇ low importance; and ⬇ negligible importance.

#### 17.7 Impact Assessment

#### 17.7.1 Impact Assessment Methodology

The assessment of impacts on ecosystem services broadly follows the approach set out in Chapter 3 Impact Assessment Methodology. It follows the same steps and uses the same assessment criteria but differs in one important respect: it assesses impacts from the point of view of the ecosystem service beneficiaries. The impact is therefore measured as the change in human well-being (relative to the baseline) as a result of a change in the level of provision of an ecosystem service.

The nature and significance of impacts are determined using a set of criteria that reflect the value of ecosystem services to beneficiaries, the resilience of ecosystems and their beneficiaries to change, and the extent, duration, reversibility, and frequency of the impacts. These criteria are explained more fully in the sections that follow.

#### 17.7.1.1 Impact Assessment Criteria

**Receptor Sensitivity**

Receptor sensitivity is determined using information from the baseline and provides a detailed understanding of the importance of each ecosystem service to its respective beneficiaries, taking account of:

The value of ecosystem services to beneficiaries, i.e.:

- The extent to which beneficiaries are dependent on the ecosystem service (e.g. whether fishing is undertaken occasionally as a recreational activity or regularly as an important part of livelihoods); and

- The scarcity value of the ecosystem service (e.g. the availability of suitable alternatives or substitutes) and how readily replaceable it is considering accessibility and affordability.

And the resilience of ecosystems and beneficiaries to change, i.e.:
• The **sensitivity of the ecosystem** to change (e.g. as a result of climate change, population pressures, etc.). This will depend on *inter alia* the existing condition of the ecosystem, its functions, and its thresholds. For example, some fish species (such as sturgeon) are particularly sensitive to changes in water temperature (Ref. 17.55); and

• The **sensitivity of beneficiaries** to changes in ecosystem service provision. This will depend on *inter alia* beneficiaries’ existing endowments of, or access to, factors such as financial, human, physical, natural, and institutional capital. For example, poorer rural households who collect water directly from the environment through household wells are likely to be more sensitive to changes in the supply and quality of their water than wealthier households in urban centres who are connected to a public water supply system.

The extent to which an ecosystem service fulfils each of these criteria is scored on a four point scale as shown in Table 17.8. Note that receptor sensitivity is independent of Project impacts and relates to the existing situation and the capacity of ecosystems and ecosystem service beneficiaries to adapt to any type of change (e.g. climate change, population growth, etc.).

**Table 17.8 Criteria Used to Determine Receptor Sensitivity**

### Impact Magnitude

The assessment of Project impacts on ecosystem services follows the methodology described in Chapter 3 Impact Assessment. The magnitude of each of the identified impacts on ecosystem services is evaluated on the basis of the following criteria:

- The **severity of the impact** on the well-being of ecosystem service beneficiaries;
- The **reversibility** of the impact (i.e. how quickly is the ecosystem able to recover from the impact); and, based on this,
- The **duration** of the impact on beneficiaries; and
- The **frequency** with which ecosystem service beneficiaries are affected by the impacts of Project activities.

Each impact is scored against each of the criteria on a four point scale as shown in Table 17.10 below.
### Table 17.10 Criteria for Determining Impact Magnitude

17.7.1.2 Impact Significance

Once the receptor sensitivity and impact magnitude for each of the ecosystem services is estimated they are then combined to estimate the impact significance using the impacts significance matrix set out in Table 17.12 which is consistent with the overall approach to determining impact significance as set out in Chapter 3 Impact Assessment Methodology.

URS-EIA-REP-204635 17-77
Based upon the resulting impact significance score, *priority ecosystem services* i.e. those upon which the Project is likely to have a significant impact and which result in adverse impacts on beneficiaries, and/or those upon which the Project is directly dependent for its operations are determined as follows:

- **Not Significant** to **Low** impact significance – not a priority service and no mitigation required beyond that which is set out in other chapters; and
- **Moderate** to **High** impact significance – priority service and further mitigation measures required to maintain the value and functionality of the affected service.

Once the data necessary to inform the impact assessment was collated and entered into the ESIVI tool, the technical specialists from each of the environmental and social disciplines covered in the ESIA were invited to participate in a workshop in order to:

- Draw on the specialist knowledge of each of the participants to determine impact magnitude and impact significance and to identify which services should be considered priority ecosystem services;
- Identify where further information may be required to inform the ecosystem services assessment and/or where the ecosystem services assessment could inform the assessments presented in the other chapters of the ESIA particularly in relation to livelihoods, health, safety, and cultural heritage; and
- Begin to identify appropriate mitigation measures which aim to maintain the value and functionality of priority services using the mitigation hierarchy.

Following the workshop, the residual impact assessment was completed. This follows the same process as described above in terms of assessing impact magnitude but includes consideration of the effectiveness of the proposed mitigation measures. Where the proposed measures are not able to avoid or reduce impacts on priority services, or to restore ecosystem service functionality and value, then appropriate forms and levels of compensation have been discussed with the local communities.

### 17.7.2 Assessment of Potential Impacts: Construction and Pre-Commissioning

#### 17.7.2.1 Introduction

The following sections provide a description of the nature and significance of Project impacts on ecosystem services and their beneficiaries during the Construction and Pre-Commissioning Phase. A detailed breakdown of the scoring assigned to each ecosystem service is provided in Appendix 17.3 Impact Assessment – Construction and Pre-Commissioning.
17.7.2.2 Assessment of Potential Impacts (pre-mitigation)

Crops

The service considered in this assessment is the provision of crops grown on agricultural land within the Affected Ecosystems. The key beneficiaries include:

- Agrifirm Kavkaz;
- Consumers of wine produced by Agrifirm Kavkaz; and
- Migrant workers temporarily living in the Local Area who depend on seasonal employment by Agrifirm Kavkaz.

Due to the relatively small extent of productive agricultural land which will be cleared by the Project, together with the fact that much of the land is scrub, fallow land, or abandoned vineyard (Table 17.13), it is unlikely that the Project will lead to any impact on the ability of consumers to purchase wine.

Further, since there is no provision under Russian Federal law for compulsory land purchase, South Stream Transport cannot expropriate land to make it available to the Project. South Stream Transport must therefore reach an agreement with land owners to acquire or temporarily use land (e.g. by leasing) through negotiated settlement according to a Project Land Acquisition Plan.

As land will be acquired by way of negotiated settlement, within the context of a legal system that does not sanction expropriation or other compulsory procedures, any impacts on the respective land owners will be identified and compensated accordingly as part of the negotiated settlement. It is therefore considered that there will not be any impacts on well-being associated with either the permanent or temporary change of use of the land needing to be acquired (Chapter 14 Socio-Economics).

As such, the impact assessment therefore focuses on workers employed by Agrifirm Kavkaz.

The Project activities which could impact provision of this service include:

- Clearance of vegetation within the Affected Ecosystems;
- Restrictions on re-vegetation and land use post-clearance;
- Smothering of crops due to dust released during construction activities; and
- Leaks or spills which could contaminate soils in the Affected Ecosystems and reduce productivity (impacts on soils are assessed in the Soil Quality Regulation section below).

Receptor Sensitivity

Due to the distance to which migrant workers travel to work on the vineyards within the Affected Ecosystems, it is likely that they are highly dependent on this service for employment and livelihoods. Agrifirm Kavkaz does have other land holdings in the Local Area (total land holdings are around 1,975 ha) which are currently fallow or uncultivated and could potentially be used as alternative locations for grape cultivation. While cultivation of such land could provide alternative sources of employment for workers and there are other potential alternative sources of employment (such as in the tourism sector), there is no certainty that jobs would be available on a like for like basis. As such, it is considered that there are some alternatives for this service.
Vineyard ecosystem services are considered to be moderately sensitive to change due to the sensitivity of grape production to shifts in temperature, rain, sunshine, and soil conditions. Further, the resilience of the ecosystem to change may come under increasing pressure as a result of climate change. While the effects of climate change may threaten the longer term sustainability of wine production, the winery itself is considered to be fairly resilient to relatively small changes in access to factors of production (particularly land) as it owns (and could acquire) other land holdings which could potentially be brought into production. However, migrant workers are likely to be highly vulnerable to any change in employment and may have limited capacity to adapt to such changes.

The overall receptor sensitivity is therefore considered to be high.

Impact Magnitude

Construction of the Project will require clearance of approximately 53.5 ha of agricultural land for construction of the landfall facilities, the access road, and for the Pipeline Right-of-Way. Of the land to be cleared, around 41.69 ha (78%) is scrub, fallow land, or recently abandoned vineyard and approximately 11.81 ha (12%) is productive vineyard.

Around 8.7 ha (16%) of agricultural land will be taken out of agricultural use permanently and 23.75 ha (44%) will require temporary clearance before being returned to the land owner following the construction period. The remaining 21.05 ha (39%) will be returned to the landowners but future use will be restricted. For this land within the Pipeline Right-of-Way, no deep rooting trees or permanent crops will be allowed to grow back following construction, although bushes and other shallow rooted vegetation, including grape vines, will be allowed to be replanted and the land will be returned to landowners.

However, it is considered unlikely that the land owner or manager would replant vines or other long term cultures within the Pipeline Right-of-Way because of the possibility that they may need to be dug up at any time in the operational phase to allow for maintenance of the pipelines, thereby causing substantial disruption. Therefore on balance, it is considered that the land that would remain within the right of way would not be likely to be replanted with vines (even if the precedent can allow for it) but will be able to be planted with seasonal crops.

Table 17.13 shows the breakdown by permanent, temporary, and restricted use land take for Kavkaz, according to the existing land use pattern of Agrifirm Kavkaz’s arable land.

<td></td>
<td><strong>53.5</strong></td>
</tr>
</tbody>
</table>
Emissions of dust from construction activities could have a temporary impact on productivity of cultivated land in the Affected Ecosystems although this is likely to be minimal. As such, the main impacts of the Project are likely to arise from a decrease in current and future crop production, and a corresponding decrease in employment opportunities, resulting from the permanent loss of 1.7 ha, and the loss of income and costs of re-establishment following the temporary loss of 10.11 ha of cultivated vineyard. There could also be a reduction in future crop production due to the permanent loss of 7 ha, temporary loss of 10.94 ha, and restricted use of 23.75 ha of scrub, fallow, and abandoned land, although any losses are likely to be minimal.

The limited amount of cultivated land to be cleared means that it is highly unlikely that any loss of land will result in on-going economic displacement of workers, although there could be some temporary displacement during seasons which coincide with construction activities. The total area of vineyard currently under cultivation by Agrifirm Kavkaz is 416 ha and it is understood that there is sufficient land under production, with related tasks that can be undertaken, to ensure that the displaced workforce would be absorbed elsewhere in the vineyard. Part of the land is also set aside for the Chateau development which will require some clearance in the absence of the Project (e.g. for construction of the properties and driveways) and may lead to a change in demand for such labour if the new vineyard owners do not elect to hire migrant workers to cultivate their private plots. As such the magnitude of the impact on well-being is considered to be low.

Most of the land to be cleared for the Project will be able to be replanted with crops following construction allowing ecosystem functionality, crop productivity, and employment opportunities to be restored. For land which is to be replanted for viticulture, vineyard ecosystems are estimated to take around three years (or three growing seasons) to reach a productive state that is sufficient to enable harvesting for the purposes of wine making.

While there will be some loss of crop production due to the permanent clearance of 1.7 ha land for the landfall facilities and an on-going restriction on the ability to cultivate land for viticulture in future, this is likely to be very small. The main impacts are likely to be felt in terms of temporary loss of productive land during the construction period. For workers employed by Agrifirm Kavkaz there is unlikely to be a significant on-going impact on job opportunities although there could be some short term disruption during the construction period. Impacts would be felt periodically during harvests taking place within the construction phase.

The overall impact magnitude is therefore considered to be low (refer to Appendix 17.3 for the scores against each of the magnitude scoring criteria).

**Impact Significance**

In combination, the total impact significance on the crops ecosystem service is therefore judged to be **Moderate** and crops are identified as a priority service during the Construction and Pre-Commissioning Phase.
Capture Fisheries

The service considered in this assessment is the capture of wild fish for consumption and recreational purposes through trawling and other non-farming methods within an area that extends along the coast from the Kerch Strait in the north to Arkhipo-Osipovka in the south. The key beneficiaries are:

- The two main commercial fishing enterprises based in Anapa who operate in the Kerch-Taman fishing zone (RPK Briz and OOO RAM) and their employees;
- A number of smaller commercial fishing organisations operating out of Novorossiysk and Temryuk who fish in the Kerch-Taman zone; and
- Commercial fishing organisations based elsewhere (including other Black Sea countries) that harvest stocks of fish in the Black Sea that may migrate or spawn in waters within the Kerch-Taman zone.

The specific effects of Project pre-commissioning and construction activities which could potentially impact upon capture fisheries include and which were considered in the assessment include:

- Sediment disturbance during dredging, installation of pipelines, pipe-laying, and back-filling;
- Implementation of safety exclusion zones around anchored vehicles (during surveys) and during dredging, installation of pipelines, pipe-laying, back-filling and tie-ins; and
- Disturbance caused by noise, vibration and light from vessels used for surveying, dredging, installation of pipelines, pipe-laying, back-filling, and tie-ins.

Receptor Sensitivity

Given the relatively low importance of fisheries to the local economy, dependence on fisheries is generally low although, for particular individuals working for smaller fishing organisations who have less access to alternative sources of income, the dependence on this service for livelihoods is likely to be higher. Due to the extensive fishing grounds which are used by fishing organisations, the overall dependence on capture fisheries within the Project Area is likely to be low.

The available fishing grounds are extensive (from the Kerch Strait to the mouth of the Psou River on the border with Georgia) and therefore access to fishing grounds other than those within the Project Area are considered to be available. However, given the additional costs of travelling further afield and the declining level of fish stocks generally, the alternative fishing grounds are not considered to be widely available without incurring additional costs (i.e. the fuel used to access fishing grounds that are further afield and the opportunity cost of the additional time spent at sea).

Fish stocks within the Black Sea are sensitive to change and there are recorded declines in a number of species as a result of over-fishing, eutrophication, and the introduction of alien invasive species. The Anapa Bank has been specifically designated as a protected area in order to encourage the replenishment of fish stocks, particularly for the Black Sea turbot whose stocks are presently at historically low levels. As such, the ecosystem is considered highly sensitive to change.
Any change in fish stocks would impact upon all beneficiaries who would either incur greater expenditure in order to travel to alternative fishing grounds further afield or obtain smaller catches. While larger commercial fishing organisations are likely to be able to adapt to such changes by shifting to new fishing grounds, smaller organisations with smaller fleets and less access to technological / financial resources are likely to be more sensitive to any change in provision of this service. Further, due to the poor state of the fishery in terms of vessel age and infrastructure investment, the sector is likely to be highly sensitive to any changes.

Overall receptor sensitivity is assessed as being moderate.

**Impact Magnitude**

A fisheries study was undertaken in order to assess the potential Project impacts on fish stocks and the beneficiaries dependent upon them. The report identified three potential impacts: disturbance to fish through sedimentation from dredging; loss of access to fishing grounds due to the exclusion zone; and noise and light disturbance to fish species (Appendix 14.1).

The first potential impact is seabed sediment dispersion caused by the construction of the microtunnel and the seabed dredging process. Increased sediment may affect fish in two ways: through increased turbidity caused by high suspended sediment concentrations reducing the capacity of visual predators to locate prey; and through sediment settling on the seabed smothering eggs and possible prey items for some benthic feeders as well as restricting the settlement of larvae. Both of these have the potential to reduce the reproductive capacity of fish species causing a reduction in stocks over time or causing fish stocks to relocate elsewhere.

While there will be some disturbance of sediment during the dredging of the exit pits and transition trenches, sediment modelling undertaken for the ESIA shows that the duration of this operation will be approximately 1.5 to 2 days (depending on the scenario assumed). Modelling also shows that, in the most extreme case, the sediment plume disperses rapidly to the lowest detectable level as it is carried down the coast over a 4 to 5 day period. The extent of this sediment disturbance will therefore not be at an intensity or duration that would affect fish species or the ability of beneficiaries to undertake fishing activities.

The second potential impact is the imposition of a safety exclusion zone of approximately 3 km (1.6 NM) radius which will be enforced during construction to avoid incidents with marine traffic. The safety exclusion zone will mean that access to a certain area of the fishing grounds will be lost during construction which could potentially impact on the livelihoods of those in the fishing industry.

However, the loss of access to potential fishing grounds will be minimal relative to the fishing area. An estimate of the shelf area above 100 m depth between Arkhipo-Osipovka and the northerly limit of the Anapa Bank, which is largely coincident with the anchovy feeding grounds, is approximately 2,235 km², while the area of the 3 km exclusion zone around the near shore construction will be around 14 km², less than 0.01% of the shelf area which constitutes the fishing grounds. Interference with the sprat fishery, which is largely confluent with the anchovy grounds, is therefore also unlikely. Further, any loss of fishing area will be less important to the sprat, anchovy, and other pelagic fisheries since they use mid-water methods which are less dependent on specific areas.
More direct impacts might be felt by fishing operations for benthic and demersal species since there will be loss of access to a specific area of habitat. This, however, will be limited to 3 km either side of the works and will cover a relatively small area in relation to the total fishing grounds. The potential for impacts will be further limited due to the absence of any bottom fishing in the area. While smaller vessels can trawl for benthic and demersal species, it is likely that they do this using a midwater trawl setup and fish close to, rather than on, the bottom. In addition, demersal species make up only 9% of the total catch and are normally caught using fixed nets. While the 3 km exclusion zone around the pipe-laying vessel may cause some temporary inconvenience and increased costs due to the need for fishing vessels to avoid the safety exclusion zone around the construction spread, there are unlikely to be any significant impacts on catches or livelihoods.

The greatest potential impact during the Construction and Pre-Commissioning Phase, and the greatest concern outlined by the fishing companies interviewed, is the possible disturbance to fish migration due to noise and vibration.

The fish species migrating along the coast which are most likely to be impacted are anchovy, horse mackerel, and to a lesser extent some of the bottom dwelling species such as migrating red mullet. Anchovy migrate along the coast from the Kerch Strait to the southern wintering areas off Sochi and the coast of Georgia. The main north-south autumn migration is October to November while the return spring migration is April to June. The Pipeline cuts across this line of movement.

The pipe-laying vessel will be a moving source of continuous noise and light. The anticipated noise level from vessels used in the Pipeline construction is between 169 and 192 dB. Using weighted thresholds, it was found that behavioural effects may be apparent in some hearing specialist fish such as sprat in certain situations (though not shad or anchovy because they have a different hearing range). Anchor handling is the activity most likely to generate such responses, and in shallow water may extend up to 260 m from activity, with an affected area of approximately 0.2 km². In deep water, where anchor handling will not take place, the pipe-laying vessel itself may generate similar impacts at a lesser range of approximately 140 m (area of effect approximately 0.06 km²).

As virtually all fishing takes place within 12 NM (equivalent to 21.6 km) of the coast, there should always be an undisturbed corridor of 5 to 6 km through which fish can pass. Moreover, since the vessel lays pipes at between 2.5 and 2.75 km per day over a 21.6 km distance, it should only take around nine days to traverse the fishing zone on the main continental shelf area down to 100 m water depth where the fish migrate. Since the periods of migration of both the anchovy and mackerel are at least 2 months, any disturbance will therefore only be temporary. Fish species are also likely to become habituated to vessel noise sources.

It is further noted that the authorities have put a ban on any construction activity taking place in waters to 100 m depth during the month of May, which coincides with the peak of the main spring anchovy migration, thereby further reducing the likelihood of any impact.

Due to the fact that the vessel will be brightly illuminated at all times, light disturbance could also potentially be an impact, although the attraction effect of light is relatively localised and is...
only a factor at night. As such, any disturbance can be bypassed by migrating fish during the
day.

To provide an overall point of comparison with regard to disturbance from construction
activities, in a similar situation for the North Stream pipeline, monitoring of fish densities
showed no changes attributable to construction and there was no discernible impact on fish
catches over the period (Appendix 14.1).

On the basis of the analysis presented above, it is concluded that there will be no
distinguishable differences in fish catches outside of the normal annual fluctuations and it is
unlikely that the fishing industry will experience a reduction in catch during the Construction
and Pre-commissioning Phase. As such, there are unlikely to be any identifiable impacts on
beneficiary well-being resulting from Project activities.

The impact magnitude is therefore considered to be negligible (refer to Appendix 17.3 for the
scoring against each criterion).

Impact Significance

The overall significance of the impacts of Project activities on capture fisheries is assessed as
being Not Significant and fisheries are not considered to be a priority service requiring
mitigation.

Water (supply)

The service considered in this assessment is the use of ground and surface freshwater resources
provided by, or dependent upon, the Affected Ecosystems. This includes water resources used
throughout the Shingar catchment. The baseline identified a number of beneficiaries using freshwater
resources within the Shingar catchment who are located upstream of the Affected Ecosystems,
including:

- The Russkaya compressor station which abstracts groundwater from a source north of the
  Affected Ecosystems;
- Agrifirm Kavkaz which abstracts water from an impoundment in the Graphova Gap; and
- Visitors to St. Barbara’s source located in Varvarovka.

Due to the hydrological gradient and distance from the Project Area of these abstractions, the Project
is unlikely to lead to any impacts on the provision or use of these water resources and, as such, the
assessment focuses on downstream beneficiaries including:

- The Project itself which is dependent upon the Ministry of Defence well in Sukko; and
- The Ministry of Defence and any households dependent on the water abstracted from their
  well.

The specific Project activities that could affect the water (supply) services provided by or
dependent on the Affected Ecosystems include:

- Construction activities which require dewatering of groundwater resources;
- Abstraction from aquifers for use in construction leading to decreasing groundwater
  levels; and
Alterations to surface water flows during construction due to crossing of surface waters and alterations to vegetation cover.

Receptor Sensitivity

Companies and households abstracting from groundwater resources (including the Project itself) are highly dependent on the water supply for their health, operation, and well-being. Alternative supplies of water are widely available through the use of other aquifers or surface water resources, the public water supply system, or tinkering/piping in supplies from other areas (although the last approach is likely to incur significant environmental and social costs).

The sensitivity of the Affected Ecosystems to change is likely to be moderate. While there are relatively large quantities of water resources available in the Local Area, the aquifer from which the MOD operates a well is under pressure from abstraction and is managed through a licencing system which sets limits on abstraction volumes to ensure sustainable use. Commercial organisations are likely to be of low sensitivity to change as the main direct abstractors (the Project itself and the Ministry of Defence) are likely to have the financial and technological resources to be able to adapt to changes in supply. Residents of Sukko currently drawing water from wells are likely to be of moderate sensitivity as they are reliant on the municipal authorities for any alternative sources of water should the well water sources be affected.

The overall receptor sensitivity is therefore considered to be moderate (refer to Appendix 17.3 for the scoring against each of the magnitude significance criteria).

Impact Magnitude

Construction activities are likely to require groundwater control at certain points. While this may involve dewatering abstractions\textsuperscript{13}, the impacts will be temporary and recovery is expected to be rapid. The Pipeline route crosses surface waters, the potential disruption of which could impact on the hydro-morphology of the river channel depending on the timing of the construction works. However, the channel crossings have been designed so as to minimise the impact on the river channel and to ensure that flows are maintained. As such, there is unlikely to be a significant impact on downstream flows (Chapter 8 Soils, Groundwater and Surface Water).

Alterations to surface water flows may occur, however, as a result of land clearance, changes to topography, and development of temporary construction areas. It is unlikely that there will be any significant impacts on water flows due to changes in topography although surface water run-off may increase due to the removal of vegetation and compaction of bare soils. However, as streams are ephemeral, any changes in water flows are likely to be minimal and there are no identified surface water abstractors dependent upon surface water flows within the Affected Ecosystems. Further, the extent of clearance of natural habitat is small relative to the surrounding extent and so impacts on downstream water flows are likely to be insignificant.

\textsuperscript{13} A dewatering abstraction is the removal or draining of groundwater or surface water from an aquifer, riverbed, construction site, caisson, or mine shaft, by pumping or evaporation. Dewatering may be implemented before subsurface excavation to lower the water table.
Saltwater will be used for hydro-testing purposes although some freshwater will be required for construction activities such as the cleaning of plant and equipment, worker amenities, and in the use of construction materials such as concrete. All freshwater required during construction will be supplied from the Ministry of Defence well in Sukko. An estimated total volume of 37,000 m$^3$ of freshwater is required for the microtunneling process. In addition there will be a maximum usage of 25 m$^3$ per day for freshwater for general construction activities (domestic usages, wheel washing etc.) during peak periods. The water will be trucked to the construction areas from Sukko. There is a May – September (inclusive) exclusion period when water cannot be abstracted from the existing source at Sukko. Due to this restriction, a large quantity of water (up to 10,000 m$^3$) may need to be stored adjacent to the microtunnel construction site. A much smaller quantity of water (no more than 800 m$^3$) may need to be stored at the landfall facilities site.

Abstraction from the aquifer is managed through a licencing system which sets limits on abstraction volumes to ensure sustainable use. It is assumed that the licensed abstraction rate, including the seasonal exclusion period, has been set at a rate that will not cause the derogation, in terms of quality and quantity, of the aquifer resources, or of any other groundwater users within Sukko that utilise the same aquifer. Since all water required for Project activities will be managed through this licensing system and the rate of abstraction during construction will not exceed the licensed rate, Project impacts on the well-being of other water uses and the wider environment are likely to be negligible.

The overall impact magnitude is therefore considered negligible (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

**Impact Significance**

The overall significance of the Construction and Pre-Commissioning Phase of the Project on water (supply) is assessed as being **Not Significant** and water (supply) is not considered to be a priority service.

**Hazard Regulation**

The service considered in this assessment is the capacity of Affected Ecosystems to regulate natural hazards. The key beneficiaries include:

- Households and businesses located along the coastline and/or in areas that are vulnerable to flooding, erosion, and landslides;
- Recreational users who benefit from beaches along the coastline; and
- The Project itself which may be affected by flooding, erosion, and landslides.

The specific Project activities which could affect the hazard regulating services include:

- Site clearance and earthworks, particularly where these result in changes in topography and loss of vegetation;
- Impacts on the structural composition of Phaeozem soils which play an important role in water storage and flow regulation;
• Preparation of foundations may induce ground instability which could trigger mass movement of soils; and

• Dredging processes in the marine environment, particularly if this impacts upon coastal processes, and the effects of sea surges.

Receptor Sensitivity

The level of dependence on this service by the beneficiaries discussed above is assessed as low. The risk of surface water flooding and landslides to beneficiaries is low and vegetation within the Affected Ecosystems is considered to have a relatively limited role in regulating this risk relative to the surrounding habitat. Beneficiaries living in coastal areas, users of coastal beaches, and the Project itself are more dependent upon the regulation of coastal erosion and flooding, which could have significant impacts on health, operation, and well-being. However, the Affected Ecosystems again play a relatively small role in regulating this risk.

The role Affected Ecosystems currently play in regulating hazard risks could be replicated and improved through various engineered alternatives such as the construction of coastal flood defences, beach reclamation, creation of flood water attenuation ponds, or afforestation. Many of these approaches would, however, be expensive and/or take a long time to implement. It is therefore considered that there are few viable alternatives.

The Affected Ecosystems are considered to be moderately sensitive to change with respect to their ability to provide a hazard regulating service. Climate change is projected to lead to an increase in the frequency of extreme events including flooding and sea level rise over the next 50 years. Phaeozem soils are structurally prone to compaction and erosion which can reduce their ability to store and filter water and regulate flows. Subsequently, they are considered to have a low resilience to impacts, and would not readily return to their natural state within the Project’s lifetime.

Beneficiaries of this service (including the Project itself) are considered to be moderately vulnerable to any change in the provision of this service. While the ecosystems currently play a relatively limited role in regulating this hazard, small changes in ecosystem functioning can lead to changes in hazard risk which can lead to significant changes in well-being. For example, a change in vegetation cover in an area or an increase in intense rainfall events can lead to an increase in frequency of mudflows which can lead to structural damage and loss of crops. Larger towns (such as Anapa) are likely to have access to the resources necessary to adapt to changes in hazard risk, although there are a number of individual households and smaller communities which may be less able to adapt to changes in flood or erosion rates.

Overall the receptor sensitivity is therefore assessed as being moderate.

Impact Magnitude

Around 12.4 ha of natural habitat in the Affected Ecosystems will require some form of clearance during the Construction and Pre-Commissioning Phase. The removal of this area of vegetation (which binds soil particles together and protects the soil surface from wind and rain exposure) will expose bare soils to erosion and/or compaction caused by weather and the movement of heavy machinery and vehicles. The loss of Phaeozem soils, in particular, or
damage to their structural composition, could also impact on the ability of ecosystems to regulate water flows.

As such, it is likely that surface water run-off will increase which could in turn increase flood risk. However, the clearance of natural habitat is small relative to the service provision in the surrounding area and a qualitative flood risk assessment was undertaken within the catchment which found that impacts on surface water flows and flood risk are likely to be localised and are not likely to have a measurable impact on the well-being of any beneficiaries.

Construction of the stream crossing at the Graphova Gap could temporarily alter water flows during the works and could potentially result in flood flows being diverted onto the surrounding floodplain. Given the nature of the topography at the crossing site with relatively steep valley sides, any impacts on the flow regime are likely to be local to the crossing. The impacts of the construction works will be temporary and the watercourse will recover through natural processes. Further, it is proposed that any construction activities in the Graphova Gap will be undertaken during dry weather as far as is practicable, when the groundwater levels and surface water flows are expected to be lower.

Vegetation and soil also play a role in maintaining slope stability and preventing landslides, mud flows, and erosion. Earthmoving activities (including vegetation clearance, construction activities for the facilities, trenching activities for the Pipeline, and road access construction) may cause ground instability due to overloading of slopes and stockpiles of excess spoil waste. This could lead to slope collapse, gravitational slides (including landslides), mass soil movement, ground subsidence, and the formation of slope erosion features.

Depending on the size and nature of the soil loading and potential for subsequent ground movement, this could cause soil stability impacts that may be on-going over several years. Incidents of prolonged and heavy rainfall during the construction period could lead to mudflows which may be exacerbated by soil instability. This could potentially impact the Project itself and beneficiaries in the Local Area.

However, as described in Chapter 4 Analysis of Alternatives and Chapter 5 Project Description, the design and proposed construction methodology for the landfall facilities and Pipeline route have taken into consideration the potential geohazards, mitigating the risks as far as is practicable and the likelihood of the Project causing any landslide activity that could affect any beneficiaries is low.

Excavation and removal of marine sediment during nearshore dredging could potentially lead to alterations in coastal processes leading to changes in coastal flooding and erosion rates. However, it is considered extremely unlikely that dredging will result in a change in coastal erosion or flooding rates, as the dredging is taking place in water depths which should not change the height of incoming waves i.e. the wave height is not limited by the water depth. If the dredging site were closer to the shore, where the wave climate is significantly influenced by the bathymetry, then it is possible that increasing water depths (dredging) would increase wave heights and thus result in an increase in coastal erosion potential and/or flooding. However, even if this were the case, the change in depth would need to be significant before there was any attributable impact on the coast. As such, any impacts on coastal processes and beach formation / erosion rates or their users are likely to be negligible.
Taken together, it is unlikely that the Project will have any significant impact on the well-being of beneficiaries in terms of increased flood risk or through coastal erosion and flooding. The Project could, however, lead to a destabilisation of soils and land forms within the Affected Ecosystems. While this is unlikely to directly impact any identified beneficiaries, if there are periods of heavy and prolonged rains during construction, the measures taken to reduce impacts on soil stability could fail. This could potentially contribute to the formation of mudslides that may lead to disruption of Project activities, loss of agricultural land, and damage to buildings.

The likelihood of any impacts on beneficiaries’ well-being is likely to be low and any potential increase in risk of mud flows or slope instability would be felt periodically following heavy rains. Ecosystem functionality should be fully reversible following the construction period and any impacts in terms of increased instability would extend over several years as soil stability recovers through natural processes.

The impact magnitude is therefore considered to be low (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

**Impact Significance**

The overall significance of the impact of the Construction and Pre-Commissioning Phase on the well-being of people benefitting from hazard regulating services provided by Affected Ecosystems is assessed as being Low. Hazard regulation is therefore not considered to be a priority service during this Phase.

**Air Quality Regulation**

The service considered in this assessment is the capacity of Affected Ecosystems to regulate air quality. Due to the spatially diffuse nature of air and pollutant concentrations, the air quality regulation service cannot be directly linked to any particular ecosystem or area within it but rather is a cumulative service based on the interactions of multiple ecosystems.

While airborne pollutants can travel for long distances, those generated by Project activities are expected to disperse relatively quickly and to have a limited geographical extent. As such, the geographic scope of the service assessed within this section is the regulation of air quality within a 2 km radius of the Project Area, which is expected to be the greatest distance that any Project impacts could be felt (Chapter 9 Air Quality). The key beneficiaries include:

- Residential dwellings, a nursery, and school in Varvarovka;
- Residents and workers (particularly individuals with respiratory illnesses) in areas of Supsekh, Anapa, Rassvet and Gai Kodzor who benefit from clean air;
- The tourism industry (including the Shingari and Don resorts) which benefit from the influx of tourists seeking clean air; and
- People from across the region visiting the Local Area in order to benefit from the perceived health benefits of clean air (Ref. 17.24).
The Project activities which may impact provision of this service include:

- Clearance of vegetation;
- Emissions from offshore and nearshore vessels during pipeline installation;
- Emissions of pollutants from construction activities associated with the landfall section of the Project;
- Dust generation from construction traffic, land clearance, installation of the Project facilities, and installation of the Pipeline; and
- Emissions from road traffic during construction.

**Receptor Sensitivity**

Beneficiaries are highly dependent on the ability of ecosystems to regulate air quality as poor quality air, where pollutant thresholds are exceeded, is correlated with respiratory illness and death (Ref 17.56). The tourism industry is also dependent on good quality air for its marketing as a health resort. There are some activities which could feasibly be adopted to replace the air quality regulation service currently provided by Affected Ecosystems such as planting additional trees and green roofs (particularly in urban areas) to absorb more pollutants, or reducing pollutant emissions into the air quality regulatory system.

Based on the diffusion tube monitoring results, the ecosystem is considered to be of low vulnerability to changes in air quality, as vegetation cover is high and air quality thresholds within rural areas in the Local Area are not close to being exceeded. The vulnerability of receptors is considered to be moderate as there are significant resources within urban areas available for adapting to any changes in air quality, although there are some rural households and elderly or sick individuals who may be less able to adapt to a change in this service.

The overall receptor sensitivity is therefore considered to be moderate.

**Impact Magnitude**

Due to the relatively small amounts of pollutants released by the Project and the limited area of vegetation clearance required, the Project is not likely to significantly impact the ability of ecosystems to regulate air quality or lead to any negative impacts on the well-being of any beneficiaries of this service. The results of air quality modelling exercises found that there are unlikely to be any significant impacts on any identified beneficiaries (or any ecosystem functioning) in the area (Chapter 9 Air Quality).

The area of forest to be cleared (i.e. Shiblyak, Mesophilic forest, and Juniper woodland habitats) totals 7.6 ha (around 1.4% of the natural forested habitat in the Affected Ecosystems and a much lower percentage of the Local Area), which could lead to a reduction in the capacity of ecosystems to remove up to 114 tonnes of pollutants each year.

Due to the limited extent of this level of habitat clearance and the fact that the pollutant concentrations are generally significantly below threshold levels in rural areas, the magnitude of the impact on beneficiaries' well-being is likely to be negligible (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).
Impact Significance

In combination, the total impact significance on the well-being of people benefitting from the air quality regulation service provided by the Affected Ecosystems is considered to be **Not Significant** and air quality regulation is not identified as a priority service.

Water Quality Regulation

The service considered in this section is the capacity of Affected Ecosystems to regulate and maintain marine and fresh water quality. This includes water in Affected Ecosystems in the marine environment and freshwater resources used throughout the Shingar catchment. The key beneficiaries include:

- Local households and private companies within the Shingar catchment who abstract groundwater for drinking and industrial purposes (e.g. MOD and households with wells on properties);
- Users of St. Barbara’s Source for its spiritual / healing properties;
- Visitors, residents, and industry in Anapa SPNA dependent upon high water quality; and
- People working in the fishing industry who are in contact with marine water and those consuming the captured fish who benefit from the regulation of health risks.

Further beneficiaries of this service include tourists, recreational users, and the tourism industry who rely on good quality marine water for water sports, bathing, and scuba diving. In order to avoid double counting, impacts on these beneficiaries are assessed in Tourism and Recreation Values.

The specific Project activities that could affect the water quality regulating service include:

- An increase in pollution levels in surface and ground waters during construction activities due to soil disturbance, aerial deposition of dust generated by construction, leaks and spills from vehicles / plant, and waste generation;
- Clearance of terrestrial vegetation which absorbs pollutants and sediment from water resources;
- Disposal of contaminated water into the marine environment after use for hydro-testing, cleaning, and gauging the Pipeline;
- Seabed disturbance and release of sediments into the marine water column as a result of vessel movements, dredging, and Pipeline construction; and
- Reduction in the capacity of marine organisms to filter contaminants from the water due to loss of mussel beds and/or macrophyte strands.

Receptor Sensitivity

The dependence of beneficiaries on water quality is assessed as being high. Contamination of groundwater could have direct impacts on human health for those abstracting water from the environment, while contamination within the marine environment could also impact human health if marine water users come into direct contact with particular pollutants or if contaminants enter the food chain. Further, the Anapa Resort Town is a designated Sanitary Protection Area and the operation of the health industry and mineral water production is dependent on the continued supply of good quality water.
For both fresh and marine waters there are a number of alternatives to the water quality regulation service provided by the natural environment. These include planting new trees or creating wetlands in appropriate locations, chemically treating polluted waters, supporting the growth of biofiltering organisms within the marine environment, or reducing pollutant inputs from other sources. Since these activities are likely to incur relatively high costs, it is considered that there are some alternatives available.

Contaminant concentrations in fresh and saline resources in the Local Area exceed thresholds for a number of pollutants and marine sediments were found to have high concentrations of heavy metal contaminants (Chapter 8 Soils, Groundwater and Surface Water and Chapter 12 Marine Ecology). The capacity of these resources to assimilate any additional contamination is therefore likely to be limited. However, as noted in Section 17.6.6, actions by Black Sea States to restoring the ecological status of the Black Sea to a condition similar to that of the 1960s, has resulted in a decline in land-based sources of pollution and some improvements in ecological status. There are, nevertheless, still a number of external pressures which could impact the ability of ecosystems to regulate marine and fresh water quality such as climate change, rising water temperatures, and increasing development leading to habitat clearance and pollutant runoff. As such, fresh and saline water resources in the Affected Ecosystems are assessed as being of moderate sensitivity to change.

The sensitivity of beneficiaries of water quality regulating services provided by ecosystems within the Local Area is assessed as being moderate. While companies which abstract water directly (such as the Ministry of Defence) and the health industry within the Anapa Resort Town are likely to be able to access financial, technological, and legislative resources in order to adapt to any changes, groups such as individuals dependent on household wells (e.g. in Sukko) are less likely to be able to adapt to any change in this service.

The receptor sensitivity is therefore assessed as being moderate.

**Impact Magnitude**

Within the terrestrial environment, the Project could lead to contamination of surface and ground waters from leaks and spills during the construction period. The majority of leaks and spills are likely to be relatively small in volume and the construction drainage systems as outlined in Chapter 5 Project Description will collect and manage surface water runoff to reduce contamination risks. While ground and surface water quality could be locally affected, it is expected to recover through natural regulatory processes. Thus, the likely volumes of any spills are unlikely to significantly alter local pollutant concentrations or have significant lasting impacts on the ability of ecosystems to assimilate and regulate water quality.

Wastewater from domestic and industrial sources will be tankered off-site to an appropriate waste treatment facility and the risks associated with accidental release of oil, fuel, concrete and other pollutants will be controlled through appropriate storage, handling, and accident prevention procedures. Health complexes in Anapa Resort Town and St. Barbara’s Source are located upstream of the Project Area and are therefore unlikely to be impacted by any possible leaks or spills. As such the impact on beneficiaries is not likely to be significant.
Land clearance including the removal of vegetation, topsoil, hardstanding or existing structures may increase the potential for infiltration of precipitation through the soil, increasing leaching of soil contaminants to groundwater. Increased sediment entering the surface watercourses could result from land clearance, excavation works and erosional processes (particularly on soil stockpiles and on access roads close to gullies until road drainage is established). The eroded sediment may also have a high nutrient or contaminant content which can contribute to the enrichment and contamination of downstream waters. Impacts on surface water quality will typically be of short duration (i.e. during and immediately after a storm event) and for low concentrations of contaminants this will be off-set by natural regulatory processes in the Affected Ecosystems.

Disposal of hydrotest water and leaks or spills could release contaminants into the marine environment and lead to localised changes in water temperature and quality, although this is unlikely to significantly impact the ability of ecosystems to regulate water quality. The principal impact on the capacity of the environment to regulate water quality is likely to come from dredging activities and the resultant dispersal of sediments in the water column. High levels of Total Suspended Solids (TSS) can cause, inter alia, reduction in light penetration (leading to reduced photosynthesis), reduction in visual awareness, irritation of sensitive organs (gills), clogging of delicate filter feeding mechanisms, and the potential release of contaminants from disturbance of marine sediments.

Contaminants within the marine environment, such as heavy metals, bind onto sediment and can remain locked up indefinitely. As a result of the dredging process, any contaminants locked in the sediments could be dispersed into the water column which could pose a risk to human health for those using the marine environment for swimming and recreation. These contaminants could also be ingested by benthic organisms which filter seawater for food particles. As this group provides a valuable food source for many commercially important fish species (as well as some species such as sea snails being harvested directly), the contamination released through dredging could lead to uptake by marine life with potential negative impacts on human health in the area. Surveys of marine sediments in the Affected Ecosystems suggest that there are contaminants present which could be disturbed by dredging activities although the extent of disturbance of the seabed is likely to be limited due to the small spatial and temporal scale of the dredging activities required. The limited extent of disturbance and the fact that fish are likely to avoid areas of dredging suggests that the impact on the well-being of any beneficiaries is likely to be low (Chapter 15 Community Health, Safety and Security).

The impacts on well-being arising from changes in water quality regulation are therefore likely to be low. Spillages and sediment plumes may occur periodically throughout the construction
period and any impacts on beneficiaries are likely to be limited to this period. Impacts are of short duration (e.g. during and immediately after storm events), and the environment would be able to recover relatively rapidly through natural processes.

The overall impact on water quality regulating services is therefore assessed as being of low magnitude (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

**Impact Significance**

The impacts of the Construction and Pre-Commissioning Phase on the well-being of beneficiaries of the water quality regulation services provided by the Affected Ecosystems are considered to be of **Low** significance and water quality is not considered a priority service.

**Soil Quality Regulation**

The service considered in this section is the capacity of Affected Ecosystems to regulate and maintain soil quality. The key beneficiaries include:

- Landowners and the agriculture / viticulture industry within and around Affected Ecosystems (including consumers); and
- Workers who interact with soils and benefit from the regulation of health risks.

Further beneficiaries of this service include local residents and businesses who benefit from the soil's capacity to store water and reduce flood risk, as well as people dependent on surface water quality which can be impacted by changes in soils. In order to avoid double counting, impacts on these beneficiaries are assessed under Hazard Regulation and Water Quality Regulation sections respectively.¹⁴

The Project activities which may impact provision of this service include:

- Increase in concentration of contaminants which could exceed the capacity of soils to regulate quality through leaks and spills and deposition of dust and atmospheric pollutants generated during construction activities;
- Exposure and disturbance of existing areas of contaminated soil which are currently unknown to the Project;
- Increased susceptibility of soil to erosion through clearance of vegetation and excavation works;
- Loss of soils as a natural resource due to hardstanding / development relating to Project;
- Loss of nutrients and soil carbon due to soil excavation and removal of vegetation which contributes to soil composition; and

¹⁴ There is a significant degree of overlap with the soils service and other services such as crops, water quality, and hazard regulation. This is because soil regulation is part supporting service and part final service. In order to untangle the impacts and avoid double counting, any impacts on soils and soil productivity are considered in this section (not in the crops section) and any impacts on the ability of soils to regulate water flows or quality are discussed in the hazard regulation and water quality sections).
Degradation of soil, physical damage, and compaction through stockpiling of soils during construction.

Receptor Sensitivity

Agrifirm Kavkaz is dependent on the regulation of soil quality for the production of crops and value of uncultivated land as highly degraded soil, which is unable to regulate contaminants through natural processes, is likely to be of lower productivity and of lower value as a potential asset for sale. Workers are also dependent on the soil quality regulation service as disturbance of contaminated soil can lead to adverse health impacts. Taken together, the dependence on this service is considered to be high.

The regulation of soil quality played by ecosystems could potentially be replaced through the treatment of soils to get rid of contaminants, use of fertilisers (which could replace loss of nutrients or organic carbon), import of good quality soils from other regions, or through the purchase of good quality agricultural land elsewhere, although the costs of some of these measures may be high. As such, there are some alternatives considered available for this service.

The baseline data suggests that while soils are typically of good quality there are areas of elevated concentrations of particular substances which could be due to natural or manmade causes. Growing use of agrochemicals, motor vehicles, and air borne particles could increase pressure on soil quality regulation in future. While soils used for agricultural purpose are resilient to disturbance, Phaoezem soils are structurally prone to compaction or erosion, and to contamination through surface spills. As such, the sensitivity of the ecosystem to change is considered to be moderate.

Agrifirm Kavkaz is considered to be of moderate vulnerability to a change in provision of this ecosystem service as reductions in soil quality and the on-going ability of soil ecosystems to regulate contaminants could reduce the potential use and potential value of their landholdings. Workers are also likely to be vulnerable to changes in soil quality regulation although they are likely to be able to mitigate such changes through the adoption of adequate health and safety procedures and protective clothing which should be provided by their employers. Overall, the sensitivity of human receptors to changes in this service is considered to be moderate.

The overall receptor sensitivity is therefore considered moderate.

Impact Magnitude

The potential impact of the Project on the well-being of beneficiaries is considered to be high since the potential for contamination of soils which exceeds the assimilative capacity of ecosystems present could have lasting impacts on the quality of soil with subsequent impacts on human health and livelihoods.

Contamination of the soil may result through accidental leaks or spills during construction (e.g. during refuelling or waste handling). Potential pollutants include fuels, lubricants, cement, concrete, grout and slurry additives, and metals. Further risks of contamination arise through the potential for leakage during hydro-testing. Hydro-test water may contain high concentrations of suspended sediment including metal particulates. Other contaminants such as
hydrocarbons may also be present. Depending on the location of the leaks, this may permit test water to infiltrate through the soil, potentially influencing soil quality.

The Project could also disturb currently unidentified, localised pockets of soil contamination related to past land use or illegal dumping, although it is considered that the likelihood of encountering unidentified contamination is relatively low given the current land use.

Contaminated soil may affect workers through being inadvertently ingested or inhaled or through dermal contact and could have lasting impacts on the health of anyone exposed to soil contamination. Contamination of soil resources could also lead to reduced land values for Agrifirm Kavkaz if the long term productivity of soil is reduced. Further, if contamination from the Project impacts soil quality and the subsequent crops grown on that land are also contaminated, then there could potentially be human health risks due to the presence of contaminants in the food chain.

The removal of vegetation (which previously bound soil particles together and protected the soil surface from wind and rain exposure) will expose bare soils to erosion and/or compaction by the movement of heavy machinery and vehicles. The release of soil particles into surface watercourses and general migration down slopes could occur as a result of erosional processes. Earthworks and stockpiling of soils can lead to the mixing of different soil types, and also the changing of the soil structure. Such mixing can influence soil type and structure, which may influence ecosystems or agricultural usage. Similarly, mixing of excavated soil types can result in the contamination of previously clean soils by contaminated soils.

The impact of the Project on beneficiaries of the soil quality regulation service is long-term, with any contamination or impact on the structure of the soil occurring during the construction period likely to affect the current generation of users in terms of lower productivity, reduced ecosystem functioning, and increased health risk. Following the construction period, the ecosystem is expected to be able to recover from any impacts at natural recovery rates although for certain contaminants (such as heavy metals) or for significant structural damage, this could take significant periods of time. Impacts on soil quality are likely to be periodic, accidental events resulting from particular activities such as excavation works, vegetation clearance, and occasional spills or contamination events.

The overall impact magnitude is therefore considered moderate (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

**Impact Significance**

As such, the impact significance on the well-being of beneficiaries of the soil quality regulation service provided by Affected Ecosystems is therefore judged to be Moderate and soil quality regulation is identified as a priority service.
## Tourism and Recreation Values

The service considered in this section is the enjoyment of natural features in the Affected Ecosystems and activities provided by the natural environment or any livelihoods derived from such services. The key beneficiaries include:

- Users of the Mountains of the Caucasus trail and horse riding trails;
- People using Sukko beach and the surrounding marine environment for activities such as sunbathing, swimming, yachting, scuba diving etc.;
- Visitors to the Shingari and Don holiday complexes; and
- Tourism operators and their employees operating in the Local Area who may depend on tourism for their livelihoods including dive operators, horse riding operations, and holiday complexes.

The specific Project activities that could affect these services during the Construction and Pre-Commissioning Phase include:

- Noise and visual disturbance during construction activities;
- Reduced access to sites used for recreation such as horse riding trails or areas of marine space used for yachting and swimming;
- Reductions in marine water quality which could impact on bathing activities, water sports, and scuba diving etc.;
- Impacts on marine ecology such as loss of mussels and other benthic species which contribute to beach formation or disturbance to species of importance for scuba diving; and
- Impacts on beach formation due to dredging activities and changes in coastal erosion and deposition rates (impacts on coastal processes are assessed under Hazard Regulation earlier in this section).

### Receptor Sensitivity

Tourism makes an important contribution to the economy of the Local Area, with up to 4.5 million visitors travelling to ART each year. The designation of Anapa as a resort town recognises its national importance as a place for tourism. Further, a number of smaller scale tourist organisations are dependent on income from tourists visiting ecosystems in the area including the owners of the Shingari and Don complexes. As such, dependency on this service is considered to be high and, while there are alternative tourist destinations, few are considered to offer equivalent benefits as the ART area.

Many of the tourism and recreation opportunities provided within the Local Area are ecosystem based, including hiking along the Mountains of Caucasus trail, horse riding, bathing, beach-based recreation, water sports, and scuba diving. As such, it is considered that tourism is highly sensitive to changes in the quality of the natural environment in terms of both levels of enjoyment (by visitors and recreationalists) and income and employment generated by visitors to ART.

The receptor sensitivity for tourism and recreation services is therefore considered to be high.
Impact Magnitude

There are four potential Project impacts which could affect the ability of beneficiaries to enjoy recreation or derive livelihoods from this service: noise and visual disturbance; loss of access to recreational resources; declines in water quality; and impacts on marine ecology.

The presence of pipe laying vessels and other construction vessels may give rise to adverse visual and noise impacts on recreational users of beaches, hiking trails, and the sea. This could temporarily reduce the enjoyment of the Affected Ecosystems by visitors and could potentially reduce customer numbers for certain businesses leading to impacts on livelihoods.

The beneficiaries of most concern with respect to these impacts are visitors to, and owners of, the Shingari and Don holiday complexes, as well as visitors to the Sukko public beach. Consultation with owners of the Shingari resort revealed that they are particularly concerned about the impacts of construction activities on noise and sea water quality as swimming and other water based activities form a key component of the leisure opportunities offered at the resort.

As set out in Chapter 10 Noise and Vibration, noise modelling suggests there will be a residual impact of Low significance on the Shingari and Don resorts during Pre-Commissioning associated with cleaning, gauging, and drying of the pipelines. The impact is temporary and is expected to last for around 20 days. Chapter 13 Landscape and Visual Assessment identifies a moderate adverse residual visual impact on these beneficiaries during construction. The visual impact assessment states that the impact will be temporary and short term as the marine construction vessels, and in particular the pipe laying vessel, will only be highly visible to visitors at Shingari and Don holiday complexes for a few days (or a week at most) during the construction of each pipeline. The four pipelines are to be laid as quickly as possible over a period of approximately 15 months commencing in Q1 2015. Visual disturbance will be likely to occur on a single occasion during the main summer peak period when occupancy of the holiday complexes would be at its highest. Following construction the impact will cease. Disturbance from the Project will therefore be temporary and is unlikely to prevent anybody from undertaking recreational activities in the Affected Ecosystems. As such, it is considered that the magnitude of impact on the Shingari and Don holiday complexes will be low.

While the magnitude of any impact is considered likely to be low, visual impacts on beach users could potentially impact on the business revenues of the Shingari and Don Holiday complexes if guests are deterred from staying. This will depend on the timing of the construction work, particularly in the nearshore section closest to the holiday complexes, and the perceptions and reactions of guests. Impacts could therefore last beyond the Construction and Pre-Commissioning Phase of the Project if guests do not return or provide negative feedback to others.

For users of Sukko beach, marine construction vessels, and in particular the pipe laying vessel, will be highly visible for a few days (or a week at most) during the construction of each pipeline. The four pipelines are to be laid as quickly as possible over a period of approximately 15 months commencing in Q1 2015. As such, the impact will be likely to occur on a single occasion during the main summer peak period, when usage of the beach would be highest. Following construction, the impact will cease and beach users will not experience any impacts in
Chapter 17 Ecosystem Services

relation to the operation of the Pipeline. As such, amenity-related visual impacts are temporary and unlikely to compromise beach users’ ability to enjoy recreational activities such as swimming, playing, sunbathing etc. Therefore, any impacts on the well-being of beneficiaries are likely to be of low magnitude.

There is a potentially significant adverse visual impact on users of the Mountain of the Caucasus Trail which runs along the top of the cliff and affords users clear views out to sea. However, these impacts are likely to be temporary and aside from a changed visual outlook, there will be no other impact on users’ enjoyment of, or access to, the trail. The extent of the impacts, in terms of the number of people affected, would be low given the relatively low usage of the trail.

In addition to noise and visual disturbance, the Project may restrict access to certain recreational activities in the marine and terrestrial Affected Ecosystems. In the marine environment, safety exclusion zones will be created in order to avoid impacts on recreational water users. While there could potentially be an adverse impact on sailing activities, it is considered that recreational sailors will not be impacted by the Project given their ability to easily navigate around the vessel spread during construction of the nearshore and offshore sections. There is one dive site (the Gordipiya barge, a sunken wooden shipwreck which has become an artificial reef) located close to the nearshore section of the Project although the site lies outside of the safety exclusion zone and access will not be restricted (Figure 17.13).

In the terrestrial environment, impacts on horse riding operations could be more significant as, in addition to visual disturbance, the operator may lose access to horse riding trails (or at least parts of them) during the Construction Phase which could impact on their business. While the exact details of the riding route have not yet been identified, if it crosses the Pipeline route, the business will not be able to use that route during the period of construction of the Pipeline and the owner will need to find a suitable replacement riding route. However, until the current route is confirmed, it is not possible to assess what impact the Project may have on this business.

A further potential impact is a decline in marine water quality due to sediment dispersal during the dredging process which could potentially impact on the Shingari and Don resorts, recreational water users, and scuba diving operations. The results of sediment modelling studies undertaken for the ESIA found that sediment is dispersed from each proposed dredging and disposal operation, a process that lasts 1.3 days per pipeline operation (Appendix 12.2 Sediment Dispersion Study).

Dredging activity could potentially affect the quality of the water at the beach in front of the Shingari complex for short periods of time under certain conditions depending on the prevailing currents and the level of sediment suspension in the water. However, modelling indicates that even in a worst case scenario, any sediment plume impact on the beach will be minor and concentrated in one area for 3 to 5 days per pipeline. Taking these factors into account, the magnitude of impact on visitors to and owners of the resort are likely to be low.

There is a potential risk to scuba dive operators if sediment dispersal reduces seawater quality and clarity at diving spots used by diving tour operator businesses off the coast from Sukko. However, the extent of sediment blooms are likely to be small and of short duration (a matter of days). Alternative dive sites are also available and, as such, the significance of any impacts on divers and dive operators are likely to be low and easily avoidable.
The quality of diving conditions is also dependent upon the range of marine species present although Chapter 12 Marine Ecology indicates the significance of Project impacts upon marine species is generally low and temporary. As such the impact on the well-being of divers is not likely to be significant. Impacts on mussel and other benthic species are likely to be limited and there is unlikely to be any resulting change in beach formation rates.

Taken together, the impacts of the Project on the well-being of beneficiaries of the tourism and recreation services are likely to be low, as it is unlikely that any activities or uses will be prevented. However, there is potential for some loss of well-being and livelihoods for visitors to and owners of the Shingari and Don holiday complexes, the horse riding operator in Varvarovka, visitors to Sukko beach, and users of the hiking trail. The impacts are expected to occur for short periods during the Construction and Pre-Commissioning Phase whereafter the Affected Ecosystems are expected to recover completely in a short period of time (as impacts are primarily visual disturbance and reduced access). The beneficiaries will be affected periodically by discrete activities during the Construction and Pre-Commissioning Phase.

The overall impact magnitude is therefore considered to be low (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

**Impact Significance**

The overall significance of the impact of the Construction and Pre-Commissioning Phase is considered to be **Moderate** and tourism and recreation services are identified as a priority service.
LOCATION OF DIVE SITE CLOSEST TO THE SAFETY EXCLUSION ZONE OF THE PROJECT

- Approximate 3km offshore construction safety exclusion zone
- Shipwreck diving site (plotted based on approximate location coordinates N 44°46' E 37°22')
- Russian Sector of South Stream Offshore Pipeline
- Proposed landfall section pipelines
- Landfall facilities
- Proposed microtunnels
- Right-of-Way
- Proposed offshore pipelines
- Microtunnel entry shaft
- Microtunnel exit pit
- United Gas Supply System
- Russkaya compressor station
- United Gas Supply System pipelines
- Isobaths
Cultural and Spiritual Values

The services considered in this section are the cultural and spiritual values provided by, or dependent upon, Affected Ecosystems. The key beneficiaries of this service are therefore:

- Local and regional visitors to the Varvarovka cemetery; and
- Local residents and visitors who benefit from the cultural and aesthetic qualities of the landscape, its history and identity as an area of agricultural production, and its situation adjacent to the Black Sea.

Additional beneficiaries of this service include visitors to memorials and religious sites such as St. Barbara's Source and the festival at the khachkar, although there are no identified Project activities which may impact on the ability of beneficiaries to access or use these services.

Wider beneficiaries could also include the national and global scientific community who may be interested in terrestrial and marine archaeological sites. Chapter 16 Cultural Heritage identified a number of archaeological resources which could be impacted by the Project, including: a burial mound, a submerged aircraft wing, a ceramic amphora, and a wooden shipwreck.

However, the sites do not presently have any strong or special significance for any particular community or cultural group for social, cultural, or spiritual reasons. The sites of cultural or archaeological heritage identified are not sacred sites and are not the focus of traditional beliefs and ceremonies, mainstream religious practices, secular pilgrimage, or cultural identity. As such, the value of the sites that may be disturbed is considered to be principally historic and scientific, rather than of aesthetic, community / social or spiritual value for present or future generations. A full discussion of the Project's impact on these sites is provided in Chapter 16 Cultural Heritage.

Therefore, the assessment focuses on potential impacts on visitors to the Varvarovka cemetery and residents of the Local Area who value the cultural and aesthetic nature of the landscape.

The Project activities which may impact provision of this service include:

- Damage to the environmental setting of the Local Area and particular sites through vegetation clearance, noise pollution, and visual disturbance; and
- Loss of tranquility and disturbance to cemetery visitors through increased construction related traffic and visual disturbance.

Receptor Sensitivity

While local and regional populations are not likely to be dependent on cultural services for their livelihoods or income, they may nevertheless value them and derive spiritual and cultural gratification. Within the area the agricultural and coastal landscape has an important aesthetic value and plays a role in the cultural identity of local communities. Further, relatives of those buried in the Varvarovka cemetery are likely to be highly dependent on this service in terms of their ability to remember and pay respects to the deceased.

The aesthetic and cultural identity of a landscape and the populations living within it cannot be replaced through construction or engineering. Likewise, there are no alternative sites for visitors to the Varvarovka cemetery where they can visit their deceased relatives and, while it may be
possible to relocate the cemetery, it would entail significant social and economic costs. As such, it is considered that there are no alternatives to this service.

The environmental setting of cultural sites is considered of low sensitivity to change since habitat is well replicated in the area and, although ecosystems may be vulnerable to direct impacts such as land and vegetation clearance, they are not likely to be particularly vulnerable to more indirect changes such as climate change, population growth, changing water availability or temperature etc.

Local populations are likely to be sensitive to significant changes in the nature of the landscape although will be less sensitive to small changes due to the extent of natural habitat and its ability to absorb visual impacts. Visitors to the cemetery, on the other hand are likely to be highly sensitive to change spiritual services are strongly linked to the nature of the environmental setting.

In sum, the receptor sensitivity for cultural and spiritual services is considered to be high.

**Impact Magnitude**

Any development which requires vegetation clearance within a landscape with cultural and aesthetic value to local populations will have an impact on the aesthetics and identity of the area. However, the relatively small extent of natural habitat loss and productive agricultural land which will be cleared by the Project (Table 17.13 and Table 17.14), together with the use of microtunneling which means that most of the cleared land can be replanted following construction, mean that it is unlikely the Project will significantly change the character of the landscape or the nature of the Local Area as a productive agricultural region (Chapter 13 Landscape and Visual Assessment). As such, the Project is unlikely to have a significant impact on the cultural value of the landscape and is unlikely to lead to a significant change in the well-being of any beneficiaries of this service.

In addition to general landscape impacts, there may be a localised increase in noise and visual intrusion to the environment surrounding the Russian Orthodox and Armenian cemetery at Varvarovka. Visitors to the cemetery are likely to value and also place importance on the surrounding environment, and any disturbance of tranquillity to users could have an impact on well-being during construction activities.

**Chapter 10 Noise and Vibration** finds the impacts in terms of noise and vibration on the cemetery to be negligible, however, **Chapter 13 Landscape and Visual Assessment** finds an impact of moderate magnitude due to views of the construction activities and use of the access road along the northern and eastern boundaries of the cemetery. While there is likely to be a degree of visual intrusion into the environment surrounding the cemetery it will be temporary and the extent of disturbance is not likely to prevent visitors from using the site or being able to pay their respects.

Impacts on the well-being of beneficiaries of cultural services are therefore likely to be low and any disturbance is likely to be felt periodically throughout the duration of the Construction period. The ecosystems themselves are likely to be able recover naturally within the short term from such disturbance.
In sum, the impact magnitude for cultural and spiritual services is considered to be low (refer to Appendix 17.3 for the scoring against each of the impact magnitude criteria).

Impact Significance

In combination, the total impact significance on the cultural and spiritual values ecosystem service is therefore judged to be Moderate and cultural and spiritual services are identified as a priority service.

Wild Species Diversity

The service considered in this section is the diversity of locally, regionally, nationally, or globally important species which live within, or are dependent upon, Affected Ecosystems. The beneficiaries include:

- Any communities within the Local Area, wider region, nation, or global area who value and appreciate the existence and diversity of species living within or dependent upon Affected Ecosystems.

The Project activities which may impact provision of this service include:

- Loss and fragmentation of terrestrial habitat resulting from vegetation clearance during soil stripping and land clearance;
- Killing, injury, and disturbance of individual terrestrial species during site preparation and construction as well as noise and vibration emissions from vehicles, plant, and construction activities;
- Introduction of non-native species to the terrestrial environment;
- Impacts on aquatic life through vessel and welding wastes, cooling water discharge, proximity of vessels, and use of lighting;
- Impacts on benthic communities from seabed disturbing activities including surveys and inspections, obstacle removal ("pre-sweeping"), dredging, pipe-laying, post-lay trenching, rock placement / seabed intervention, and anchoring;
- Disturbance to seabirds through vessel movements during mobilisation, surveying and pipe-laying activities, displacement or loss of prey in the nearshore area, and mortality due to bird strikes on highly illuminated offshore installations; and
- Disturbance to marine mammals through surveying and pipe-laying activities, cooling water discharges, displacement of food resources, noise and collisions from vessel movements and use of dynamic positioning.

Receptor Sensitivity

Beneficiaries of wild species diversity (i.e. those who value the existence of wild species) are considered to be of moderate dependence on the service. While there were no beneficiaries identified as being dependent on any species for livelihoods or income, the high level of concern about impacts on wild species raised during consultation, together with the presence of critically
endangered species of global conservation significance, suggest that this is an important service to beneficiaries and one on which welfare depends to a moderate extent.

The ecological role of a particular species could potentially be replaced by others although the existence value of that species cannot. Therefore, there are no replacements available to individual species. If a species is lost from an area it could be reintroduced from other areas although there are significant costs associated with such processes and a successful reintroduction can be difficult to achieve.

Due to the identification of Critical Habitat within the Affected Ecosystems and presence of the critically endangered Nikolski’s tortoise in the terrestrial environment the ecosystem sensitivity is considered to be high, although the receptor sensitivity is considered low due to the widespread national and international financial and legislative resources available to adapt to any changes.

In sum, the receptor sensitivity for the wild species diversity service is considered to be high.

**Impact Magnitude**

There are a total of ten habitat types falling within the terrestrial Affected Ecosystems, five of which will require an area of habitat loss. Table 17.14 lists these habitats and the area of each habitat falling within the Affected Ecosystems which will be cleared or which have already been cleared to facilitate the geotechnical surveys undertaken in 2012 ([Chapter 11 Terrestrial Ecology](#)).

*Modified habitats

As set out in Table 17.14, the Project requires clearance of Critical Habitat (Mesophilic forest and Tomillyar) and habitat which has important local values (Juniper woodlands). However, the extent of habitat clearance relative to the surrounding area is relatively small scale and is unlikely to have long term impacts on the nature or population viability of the habitats to be cleared. As such, the impact on beneficiaries is likely to be low.

In the absence of appropriate design controls, there is the potential for the introduction of invasive fauna and flora during construction. Although of a relatively low probability, introduction of invasive species has the potential to significantly alter the ecology of natural habitats and affect their overall integrity in the long term.

With regards to fauna species, the greatest impacts within the terrestrial Affected Ecosystems are likely to occur due to the removal of mesophilic and shiblyak woodland which provide habitats for nesting birds and reptiles. Of particular concern are potential impacts on Nikolski’s tortoise which is known to occur within the Affected Ecosystems.

These habitats, together with juniper woodland and secondary steppified meadow, are of particular importance to the tortoise during the active period for foraging, shelter, breeding and hibernation and have the potential to support significant numbers of Nikolski’s tortoise. Local populations of this species are of important conservation significance to this species and construction activities may lead to disturbance and direct mortality of the species. Further impacts on this species could occur through loss and fragmentation of habitat (due to road construction), soil excavation which may impact hibernating and reproduction, or direct mortality through construction activities and are likely to be of significance to the global conservation community.

The marine Affected Ecosystems lie within Tier 2 critical habitat, which was identified according to IFC criteria for endangered, migratory, and congregatory species for certain pelagic fish, seabirds, and cetaceans. While the Project is unlikely to have any significant impact on this habitat, there may be some disturbance to particular species during construction activities. In particular, vessel movements during mobilisation, surveying and pipe-laying activities have the potential to temporarily disturb marine mammals which are of value to people in the region. However, these are highly mobile animals with acute sensory perception and are generally able to avoid areas of disturbance and only a few individuals are likely to be affected, if any. As such, there are unlikely to be any threats to the population of cetacean species or any significant impacts on the well-being of beneficiaries who value these species.
Chapter 17 Ecosystem Services

There may also be some temporary disturbance to fish and bird species although they are likely to be of low significance. The tub gurnard, which may be of importance in the Local Area, faces some risk due to potential loss of food and habitat in excavated areas, however, there are unlikely to be any significant impacts on populations or their beneficiaries.

Taken together, the small extent of habitat required for the Project and the nature of the construction activities are unlikely to have a significant impact on the long term viability of populations of any of the species in the area. As such the impact on well-being is expected to be low. However, the length of impact on beneficiaries of the service (such as through clearance of valued habitat) is likely to extend across the current human generation who value species diversity in the affected area.

Populations are likely to recover from any noise, disturbance, or collision damage following the construction period, however, loss of terrestrial habitat or introduction of any species which become successfully established could have longer lasting impacts on the ability of species to feed and reproduce, which could have long term impacts on population structures. The risks and disturbance to species (and therefore the impact on beneficiaries) are likely to occur regularly throughout the construction period.

In sum, the impact magnitude on the wild species service is considered to be moderate (see Appendix 17.3 for the scoring against each of the impact magnitude criteria).

Impact Significance

In combination, the total impact significance on the wild species diversity ecosystem service is therefore judged to be High and is identified as a priority service.

17.7.2.3 Mitigation and Monitoring

Based on the results of the impact assessment (see Appendix 17.3 for a detailed summary of the scoring assigned to each ecosystem service), five ecosystem services were identified as priority services which are likely to be significantly impacted during the Construction and Pre-Commissioning Phases of the Project and which will require further mitigation:

- Crops;
- Soil quality regulation;
- Tourism and recreation values;
- Cultural and spiritual values; and
- Wild species diversity.

In accordance with Good International Industry Practice, the Project will strive to avoid and then to minimise impacts as far as possible through design before undertaking mitigation measures. Design controls aimed at achieving this goal are summarised in the description of relevant Project design controls set out in Chapter 5 Project Description.

Where impacts cannot be avoided through design, appropriate mitigation measures for each of the adverse environmental and social impacts identified are discussed in detail in the relevant technical chapters. For the priority services identified, the measures implemented by the Project
have the additional goal of maintaining (or restoring where they have been damaged or degraded) the value and functionality of these services for beneficiaries over the short and long-term.

Due to the cross-cutting nature of ecosystem services, mitigation of impacts on these services will be captured under a range of Construction Management Plans (CMPs) in the Health, Safety, Security and Environmental Integrated Management System (Chapter 22 Environmental and Social Management).

**General Mitigation Measures**

A number of General Mitigation measures will be adopted by South Stream to address adverse impacts where appropriate. These include:

- A Grievance Procedure which will be implemented by South Stream Transport in partnership with its contractors and will ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way, following a standard procedure of investigation, analysis, and resolution. It will also ensure that resolutions are documented and communicated to the appropriate stakeholders;

- A Compensation Management Framework to guide the evaluation and determination of compensation measures. The Compensation Management Framework will capture the process and requirements for assessing compensation claims and implementing compensation measures;

- A Livelihood Restoration Framework to provide for the possibility that livelihood impacts do occur. This Framework will define the process that will be undertaken to identify the need for specific livelihood restoration measures, and the development of these measures in consultation with affected stakeholders and relevant local agencies. The overall goal will be to ensure that affected livelihoods are restored, at minimum, to pre-impact levels;

- On-going Stakeholder Consultation throughout the Construction and Pre-Commissioning Phase. These engagement activities will be designed to facilitate dialogue with relevant stakeholders, including those potentially affected by the Project, or who are concerned about or interested in the Project. These activities will allow potential impacts, issues and concerns to be identified early on and addressed in an expedient manner. These activities will also inform stakeholders of upcoming construction activities, as well as Project Activities that have been completed, and provide advance warning of any anticipated changes; and

- A Community Investment Plan to guide community investment initiatives and opportunities for the Project.

Further details on these measures are set out in Chapter 14 Socio-Economics.

In addition to applying these General Mitigation measures where appropriate, a number of specific measures will be adopted to address impacts on ecosystem services and their beneficiaries where required. The full range of mitigation measures for each priority service is set out below.
Crops

The Project was identified as having an impact of moderate significance on provision and use of this service due to potential economic displacement of workers employed by Agrifirm Kavkaz.

Measures to avoid impacts on land use and vegetation clearance are set out in Chapter 5 Project Description. However, it is not possible to avoid all impacts on this service as an area of productive agricultural land will need to be cleared to allow construction of the Project.

While it is unlikely that the clearance of agricultural land will lead to any on-going displacement of workers, there could potentially be limited, temporary displacement during construction activities. As such, the General Measures at the start of this section, Section 17.7.2.3, will apply as appropriate.

In addition, after construction, all land that is not required for permanent above ground infrastructure in the Operational Phase will be reinstated to a state as near to the original condition as possible or to a form in keeping with the surrounding topography where this is not precluded by risk to integrity of the Pipeline or erosion considerations. All necessary actions will be applied to ensure that reinstated land can function, at minimum, as productively as that prior to land acquisition.

Residual Impact

While it is unlikely that there will be any displacement of workers, the Grievance Procedure, Livelihood Restoration Framework, Land Acquisition Policy, and Compensation Management Framework are in place to ensure that there are no lasting impacts on the wellbeing of any workers if displacement does occur. These policies will compensate for any impacts on livelihoods.

The small extent of agricultural land clearance together with the development and implementation of a LRF mean that there are unlikely to be any significant residual impacts on workers employed by Agrifirm Kavkaz, although it is not certain at this stage. As such, while the impact magnitude with mitigation in place is likely to be reduced to negligible, it is considered that the overall residual impact is of Low significance.

Soil Quality Regulation

The impact on soil quality was assessed as being of moderate significance. The primary impacts with respect to beneficiaries are likely to be in terms of potential contamination of soils or disturbance of existing areas of contamination which could lead to human health risks, and structural damage to soils which could lead to lower soil productivity and impairment of natural ecosystem functioning. Mitigation measures for these impacts are set out below.

Human Health Risk

The main risks of soil contamination can be avoided by adopting the mitigation measures set out in Chapter 8 Soils, Groundwater and Surface Water. While it is unlikely that contamination risks can be avoided completely, development of a Spill Prevention and Response Plan for early identification and disposal of contamination should minimise any remaining risk.
In addition, in order to reduce the risk of disturbing existing areas of contamination a contingency plan will be developed in the ESMP to deal with encountering soil contamination not identified during the pre-construction studies. In the event that previously unidentified contamination is observed during construction, the plan will set out that works in the affected area will cease and appropriate mitigation measures will be designed.

Following these mitigation measures there may be potential risks to workers on the Project who are in contact with soil if contamination is identified. Workers will therefore be given access to the necessary safety equipment as well as full health and safety training in accordance with the Health and Safety Plan.

*Structural Damage to Soils*

A number of measures are also set out in Chapter 8 Soils, Groundwater and Surface Water to minimise structural impacts on soils including careful management of the topsoil to be displaced during construction as well as replanting of native vegetation which will help to maintain the structural and ecological integrity of the soil.

*Residual Impact*

With the mitigation measures set out above, the risks to the health of workers and structural composition of the soil should be reduced to negligible. As such, the magnitude of impacts with mitigation is considered to be negligible and the overall residual impact is therefore *Not Significant*.

*Tourism and Recreational Values*

The impact significance of the Project on tourism and recreation values was assessed as moderate. The principal impacts on beneficiaries are likely to be in terms of disruption to users and owners of the Shingari and Don resorts due to visual impact; disruption to users of Sukko beach and the surrounding marine environment; and potential disruption of horse riding operations.

Design controls are set out in Chapter 5 Project Description to avoid impacts on this service although it is unlikely that adverse impacts on beneficiaries can be avoided altogether. Measures to minimise unavoidable impacts and compensate beneficiaries where necessary are set out below.

*Disturbance to Shingari and Don Resorts*

The General Measures at the start of this section, Section 17.7.2.3, will apply as appropriate. In addition:

- Plans indicating the Pipeline route and construction phase vessel spread along with timing of construction activities will be provided to the relevant authorities for distribution to local businesses as appropriate, including Shingari and Don holiday complexes;

- For visual impacts that have not been avoided through design controls, Chapter 13 Landscape and Visual has set out mitigation measures to mitigate visual impacts. Specifically, to mitigate impacts on recreational visitors to the seashore, including the public
beaches at Sukko and Anapa, and the private beach at the Shingari and Don holiday complexes, mitigation includes: phasing construction where practicable; avoidance of nighttime construction activities as far as practicable; and directional shielding for lighting on vessels, other than navigational lights on vessels; and

- **Chapter 12 Marine Ecology** sets out measures to prevent sedimentation impacts on recreational water users along the coast line.

**Disturbance to Users of Sukko Beach and the Surrounding Marine Environment**

The General Measures at the start of this section, Section 17.7.2.3, will apply as appropriate. Specific to recreational beach users, the Project will provide regular updates to beach users regarding construction activities and schedule, both on land and at sea. Updates and information provided to beach users will also include information about how interested parties can contact South Stream Transport with questions, concerns or complaints.

As set out in respect to the potential for reduced business revenues on Shingari and Don holiday complexes and the Anapa Resort Town tourism sector, **Chapter 13 Landscape and Visual** has set out mitigation measures to mitigate visual impacts. Likewise, **Chapter 12 Marine Ecology** also sets out measures to prevent sedimentation impacts on recreational water users along the coast line.

**Impacts on Horse Riding Operations**

The General Measures at the start of this section, Section 17.7.2.3, will apply as appropriate. In addition:

- The Project will work with the Varvarovka Horse Riding Business to undertake further investigation to check the horse riding route prior to construction to understand whether or not there may be an impact on the horse riding business if the route is not usable during the construction period and, if so, whether mitigation is required; and

- If access to all or part of the horse riding route is restricted or severed by the Project, South Stream Transport will work with the business owner to identify a suitable alternative. Whether or not an alternative can be found, the Compensation Management Framework and Livelihood Restoration Framework will also apply in the event that impacts on business revenues are evident. South Stream Transport will also engage with the stakeholder prior to and throughout the Construction and Pre-Commissioning Phase to ensure that the stakeholder is informed of Project activities and restrictions, and to understand any concerns the stakeholder may have. The Grievance Procedure will also apply to any complaints related to horse riding and related business impacts.

**Residual Impact**

The mitigation measures set out above are expected to reduce the significance of any impacts on the Don and Shingari resorts to negligible as financial compensation will be provided if necessary to ensure there is no loss of livelihoods.

For users of Sukko beach and the surrounding marine environment the mitigation measures listed above are unlikely to entirely eliminate potential impacts on beneficiaries as there will be
some level of temporary visual disruption. While they cannot be eliminated, the impacts are unlikely to have a significant lasting effect on the ability of any beneficiaries to enjoy recreational services in the area or impact on livelihoods derived or dependent on this service.

The measures set out to address impacts on the horse riding operation (including the Livelihood Restoration Framework) should reduce the magnitude of the impact.

As such, with the proposed mitigation measures in place the magnitude of impacts is expected to be negligible and the residual impact significance is expected to be **Low**.

**Cultural and Spiritual Values**

The impact on this service was assessed as moderate significance, primarily due to loss of tranquillity and disturbance to users of the Varvarovka cemetery.

The General Measures at the start of this section, Section 17.7.2.3, will apply as appropriate. Further mitigation measures to address this are set out in Chapter 13 Landscape and Visual and Chapter 16 Cultural Heritage including re-routing the proposed access road in proximity to the cemetery in order to minimise the impact on visual amenity and landscape character, and planting of vegetation to act as screening.

The implementation of this mitigation should reduce the impact on well-being to negligible and the impact significance to **Low**.

**Wild Species Diversity**

The impact significance of the Project on wild species diversity was assessed as high. The principal impacts on beneficiaries of terrestrial wild species are likely to be in terms of habitat clearance, in particular loss of Critical Habitat and juniper woodlands of important local value; the risk of introduction of alien invasive species which could disrupt populations of existing species and disrupt the balance of ecosystem functioning; and disturbance to an important population of the critically endangered Nikolski’s tortoise. With regards to beneficiaries of marine wild species, the principal impact is likely to be disturbance to charismatic cetacean species in the marine environment.

**Chapter 5 Project Description** sets out a range of design control measures to avoid impacts on this service. Since some level of impact is unavoidable, additional measures are set out in Chapter 11 Terrestrial Ecology and Chapter 12 Marine Ecology. These chapters set out a detailed mitigation approach which comprises general mitigation measures for addressing impacts on the terrestrial environment, a herpetile mitigation strategy for addressing impacts on herpetile species including Nikolski’s tortoise, a Biodiversity Action Plan (BAP) for ensuring net gain in critical habitat, and measures for addressing impacts on the marine environment.

**Impacts on Terrestrial Species and their Beneficiaries**

The general mitigation measures will include provision for an Ecological Clerk of Works (ECoW), training of construction personnel, and implementation of a CMP which will minimise the risk of introduction of invasive species.
The Herpetile Mitigation Strategy will cover the construction period and will detail the measures to be employed to protect key ecological receptors such as the Nikolski’s tortoise, particularly during initial site clearance works. One of the main risks to this species is harvesting for use in the pet trade, for medicinal purposes, and for food (Ref 17.53). All such, all workers on site will receive education and training with regards to identification of this species and the importance of protecting individuals and avoiding any unnecessary disturbance.

While these measures should reduce the residual impacts on the species to low, given the sensitivity of the receptor, the conservation community may still be concerned about the impacts of the Project. Given this, the Project will further mitigate any potential impacts on the species and its beneficiaries through engaging with local stakeholders (e.g. the Utrish reserve and universities researching this species) and support research and conservation efforts directed at the species.

The Project’s mitigation strategy will be described in a BAP and will be designed to achieve net gains of those biodiversity values for which the critical habitat was designated. Management and monitoring requirements for an appropriate length of time will also be specified.

Since particular habitats such as juniper woodlands have important local value and the habitat mosaic provides important ecosystem services in addition to its role in supporting wild species diversity (such as enabling soil, water, and air quality regulation; cultural / aesthetic values; hazard regulation; provision of wild foods etc.), the BAP will take such considerations into account when designing any habitat restoration measures.

**Impacts on Marine Species and their Beneficiaries**

Within the marine environment, measures are set out in Chapter 12 Marine Ecology to reduce disturbance to cetacean species. A monitoring programme, particularly for fish, birds and mammals, will be appropriately designed to meet research objectives that enhance knowledge to the point that conservation measures can be tangibly improved. The scope of such programmes will be developed in consultation with relevant parties to ensure the maximum benefit is delivered.

**Residual Impact**

Through the adoption of these mitigation measures the extent of habitat loss, risk of introduction of invasive species, and direct Project impacts on populations of Nikolski’s tortoise and marine species should be minimised. The development via a BAP of a mitigation strategy that will be designed to achieve net gains of those biodiversity values for which the critical habitat was designated is expected to address some of the key pressures on this species and increase awareness of the value of this species amongst the local population. As such the magnitude of the residual impact on the well-being of beneficiaries with mitigation is considered to be negligible and the overall significance of the impact is **Not Significant**.

**17.7.2.4 Residual Impacts: Construction and Pre-Commissioning**

The residual Project impacts during the Construction and Pre-Commissioning Phase are discussed in the above sections and a summary is presented in Table 17.15 below.

Chapter 17 Ecosystem Services

17.7.3 Assessment of Potential Impacts: Operational Phase

17.7.3.1 Introduction

In the following sections the key beneficiaries of each ecosystem service and the relevant Project impacts during the Operational Phase are discussed. For each of the ecosystem services the beneficiaries are grouped together and the Project impact is assessed in terms of the total impacts on that service across all of its beneficiaries. A detailed breakdown of the scoring assigned to each ecosystem service is provided in Appendix 17.4 Impact Assessment – Operational.

17.7.3.2 Assessment of Potential Impacts (pre-mitigation)

Crops

The impacts on beneficiaries of crop services in terms of vegetation clearance during construction, loss of land, and corresponding impacts on employment opportunities are discussed in Section 17.7.2.2. While these impacts are on-going and are likely to be felt during the Operational Phase (as crops are re-established) they are assessed as part of the Construction and Pre-Commissioning Phase as that is when the activities leading to the impacts are undertaken.

In terms of activities undertaken during the Operational Phase, there are none identified which could significantly impact provision or use of crops within the Affected Ecosystems or the well-being of beneficiaries of this service.

The Operational Phase is therefore likely to have a negligible impact magnitude and the impact significance is assessed as Not Significant. Crop production is therefore not considered to be a priority ecosystem service during the Operational Phase

Capture Fisheries

The specific Project activities during the Operational Phase that could impact upon capture fisheries include restriction of access to fishing grounds due to an exclusion zone, and noise disturbance from Pipeline operation (Appendix 14.1).

With regards to the exclusion zone, beyond approximately 600 m from the shoreline the Pipeline will lie unburied on the seabed creating a potential hazard for fishing vessels which could make contact with their gear. To ensure that the Pipeline and fishing vessels are not damaged during the Operational Phase (e.g. dragged anchors, fishing gear, etc.), exclusion zones will be put in place along the Pipeline route to restrict activities that may cause damage (such as bottom trawling).

While the final design of the exclusion zones will be agreed in consultation with the appropriate authorities, it is anticipated that they will extend to 0.5 km (0.27 NM) either side of the outermost pipelines from the microtunnel exit pit until the Russian / Turkish EEZ boundary. The full width of the exclusion zone would therefore be a corridor of up to approximately 1.5 km, allowing for the spread of the four pipes.
While there may be some inconvenience due to access restrictions, the loss of fishing ground will only affect bottom trawling which is limited in the area. Further, the area of the shelf suitable for bottom fishing within the exclusion zone represents an insignificant amount (2.4%) of the total shelf area shallower than 100 m.

With regards to noise disturbance, the presence of a pipeline on the seabed should neither pose a physical barrier to fish movement nor act as a deterrent noise source; particularly since the main migratory species are pelagic species which live in the waters well above the pipeline. Evidence from monitoring of the fisheries within the vicinity of the North Stream pipeline in the Baltic (which includes several species related to those in the Black Sea and the same species of sprat) shows no discernible impacts on fish catches.

As such, the likelihood of the fishing industry experiencing any reductions in catches during the operational phase is considered to be minimal and there are unlikely to be any distinguishable differences from normal annual fluctuations.

The impact magnitude is therefore considered negligible and the overall significance of the Operational Phase of the Project on capture fisheries is assessed as being Not Significant.

**Water (supply)**

Due to the use of tunnelling, operation of the Pipeline could lead to on-going obstruction of groundwater flows within the Local Area although the extent of such changes are likely to be minimal and are not expected to lead to a measurable change in the well-being of any beneficiaries. As such the impact magnitude is assessed as negligible and the overall impact is considered Not Significant.

**Hazard Regulation**

There are no identified activities during the Operational Phase that are likely to have a significant impact on provision of this service or the well-being of any beneficiaries. As described in Chapter 5 Project Description, regular monitoring and inspection of the Pipeline will be undertaken throughout the Operational Phase. This will enable any changes to the local environment, particularly those relating to seismic and geomorphological processes, to be identified and managed.

As such the impact magnitude is assessed as negligible and the overall impact significance is assessed to be Not Significant.

**Air Quality Regulation**

There are no identified activities during the Operational Phase that are likely to have a significant impact on provision of this service or the well-being of any beneficiaries. As such the impact magnitude is negligible and the overall impact significance is assessed to be Not Significant.
**Water Quality Regulation**

There are no identified activities during the Operational Phase that are likely to have a significant impact on provision of this service or the well-being of any beneficiaries. As such the impact magnitude is negligible and the overall impact is assessed to be **Not Significant**.

**Soil Quality Regulation**

There are no identified activities during the Operational Phase that are likely to have a significant impact on provision of this service or the well-being of any beneficiaries. As such the impact magnitude is negligible and the overall impact is assessed to be **Not Significant**.

**Tourism and Recreation Values**

There are no identified activities during the Operational Phase that are likely to have a significant impact on provision of this service or the well-being of any beneficiaries. As such the impact magnitude is negligible and the overall impact is assessed to be **Not Significant**.

**Cultural and Spiritual Values**

Operation of the Pipeline could lead to further disturbance of sites of cultural value, in particular the Varvarovka Armenian and Russian cemetery, as well as a change in the cultural and aesthetic value of the Local Area as an agricultural landscape due to noise and visual disturbance from the operation of the landfall facilities. Potential impacts on archaeological sites are discussed in **Chapter 16 Cultural Heritage**.

In terms of landscape changes, the use of microtunneling effectively minimises the potential impacts on the landscape and visual amenity due to Pipeline operation. There will be further visual impact due to the presence the proposed landfall section facilities include a metering facility, pipeline inspection gauge (PIG) traps and electrical and instrumentation installations. However, extensive woodland surrounding this area of the Project is effective at ‘absorbing’ development by screening much of the Project and the extent of any change is small relative to the total landscape (see **Chapter 13 Landscape and Visual**). Likewise, with regards to users of the cemetery, while there will be some visual impact it is unlikely to be of an extent which prohibits anyone from accessing the site or being able to derive spiritual value from the area due to the sensitive design of the microtunneling site access road.

As such, while there will be some visual change there are not expected to be any significant impacts on beneficiaries of cultural services and the impact magnitude is negligible. The overall impact significance is considered to be **Low**.

**Wild Species Diversity**

In the terrestrial Affected Ecosystems operational impacts resulting from the Project are limited given that all of the significant impacts on habitats as a result of habitat loss or fragmentation will have occurred at the Construction Phase. During the Commissioning and Operational Phase many of the mitigation measures for the impacts of construction (such as vegetation replanting) will occur. The overall impact of the Commissioning and Operational Phase will therefore be considerably lower than those during construction.
The overall impact on habitats during operation will be **Not Significant** due to the lack of any significant ground-works or other major works. The only activities that will be undertaken during this Project phase will be related to land remediation and maintenance of the RoW.

There is some potential for impacts on flora (including potentially red list species) as a result of maintenance to keep the RoW free of large trees and deep-rooted shrubs for the lifespan of the Project. However, considering that the worst case scenario of habitat and species loss for flora of conservation importance has been assessed for construction, the effect of operational activities is not likely to be significant.

There may be some disturbance to invertebrates, reptiles, birds, and mammals as a result of small-scale works, movement of vehicles and other machinery and vegetation clearance although there are unlikely to be any significant impacts on population viability or on the well-being of beneficiaries (see **Chapter 11 Terrestrial Ecology**).

The presence of the operational Pipeline within the marine environment is not expected to result in any significant impacts on benthic habitats, seabirds, marine mammals or fish. The movement of vessels (including noise) used for pipeline inspection and maintenance could periodically disturb some seabirds and marine mammals although the impacts on population viability and beneficiary well-being is unlikely to be significant (see **Chapter 12 Marine Ecology**).

Overall, the magnitude of impacts on beneficiary wellbeing are considered to be negligible and the impact **Not Significant**.

**17.7.3.3 Mitigation and Monitoring**

Based on the results of the impact assessment (see Appendix 17.4 for a detailed summary of the scoring assigned to each ecosystem service), there are no priority services likely to be significantly impacted during the Operational Phase of the Project and which will require further mitigation.

**17.7.3.4 Residual Impacts: Operational Phase**

Table 17.16 presents a summary of the residual effects of impacts on ecosystem services on their beneficiaries following mitigation.

17.7.4 Assessment of Potential Impacts: Decommissioning Phase

17.7.4.1 Introduction

Decommissioning of the South Stream Pipeline will be carried out according to prevailing international and national legislation and regulations and GIIP regarding environmental and other potential impacts. An assessment will be undertaken to confirm that the planned decommissioning activities are the most appropriate to the prevailing circumstances and future land use. The assessment of decommissioning impacts set out below is therefore provisional, based on current practices and technologies. It is not intended to be definitive, but may serve as a high level comparison between two alternative strategies:

- **Option 1** – In situ decommissioning which involves cleaning the Pipeline and filling it with seawater. The receptors that might be impacted are thus the same as those for the Operational Phase; and

- **Option 2** – Removal of the Pipeline which is essentially a similar operation to pipe-laying, but in reverse. The receptors and degree of impact will thus be similar to those identified for the Construction and Pre-Commissioning Phase.

17.7.4.2 Assessment of Potential Impacts (pre-mitigation)

Crops

Under Option 1 there are not likely to be any impacts on the provision or use of the crops service. As such the impact significance is **Not Significant**.

Under Option 2, the removal of the Pipeline will require clearance of an area of land similar to that required in the Construction and Pre-Commissioning Phase. This land may be used for productive agricultural uses depending on whether or not the area has been replanted following the vegetation clearance undertaken in the Construction and Pre-Commissioning Phase.

The receptor sensitivity in this Phase is likely to be high if the area of land currently fallow is planted at some point during the Operational Phase. Further, the projected changes in climate may make wine production more vulnerable to Project impacts and could increase the vulnerability of production if, for example, viticulture in the Local Area becomes increasingly challenging under a future climate thereby reducing the profitability of the enterprise.

Any loss of productive agricultural land would have an impact on the livelihoods of those employed on the land. Therefore, assuming that viticulture in the Local Area is still viable in 2065 and that at least the area currently in agricultural production is replanted following the Construction and Pre-Commissioning Phase, the Project could have an impact of **Moderate** significance.
Capture Fisheries

Under Option 1, there are not likely to be any significant impacts on fisheries productivity or on access to fishing grounds beyond the restrictions that exist during the Operational Phase. As such the significance of impacts is deemed **Not Significant**.

The removal of the Pipeline (Option 2) may result in disturbance from additional vessel movements and potentially the re-instatement of a wider exclusion zone around the vessels involved in decommissioning. This is unlikely to have a significant impact on fisheries productivity as the affected area is small relative to the total fishing area and fish are able to avoid the area of disturbance. As such, the significance of impacts is assessed as being **Not Significant**.

Water (supply)

Under Option 1 there are not likely to be any impacts on the provision or use of water (supply). As such the impact significance is **Not Significant**.

Under Option 2, the removal of the Pipeline could impact water supply for downstream users through the potential abstraction from aquifers for use in decommissioning activities leading to decreasing groundwater levels, and alterations to surface water flows during construction due to crossing of surface waters and alterations to vegetation cover.

Due to the on-going abstraction of water from groundwater aquifers throughout the Project’s life, groundwater levels are likely to be lower in 50 years’ time than at present. Further, factors such as the changing climate, projected decreases in water availability, potential population increases, new downstream water users, as well as growing demands for water in irrigated agriculture, could increase the sensitivity of water resources and their users to any changes in supply.

As such, the receptor sensitivity for this service is likely to be higher in this Phase than in the Construction and Pre-Commissioning Phase. However, the Project is unlikely to significantly alter water flows or the ability of any beneficiaries to access water. As such, the impact on well-being is likely to be negligible and the impact significance is assessed as **Low** significance.

Hazard Regulation

Under Option 1 there are not likely to be any impacts on the provision or use of hazard regulation services. As such the impact significance is **Not Significant**.

Under Option 2, the removal of the Pipeline could impact hazard regulation through site clearance and earthworks, particularly where these result in loss of vegetation; preparation of foundations which may induce tremors that trigger mass movement of soils; impacts on the structural composition of Phaeozem soils which play an important role in water storage and flow regulation; and any dredging activities which could impact upon coastal processes and the effects of sea surges.

Climate change projections are likely to increase the frequency of hazards in the region although it is not possible to accurately predict changes in the Local Area at this stage. Any
growth in populations in the Local Area could increase the amount of people vulnerable to hazards.

While the likelihood of any impact on beneficiaries well-being is likely to be low the receptor sensitivity is likely to be higher due to the impacts of climate change and, as such, the impact significance is assessed as **Moderate** significance.

**Air Quality Regulation**

Under Option 1 there are not likely to be any impacts on the provision or use of air quality regulation services. As such the impact significance is **Not Significant**.

Under Option 2, vegetation clearance and emissions during decommissioning activities could reduce the ability of the Affected Ecosystems to regulate air quality. However, as in the Construction and Pre-Commissioning Phase, due to the limited extent of emissions and vegetation loss relative to the surrounding ecosystem cover the impact on air quality and the well-being of beneficiaries of this service is not likely to be significant.

Warming of the climate could reduce the uptake of pollutants by vegetation in the Local Area and further development which requires vegetation clearance could reduce the extent of natural habitat which can play this role. As such the ecosystem receptors are likely to be higher sensitivity to any Project impacts.

While the receptor sensitivity is likely to be higher, the likelihood of any impact on beneficiaries well-being is likely to be negligible. As such, the impact significance is assessed as **Not Significant**.

**Water Quality Regulation**

Under Option 1 there are not likely to be any impacts on the provision or use of water quality regulation services. As such the impact significance is **Not Significant**.

Under Option 2, the Project could lead to higher pollution levels in surface and ground waters due to decommissioning activities and removal of vegetation; accidental leaks and spills; impacts on mussels and other marine organisms capable of biofiltration if present in 50 years’ time; and seabed disturbance and release of sediments into the marine water column as a result of dredging and pipeline removal.

Assuming that the regulatory frameworks for improving water quality in the Local Area are implemented successfully, inputs of pollution into the marine and freshwater ecosystems should be lower by 2065. As such, receptor sensitivity would be lower and the impact significance is assessed as **Low** significance.

**Soil Quality Regulation**

Under Option 1 there are not likely to be any impacts on the provision or use of soil quality regulation services. As such the impact significance is **Not Significant**.

Under Option 2, the Project could reduce the ability of ecosystems to regulate soil quality through an increase in concentration of contaminants through leaks, spills, and emissions;
increased susceptibility of soil to erosion through clearance of vegetation and excavation works; loss of nutrients and soil carbon due to soil excavation and removal of vegetation which contributes to soil composition; degradation of soil, physical damage, and compaction through stockpiling of soils during decommissioning; and displacement of soils through effects on the river channel.

While pressures on soil resources and the ability of ecosystems to regulate soil quality may increase over the life of the Project due to increased levels of development in the Local Area, vegetation clearance, growing air borne emissions, and greater pollutant from surface runoff, there is unlikely to be a significant change in the sensitivity of the receptors or the potential Project impacts. As such, the impact significance is assessed as **Moderate** significance.

**Tourism and Recreation Values**

Under Option 1 there are not likely to be any impacts on the provision or use of tourism and recreation services. As such the impact significance is **Not Significant**.

Under Option 2, the Project could reduce the ability of ecosystems to provide opportunities for tourism and recreation primarily through visual disturbance to beach users and visitors to nearby resort complexes. The receptor sensitivity and impact magnitude are likely to be similar to the Construction and Pre-Commissioning Phase and, as such, the impact significance is assessed as **Moderate** significance.

**Cultural and Spiritual Values**

Under Option 1 there are not likely to be any impacts on the provision or use of cultural and spiritual services. As such the impact significance is **Low** significance.

Under Option 2, the Project could damage the aesthetics and agricultural nature of the landscape as well as causing damage to sites of cultural importance and their environmental setting. The receptor sensitivity and impact magnitude are likely to be similar to the Construction and Pre-Commissioning Phase and, as such, the impact significance is assessed as **Moderate** significance.

**Wild Species Diversity**

Under Option 1 there are not likely to be any impacts on wild species diversity. As such the impact is assessed as being **Not Significant**.

Under Option 2, the Project could impact on wild species diversity through habitat loss, disturbance during decommissioning activities, pollution incidents, and introduction of invasive species. The receptor sensitivity and impact magnitude are likely to be similar to the Construction and Pre-Commissioning Phase and, as such, the impact significance is assessed as **High** significance.

**17.7.4.3 Mitigation and Monitoring**

Based on the results of the impact assessment there are no priority services identified for Option 1 and six priority ecosystem services identified for Option 2:
- Crops;
- Hazard regulation;
- Soil quality regulation;
- Tourism and recreation values;
- Cultural and spiritual values; and
- Wild species diversity.

Due to the similar nature of the impacts the mitigation requirements for the second options of the Decommissioning Phase are likely to mirror those required for the Construction and Pre-Commissioning Phase. As such, the mitigation requirements will be similar to those set out in Section 17.7.2.3, although a full EIA will need to be undertaken prior to decommissioning to ensure that the impact assessment and mitigation recommendations are still appropriate.

Hazard regulation is the only service which was not identified as a priority service in the Construction and Pre-Commissioning Phase. The increase in significance is due to the likely increase in hazard risk due to climate change within the Local Area. While the nature of such risks are difficult to predict at present, there could be increases in surface water flooding, coastal erosion, coastal flooding, and mudflows (as a result of more intense rainfall patterns).

In order to mitigate impacts on this service during the Decommissioning Phase, a detailed, quantitative study of hazard risk in the Local Area should be undertaken prior to decommissioning and used to inform appropriate mitigation measures.

### 17.7.4.4 Residual Impacts: Decommissioning Phase

Table 17.17 presents a summary of the residual effects of impacts on ecosystem services on their beneficiaries following mitigation.

17.8 Unplanned Events

Unplanned events are considered separately from planned activities as they only arise as a result of a technical failure, human error, or as a result of natural phenomena such as a seismic event. As such, unplanned events are assessed and relevant mitigation measures are presented in Chapter 19 Unplanned Events. Those relevant to the provision or use of ecosystem services include fuel and oil spillages; fire risk; introduction of invasive non-native species into the marine environment; and large scale release of natural gas.

Spillages of fuel and oil during construction activities could potentially have widespread impacts on a range of services provided by both terrestrial and marine ecosystems including crops, fisheries, and tourism and recreation. However, through adherence with the Spill Prevention and Response Plan, it is concluded that the actions taken will prevent any long term significant adverse impacts on the environment as a result of such events.

Fire risks during construction will be minimised through the definition and enforcement of strict control measures, which will include the adoption of a "permit to work" system for hot works and a smoking ban for all construction personnel whilst undertaking construction activities. Additional measures will include the development of an Emergency Response Plan, inclusive of fire prevention and suppression measures which will be developed and maintained by each construction contractor. The Emergency Response Plan will include specific measures to prevent the spread of any fires to the natural habitats within the Project Area.

Vessel operations during construction also have the potential to inadvertently introduce invasive alien species, either in ballast water, on the biofilm inside ballast tanks, or carried as fouling organisms on the hull. Despite its low probability of occurrence, the possibility of population or community-wide effects on the entire ecology of the sea makes this a potentially highly significant impact with potential impacts on a range of services including fisheries, water quality, and wild species diversity. In order minimise the risk of accidental introductions, appropriate mitigation measures will be implemented as set out in Chapter 19 Unplanned Events.

During the Operational Phase, unplanned events are similar to those listed above for the Construction and Pre-Commissioning Phase however there is also a risk of large scale releases of un-ignited natural gas from the pipelines. The majority of failures would be small, e.g. pin-hole releases from valve stems and flanges, and the frequency of catastrophic events that may cause a long-term shutdown is extremely low. Further detail is contained in Chapter 19 Unplanned Events.

17.9 Cumulative Impacts Assessment

Cumulative impacts associated with the Project are assessed in Chapter 20 Cumulative Impact Assessment.
17.10 Conclusions

A total of ten ecosystem services were scoped into the assessment in this chapter. For these ten services, the significance of the Project’s impacts during the Construction and Pre-Commissioning Phase before mitigation was assessed as follows:

- **Not Significant**: Capture fisheries, water supply, and air quality regulation;
- **Low**: Hazard regulation and water quality regulation;
- **Moderate**: Crops, soil quality regulation, tourism and recreation values, and cultural and spiritual values; and
- **High**: Wild species diversity.

During the Operational Phase, the impacts on cultural and spiritual values were found to be of **Low** significance and impacts on all other services were found to be **Not Significant**.

The assessment therefore identifies five priority services on which the Project would likely have a significant impact (pre-mitigation) during the Construction and Pre-Commissioning Phase. No priority services are expected to be impacted during the Operational Phase. A summary of the priority services, the likely impacts, the proposed mitigation measures, and residual impacts is provided in Table 17.18.

BAP with ecosystem service considerations where possible | Not significant |

The mitigation measures identified are intended to anticipate and avoid, or where avoidance is not possible, minimize, and, where significant residual impacts remain, compensate / offset impacts on receptors. Assuming that the mitigation measures suggested in this assessment are successfully implemented, it will be possible for the Project to mitigate all adverse effects associated with the Project to the degree that most impacts after mitigation would be low or not significant.

Hazard regulation was identified as an additional priority service during the Decommissioning Phase if the option to remove the Pipeline is selected. However, as the approach has not yet been decided and due to the large degree of uncertainty of assessing impacts over this timeframe, appropriate mitigation should be determined based on a survey of the risks nearer the time of decommissioning.

The combined effects of the Project and other developments are not expected to result in any significant cumulative impacts on ecosystem service beneficiaries.

18 Waste Management

18.1 Introduction

This chapter presents an assessment of the potential waste arising from the Project. It relates to solid waste, non-aqueous liquid waste, and wastewater generated from treatment of sewage.

The methodology used to assess potential waste impacts differs slightly from that detailed in Chapter 3 Impact Assessment Methodology due to the unique nature of waste when considered as a Project impact. Unlike many other impact categories, waste is a product of the Project and impacts from waste will depend on the ability of facilities and management systems to store, transport, treat and dispose of waste in a safe and environmentally sound manner. There are a number of applicable legislative requirements and standards that exist which must be adhered to, as well as a range of potential waste management mitigations and practices that can be applied.

This chapter describes the legal and regulatory framework applicable to the Project based on wastes anticipated to be generated by Project activities (see Chapter 5 Project Description). In light of this, available waste facilities capable of receiving anticipated Project wastes are identified (Section 18.2).

The waste impact assessment section (Section 18.4) identifies the type and volume of wastes anticipated and describes the potential impacts arising from the management of wastes (e.g. impacts on human health and the environment from releases of waste to air, water or land; potential nuisance to humans and fauna). It is recognised that impacts can arise throughout the waste management process and therefore the generation, storage, collection and transport, reuse, recycling, recovery, treatment and disposal of waste are considered. In contrast to other chapters, pre-mitigation significance of impacts is not assessed in this chapter because it is not realistic to consider any situation in which management or mitigation would not be carried out; legislation dictates requirements for waste storage, management and disposal, and these are therefore considered part of the Project design.

The legal requirements for waste management and mitigation measures for the Project (e.g. waste minimisation) are described and the residual impacts are then assessed (Section 18.5). Mitigation measures that will be adopted to manage anticipated wastes so as to minimise their environmental impact and ensure compliance with relevant local, national and international regulations are provided. These approaches represent standard Good International Industry Practice (GIIP) for the various waste streams under consideration and make use of existing local facilities as far as practicable. The assessed significance of the residual impacts for each waste stream takes into account the identified mitigation measures.

The Project Environmental and Social Management Plan (ESMP) (described in Chapter 22 Environmental and Social Management) describes how the mitigation measures detailed within this chapter shall be practically applied to the construction and operation of the Project.
18.1.1 Applicable Legislation, Standards, and Guidelines

Chapter 2 Policy, Regulatory and Administrative Framework describes the framework of legislation, standards and guidelines relevant to the ESIA; those of particular relevance to waste management are summarised below.

18.1.1.1 International Legislation

There are four international conventions associated with waste management that are relevant in the context of this ESIA Report. Table 18.1 highlights the most relevant parts of these conventions in relation to waste management aspects of the Project.

Table 18.1 Summary of International Waste Management Requirements

<table>

<tr>
<td>Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter (London Convention), 1972</td>
<td>The objective of the London Convention is to control pollution of the sea caused by dumping activities and to encourage supplementary regional agreements. As such, it covers the deliberate disposal at sea of wastes or other matter from vessels, aircraft and platforms. Under these requirements, Parties are to establish authorities responsible for issuing permits, keeping records and monitoring the condition of the seas. Furthermore, Parties are to promote measures which prevent pollution from hydrocarbons, additional matter transported other than for dumping, wastes generated during operation of ships, etc. and matter originating from exploration of the sea bed. Annexes I and II of the London Convention list matter which is defined as prohibited or restricted with regards to dumping.</td>
</tr>
<tr>
<td>(Russia is a Party to the London Convention)</td>
<td></td>
</tr>
</tbody>
</table>
| Convention on the Control of Transboundary Movements of Hazardous Wastes and Their Disposal (Basel Convention), 1992 | The Basel Convention regulates transboundary movements of hazardous wastes and provides obligations upon its Parties to ensure that such wastes are managed and disposed of in an environmentally sound manner. The main principles of the Convention are as follows:  
  - Transboundary movements of hazardous wastes should be reduced to a minimum, which is consistent with their environmentally sound management;  
  - Hazardous wastes should be treated and disposed of as close as possible to their source of origin; and  
  - Hazardous waste generation should be reduced and minimised at source.  
  Annexes I–VIII of the Basel Convention provide lists of waste categories requiring special consideration or controls, including disposal operations.  
  Annex I outlines a list of waste categories to be controlled, Annex II details waste categories requiring special consideration and Annex III provides a list of important hazardous characteristics. |
<p>| (Russia is a Party to the Basel Convention)                          |                                                                                                                                                                                                          |</p>

</tr>
</thead>
<tbody>
<tr>
<td>Convention on Persistent Organic Pollutants (Stockholm Convention)</td>
<td>The Convention seeks to ensure the limitation of pollution by persistent organic pollutants (POPs). It defines the substances in question, whilst leaving open the possibility of adding new ones, and also defines the rules governing the production, importing and exporting of those substances.</td>
</tr>
<tr>
<td>(Russia has signed and ratified the Stockholm Convention)</td>
<td></td>
</tr>
<tr>
<td>International Convention for the Prevention of Pollution from Ships,</td>
<td>The Convention covers the prevention of pollution of the marine environment by ships from operational or accidental causes. With regards to waste management, the Convention defines conditions for waste disposal in the marine environment by ship, particularly in determined “special areas” such as the Black Sea. Annex I includes regulations for the Prevention of Pollution by Oil and is mandatory. Annex II includes regulations for the Control of Pollution by Noxious Liquid Substances in Bulk. Annex III includes regulations for the Prevention of Pollution by Harmful Substances Carried by Sea in Packed Form. Of particular relevance to waste management aspects of the Project are Annex IV and Annex V. Annex IV includes regulations for the Prevention of Pollution by Sewage from Ships. Annex V includes regulations for the Prevention of Pollution by Garbage from Ships. Annex VI includes regulations for the Prevention of Air Pollution from Ships.</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>Annex I – VI (Ref. 18.4).</td>
<td></td>
</tr>
<tr>
<td>(Russia has acceded to Annexes I to VI of the MARPOL Convention)</td>
<td></td>
</tr>
<tr>
<td>Convention on the Protection of the Black Sea Against Pollution</td>
<td>The Convention provides a basic framework of agreement and three specific Protocols, which are: (1) the control of land-based sources of pollution; (2) control of dumping of waste; and (3) joint action in the case of accidents (such as oil spills). Discharges from ships are managed accordance with MARPOL and are as such compliant with the Bucharest Convention. The &quot;Protocol on the Protection of the Black Sea Marine Environment Against Pollution by Dumping” does not apply to any of the wastes generated by the project in the Russian EEZ since the project activities in these waters do not comprise dumping as defined in the Convention.</td>
</tr>
<tr>
<td>(Bucharest Convention), 1992</td>
<td></td>
</tr>
<tr>
<td>(Russia has signed and ratified the Bucharest Convention)</td>
<td></td>
</tr>
</tbody>
</table>

Of these international conventions, the most relevant to the Project is MARPOL 73/78 Convention, which governs management of waste on board vessels. The Black Sea is a Special Area under MARPOL Annexes I and V. Amendments to Annex V entered into force on 1 January 2013, and the revised Annex V prohibits the discharge of all garbage into the sea, except as provided otherwise. An overview of the revised MARPOL Annex V discharge provisions (as relevant to the Project) is presented in Table 18.2 below.

Under MARPOL Annex I, any discharge of oil from a ship exceeding 400 gross registered tonnage (GRT) is prohibited within any Special Area, as defined by the Annex, except when:

- The ship is proceeding en route;
- The oily mixture is processed through an oil filtering equipment meeting the relevant MARPOL requirements;
• The oil content of the effluent without dilution does not exceed 15 parts per million;
• The oily mixture does not originate from cargo pump room bilges on oil tankers; and
• The oily mixture, in case of oil tankers, is not mixed with oil cargo residue.

The Black Sea is a Special Area under MARPOL Annex I. This effectively prohibits the discharge of oily sludge and slops, and requires oily bilge water to be treated through an oily water separator (OWS) prior to discharge.

Annex IV of the MARPOL 73/78 Convention provides regulations for the prevention of pollution by sewage from ships. MARPOL Annex IV defines "sewage" as:
• Drainage and other wastes from any form of toilets and urinals;
• Drainage from medical premises (dispensary, sick bay, etc.) via wash basins, wash tubs and scuppers located in such premises;
• Drainage from spaces containing living animals; or
• Other waste waters when mixed with the drainages defined above.

The discharge of sewage into the sea is prohibited, except when:
• The ship is discharging comminuted and disinfected sewage at a distance of more than 3 nautical miles from the nearest land, or sewage which is not comminuted or disinfected at a distance of more than 12 nautical miles from the nearest land, provided that in any case, the sewage that has been stored in holding tanks shall not be discharged instantaneously but at a moderate rate when the ship is en route and proceeding at not less than 4 knots; or
• The ship has in operation an approved sewage treatment and (additionally) the effluent shall not produce visible floating solids nor cause discoloration of the surrounding water.

Annex V of the MARPOL 73/78 Convention provides regulations for the prevention of pollution by garbage from ships and limits the disposal, be it continuous or periodic, of food, domestic and operational waste into the sea. Annex V completely prohibits the disposal of plastics anywhere into the sea and places strict restrictions upon discharges into designated Special Areas. The Black Sea is a Special Area under Annex V.

</tbody>
</table>

<sup>a</sup> These substances must not be harmful to the marine environment.

<sup>b</sup> According to regulation 6.1.2 of MARPOL Convention Annex V, the discharge shall only be allowed if: (a) both the port of departure and the next port of destination are within the special area and the ship will not transit outside the special area between these ports (regulation 6.1.2.2); and (b) if no adequate reception facilities are available at those ports (regulation 6.1.2.3).

### 18.1.1.2 International Standards and Guidelines

In addition to the international legislation outlined above, the Project is aligned with the IFC EHS Guidelines and Performance Standards (PS). Table 18.3 summarises the IFC EHS Guidelines and PS that require consideration in relation to waste management aspects of the Project.
Table 18.3 IFC Guidelines and Performance Standards Relevant to Waste Management

<table>
<thead>
<tr>

</tr>
</thead>
</table>
| IFC (2007) General EHS Guidelines: Environmental (Ref. 18.5). | The IFC EHS Guidelines are technical reference documents that provide general and industry-specific examples of Good International Industry Practice (GIIP). The Guidelines cover a wide range of technical subjects, including hazardous and non-hazardous waste management. Section 1.5 Hazardous Waste Management states that:

"Projects which manufacture, handle, use, or store hazardous materials should establish management programs that are commensurate with the potential risks present. The main objectives of projects involving hazardous materials should be the protection of the workforce and the prevention and control of releases and accidents. These objectives should be addressed by integrating prevention and control measures, management actions, and procedures into day-to-day business activities."

Section 1.6 Waste Management states that:

"Facilities that generate and store wastes should practice the following:

establishing waste management priorities at the outset of activities based on an understanding of potential Environmental, Health, and Safety (EHS) risks and impacts and considering waste generation and its consequences;

establishing a waste management hierarchy that considers prevention, reduction, reuse, recovery, recycling, removal and finally disposal of wastes;

avoiding or minimizing the generation waste materials, as far as practicable;

where waste generation cannot be avoided but has been minimized, recovering and reusing waste;

where waste cannot be recovered or reused, treating, destroying, and disposing of it in an environmentally sound manner."

**Name** | **Relevance**
--- | ---
IFC PS3: Resource Efficiency and Pollution Prevention (1 Jan 12) (Ref. 18.6). | The IFC provides eight Performance Standards that offer guidance regarding the identification of risks and impacts associated with projects, and which aim to reduce, avoid or mitigate these risks and impacts. Of relevance to waste management is Performance Standard 3: Resource Efficiency and Pollution Prevention. The aim of this standard is to minimise or avoid adverse impacts on human health and the environment, promote sustainable use of resources and reduce greenhouse gas emissions. Performance Standard 3 states that the client will avoid generation of hazardous and non-hazardous materials, but where waste cannot be avoided, waste arisings will be reduced, recovered or reused before subjecting the materials to treatment and disposal in an environmental sound manner. Waste disposal should be at sites operating to acceptable standards and, where this is not the case, consideration should be given to alternative disposal options, including the development of facilities on site. The use and production of hazardous waste should be avoided as far as is possible and, where this is not practicable, material will be controlled and minimised.

IFC PS3 Guidance Note: Resource Efficiency and Pollution Prevention (01 Jan 2012) (Ref. 18.7). | To aid in the interpretation of IFC Performance Standards, Guidance Notes relevant to each standard are also provided. Guidance Note 3 corresponds to Performance Standard 3 and outlines further details regarding the management of hazardous and non-hazardous wastes. With regard to hazardous waste, Guidance Note 3 lists International Conventions the client should refer to when reviewing components of materials and hazardous waste; these conventions are listed in the Bibliography of Guidance Note 3.

**18.1.1.3 National Waste Management Legislation**

In addition to international legislation and standards, the Project will also be undertaken in accordance with relevant national waste management legislation and requirements. A list of national legislation relevant to waste management aspects of the Project is provided in Table 18.4.

As part of the Russian regulatory approvals process, the Project proponent is required to estimate the types and quantities of waste to be produced by the Project. Following initial approvals, it is necessary to prepare a list of waste types and limits which is submitted to the regulatory authorities, and following their approval a certificate will then be issued which specifies the Waste Generation Standards and Waste Disposal Limits for the Project.

Waste producers are obligated to keep proper records of the wastes generated, treated, and handed over to other parties, fill out government statistical reports, and pay an Adverse Environmental Impact Fee based on the approved waste types and quantities. Penalty fees are payable in the event that waste quantities exceed those approved prior to project commencement.

</thead>
<tbody>
<tr>
<td>Federal Law ‘On Production and Domestic Wastes’ (Ref. 18.8).</td>
<td>24 Mar 1998, No. 89-FZ</td>
<td>Federal Law No. 89-FZ outlines the legal basis for the management of production and consumption wastes for the purpose of preventing negative impacts upon human health and the environment. The law establishes environmental requirements and monitoring of waste management activities, economic regulations related to waste and discusses issues regarding waste ownership (i.e. the proprietor of waste). In addition, the law is supported by various secondary laws regarding the implementation of waste management requirements. The main principles of Federal Law No. 89-FZ include the following: Specifically designated federal executive authorities for waste management; Identification of the proprietor of waste; Licensing of hazardous waste management activities; Determining categories of hazardous waste; Certification procedures for hazardous waste; and Determining the basis for state inventory of hazardous waste. The law also discusses the distribution of waste management roles between federal executive bodies and corresponding bodies at the regional and municipal level.</td>
</tr>
<tr>
<td>Federal Law ‘On Licensing Activities’ (Ref. 18.9).</td>
<td>8 Aug 2001, No. 128-FZ</td>
<td>Federal Law No. 128-FZ determines the types of waste activities that are subject to licensing. It includes general provisions concerning issue of licenses, validity of licenses, etc.</td>

<td>Federal Law 'On the Protection of the Environment' (Ref. 18.10).</td>
<td>30 Dec 2008, No. 309-FZ</td>
<td>Federal Law No. 309-FZ includes a list of features used to categorise industrial facilities as hazardous industrial facilities. This list outlines properties of hazardous substances that may be received, used, processed, produced, stored, transported or destroyed by a hazardous industrial facility, as well as toxic substances and environmentally hazardous substances. Operational conditions of equipment employed at hazardous industrial facilities in relation to pressure and water-heating temperatures are also discussed. The list further summarises transport mechanisms (i.e. stationary lifting mechanisms, escalators, cableways or funicular railways), production of molten ferrous and non-ferrous metals and alloys and conduction of mining, mineral-enrichment and underground operations used by hazardous industrial facilities.</td>
</tr>
<tr>
<td>Government Enactment 'On the adoption of procedure for development and adoption of environmental standards for emission and discharge of polluting substances into the environment, limits for natural resources' use and waste disposal' (Ref. 18.11).</td>
<td>3 Aug 1992, No. 545</td>
<td>Environmental standards for emission and discharge of polluting substances into the natural environment, the maximum use of natural resources and waste disposal limits are set for specific enterprises, institutions, organisations and the Ministry of Natural Resources and Environment of the Russian Federation by the Health and Welfare supervisory authorities, in accordance with their competence. Documents specifying the normative values are developed by specific enterprises, institutions and organisations. The adopted procedure therein lost force to the extent it is applicable to development and adoption of limits for waste disposal.</td>

<td>Guidelines and procedures for charging environmental pollution payment (Ref. 18.25)</td>
<td>26 Jan 1993</td>
<td>The Guidelines and procedures specify application of the basic norms of payment for emissions, discharges of polluting substances into the natural environment, waste disposal, coefficients with regard to environmental factors and payment indexation rates in connection with price level changes and setting the maximum size of payment for environmental pollution, waste disposal and other adverse impacts. Adopted as per Resolution by the Government of the Russian Federation of August 28, 1992 No. 632 and put into effect since January 1, 1993. Payment for pollution of the natural environment is charged from users (production facilities, institutions, organisations and other legal entities regardless of their business legal structures and forms of incorporation), which exercise the right to perform production-commercial activities in the territory of the Russian Federation.</td>
</tr>
</tbody>
</table>
18.1.1.4   Russian Federal Waste Classification Catalogue

In accordance with Federal Law, Russia classifies waste based on its origin, physical state, hazardous properties and class of environmental hazard, in accordance with criteria established by the Federal Executive Authority responsible for regulating environmental protection.

In Russia, the Ministry of Natural Resources and Environment (MNRE) is responsible for monitoring and enforcing waste classification, as well as managing waste management activities including data collection and reporting. The MNRE has developed and approved criteria for classifying waste according to the Federal Waste Classification Catalogue (FWCC), approved by Decree Order No. 786 and No.663 (see Table 18.4).

The FWCC provides each class of waste with a thirteen digit code. The thirteenth digit in the code indicates the class of hazard to the environment. There are five hazard classes, whereby Hazard Class I wastes are deemed the most hazardous and Hazard Class V wastes are considered to be practically non-hazardous. Hazard Class 0 relates to wastes for which the class of hazard has not been established.

Wastes categorised as Hazard Classes I to IV require a license to be granted by the MNRE for the proposed waste management activity. Table 18.5 provides example waste streams for each of the five Hazard Classes, in accordance with the FWCC.

<td>Hazardous or Non-hazardous (depending on composition)</td>
</tr>
</tbody>
</table>

If wastes are generated that are classed according to the FWCC as Hazard Class “0” (i.e. Hazard Class not identified) then identification of the Hazard Class is based on the document ‘Criteria for Classifying Hazardous Waste as Hazardous to the Environment’, approved by Order of the MNRE of Russia No.11. The Hazard Classes for such wastes are determined by the ‘Calculation of the Class of Hazard 2.1’ (c) INTEGRAL 2001-2003 software.

### 18.1.1.5 Regional and Local Waste Management Legislation

There are no regional or local waste management regulations which are relevant to this assessment.

### 18.2 Baseline Conditions

The Strategic Action Plan (SAP) for the Environmental Protection and Rehabilitation of the Black Sea (adopted in Sofia, Bulgaria, 17 April 2009) (Ref. 18.26) includes a number of provisions related to waste management.

Waste management itself is not one of the priority transboundary problems identified in the SAP, although oil pollution is recognised as an aspect of chemical pollution, which is one of the four priority problems.

The SAP presents Ecosystem Quality Objectives (EcoQOs), which are statements that reflect how stakeholders would like the state of the Black Sea to be over the long term, based on a resolution of priority problems identified in the Transboundary Diagnostic Analysis. Each EcoQO is assigned a number of management targets that address the immediate, underlying and root causes of the concern areas. For regional level interventions, the Black Sea coastal states and
the international partners shall work collectively to take the required steps to fulfil those interventions. National level supporting interventions will be the responsibility of individual states.

Several of these management targets relates to waste management:

- **Target (18):** Amend national waste strategies and/or national coastal zone management plans with the aim of coastal and marine litter minimisation;
- **Target (19):** Develop regional and national marine litter monitoring and assessment methodologies on the basis of common research approaches, evaluation criteria and reporting requirements;
- **Target 20:** Promote / develop investment projects within national strategies / local plans to engineer, construct and install new solid waste recycling facilities, landfill sites and incineration plants, complying with BAT regulations;
- **Target (60):** Provide adequate port reception facilities for ship-generated wastes according to MARPOL 73/78, Annex I, IV, V;
- **Target (61):** Establish a harmonised fee / cost recovery system on ship-generated waste;
- **Target (62):** Develop systems for the identification of illegal pollution sources from vessels and off-shore installations; and
- **Target (63):** Develop / establish a harmonised enforcement system in cases of illegal discharges from vessels and off-shore installations, including technical means and fines.

The SAP presents indicators for each target, although a status update has not been published by the Black Sea Commission.

### 18.2.1.1 Existing Waste Management Arrangements

Table 18.6 outlines some of the existing waste management facilities in the vicinity of the Project (including waste types and capacity). The EPC contractor carrying out the works for the Project will be likely to use one or more of these facilities.

Site visits to two key waste facilities were undertaken in 2013 by South Stream Transport. Representatives visited the ECObio Waste Treatment Facility, near Krymsk, and the Alfa Landfill Facility, near Anapa, on the 18 April 2013, to evaluate these facilities for their suitability to manage Project wastes. South Stream Transport’s observations are summarised in Table 18.6 below and have been used as part of the assessment in Section 18.4.
<table>
<thead>
<tr>
<th>Name</th>
<th>Location</th>
<th>Types of Waste which the Facility is Licensed to Accept</th>
<th>Licensed capacity</th>
<th>Site Observations</th>
</tr>
</thead>
</table>
| Alfa Landfill Facility      | Anapa, Krasnodar      | Class IV and V: Non-hazardous soils, welding electrodes, crushed stone, used sands, plastic containers, cardboard, tree stumps | 140,000 tonnes per year | The landfill does not appear to be an engineered landfill and has no obvious means of leachate or gas management, or any effective lining or capping systems.  
The landfill is planned to close in 2016 (a closure plan is reported to be in place) by which time a new engineered landfill is planned to be in operation: the location for this new landfill has yet to be confirmed. |
| Research & Production       | Nizhnebakansky,       | Class III: Oily sludges, used oils, oily rags, sand contaminated with oils, oily residues from separators                  | Facility has confirmed capacity to accept up to 100,000 tonnes of waste drilling sludge as well as smaller quantities of other oil-contaminated wastes. | The site is located in a former quarry and is licenced to backfill the quarry with bioremediated class III waste – drilling cuttings or polluted soil. The site has 3 main treatment cells, and a number of disposal areas. The treatment cells are concrete lined, and are sequentially filled with contaminated material which undergoes bioremediation prior to final disposal.  
The site is securely fenced, internal access roads are in good condition, and an environmental monitoring regime is in place. Site observations indicate that the facility is likely to be operating in accordance with good international industry practice. |
<p>| Enterprise EcoBio LLC       | Krasnodar             | Class IV: Waste drilling sludge, waste drilling fluid, slurry from treatment plants, oily spent carbon filters              |                         |                                                                                                                                                   |</p>

</tbody>
</table>
Existing Port Waste Management Facilities

Existing waste management facilities at Temryuk and Novorossiysk Ports will be used for the management of wastes generated by the Project’s offshore activities.

The Ports of Temryuk and Novorossiysk have arrangements in place with port waste management companies to provide waste reception facilities for vessels using the port, and these contractors include:

- Marine Consulting LLC;
- Mortrans-Service NHB LLC;
- SPC Crocus LLC; and
- Krymskvtorsyryo LLC.

The contractor managing the vessels used for the Project will arrange with one or more of these port waste management companies to receive vessel waste, depending on which port is used, and the port waste management company will be responsible for the onward transportation and management of the vessel waste, using the existing regional disposal and treatment facilities as described in Table 18.3. Further inspection of the waste management facilities will be undertaken prior to completion of waste management contracts, i.e. to confirm that sufficient capacities are available to manage Project wastes legally and safely, in accordance with the requirements set out in Section 18.5 and the suite of Construction and Operational Phase Management Plans (refer to Chapter 22 Environmental and Social Management).

18.3 Methodology and Assessment Criteria

In contrast to other environmental and social technical disciplines in this ESIA Report, this chapter describes the estimated waste arisings, but does not assess the significance of these impacts in the absence of mitigation, since waste storage, management and disposal is considered part of the Project design, and as such it is not realistic to consider any situation in which no mitigation would be carried out. The mitigation section therefore describes the measures that will be adopted to manage the wastes generated by the project (including identifying potentially suitable facilities), and the significance of residual impacts following mitigation is then assessed.

Impact magnitudes for the residual impacts following mitigation are assessed based on:

- The hazardous properties (physical, chemical and biological) of the relevant waste stream; and
- The availability of suitable waste management facilities, taking into consideration: (a) the volume of waste produced, (b) the capacity of the identified waste management facilities for managing the waste in compliance with relevant guidelines, and (c) the degree of certainty in the availability of these facilities.

Table 18.7 presents a matrix that compares waste type and the availability of suitable waste management facilities, to determine impact magnitude (negligible, low, moderate, and high).
Table 18.7 Magnitude of Waste Impacts

<table>
<thead>
<tr>
<th>Waste Management Option</th>
<th>Type of Waste</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Inert</td>
</tr>
<tr>
<td>Suitable facilities or outlets available with sufficient capacity to manage the quantities of wastes generated</td>
<td>Negligible</td>
</tr>
<tr>
<td>Suitable facilities or outlets available but capacity to accept waste from project may be constrained due to size of facility or distance from site</td>
<td>Low</td>
</tr>
<tr>
<td>Facilities are unavailable or unsuitable; or means of management is uncertain.</td>
<td>Moderate</td>
</tr>
</tbody>
</table>

Since receptor sensitivity was assumed to be constant, the rankings (negligible, low, moderate, and high) delivered by the impact magnitude matrix in Table 18.7 also reflect “impact significance”; the definitions of significance detailed in Chapter 3 Impact Assessment Methodology are therefore applicable.

The definition of hazardous waste includes any wastes specifically designated as hazardous within applicable legislative requirements (e.g. hazardous wastes listed under the Russian Federal Waste Classification Catalogue (FWCC)). For the purposes of this ESIA Report, hazardous wastes are also defined in terms of the International Finance Corporation (IFC) General Environmental, Health and Safety (EHS) Guidelines for Waste Management (Ref. 18.7), i.e. wastes that share the properties of a hazardous material (e.g. ignitability, corrosivity, reactivity, or toxicity), or other physical, chemical, or biological characteristics that may pose a potential risk to human health or the environment if improperly managed. Inert waste is not defined in the FWCC but is recognised in IFC guidelines and is defined in the EU Landfill Directive such that “waste is considered inert if:

1. It does not undergo any significant physical, chemical or biological transformations;
2. It does not dissolve, burn or otherwise physically or chemically react, biodegrade or adversely affect other matter with which it comes into contact in a way likely to give rise to environmental pollution or harm to human health; and
3. Its total leachability and pollutant content and the ecotoxicity of its leachate are insignificant and, in particular, do not endanger the quality of any surface water or groundwater.”

In practice, inert waste typically comprises surplus excavated soil and rock, and waste construction materials such as brick and concrete.
Table 18.8 below presents a comparison of the FWCC hazardous waste classifications against IFC and EU classifications of hazardous, non-hazardous and inert waste.

**Table 18.8 Comparison of FWCC Hazard Codes with IFC and EU Classifications**

<td>Non-hazardous (but includes some hazardous categories, e.g. medical wastes)</td>
</tr>
<tr>
<td>Hazard Class V (slight hazard)</td>
<td>Unsorted ferrous steel scrap, unsorted aluminium scrap, unsorted kitchen and catering food waste, concrete products (grit), building grit, uncontaminated packaging waste (i.e. paper, cardboard and plastic of lost useful quality), glass cullet waste (excluding cathode ray tubes and luminescent lamps), non-treated wood waste, uncontaminated soil, construction debris of lost useful quality, etc.</td>
<td>Non-hazardous or inert</td>
</tr>
</tbody>
</table>
Suitable facilities are those which are licensed by the relevant regulatory authorities and (in the case of hazardous waste sites) are operating in accordance with GIIP \(^1\). The operational capabilities and licensing status of these facilities will be confirmed.

No specific waste study area was defined for the purpose of this chapter. Rather the assessment considered waste arising within the established Project Area boundaries and Associated Activities defined in **Chapter 1 Introduction** of this ESIA Report.

### 18.4 Project Wastes

The Project has the potential to give rise to a number of wastes during the Construction and Pre-Commissioning, Operational and Decommissioning phases.

The potential impacts arising from the management of wastes include:

- Impacts on human health and on ecological receptors from releases of waste to air, water or land; and
- Nuisance, including litter, odour, dust and vermin.

Impacts can arise throughout the waste management supply chain and therefore the generation, storage, collection and transport, reuse, recycling, recovery, treatment and disposal of waste are all taken into account when assessing impacts.

The impacts of wastes associated with the decommissioning phase of the Project have not been assessed in detail as the available waste facilities and disposal technologies are likely to change significantly over the 50 year life of the Project. For the decommissioning phase, the assessment is limited to identifying the types and approximate quantity of waste generated.

### 18.4.1 Wastes Arising from the Project

Generally, wastes can be categorised into three main types in terms of their basic properties:

- Inert waste - e.g. surplus excavated soil and rock, rubble and bricks;
- Non-hazardous waste - e.g. food waste, packaging waste and other general wastes from construction, businesses, industry and households; and
- Hazardous waste - e.g. oils, certain types of healthcare waste, batteries and other waste exhibiting hazardous properties.

Waste is considered to be inert if it does not undergo any significant physical, chemical or biological transformations; and does not dissolve, burn or otherwise physically or chemically react, biodegrade or adversely affect other matter with which it comes into contact in a way

\(^1\) In these cases, it is assumed that residual impacts due to releases from these facilities are addressed as part of the facilities pre-existing licensing regime and are therefore not assessed within this ESIA.
likely to give rise to environmental pollution or harm to human health\(^2\). Certain categories of municipal, industrial and construction waste (e.g. brick rubble) may be considered inert.

Individual jurisdictions typically have more detailed waste classification schemes. Table 18.8 above provides more specific details on the classification of waste based on the Russian FWCC.

The main types of waste expected to arise from the Construction and Pre-Commissioning Phase and Operational Phase of the Project are described below.

### 18.4.1.1 Construction and Pre-Commissioning

**Onshore**

The main landfall or onshore Pipeline Construction and Pre-Commissioning Phase works to be undertaken as part of the Project will comprise:

- Clearance and bulk earthworks associated with establishment of the Pipeline construction corridor;
- Trenching and installation of the Pipeline;
- Establishment of the microtunnels;
- Construction and installation of temporary construction sites;
- Construction of the landfall facilities; and
- Types and quantities of waste likely to be produced have been calculated and are presented (using the Russian FWCC codes) in Table 18.9. Further details are provided in the following paragraphs.

**Waste from Workforce**

Municipal waste will be primarily generated by construction workers operating across all of the identified activities and will be a function of the size of workforce. It will be generated from office operations and site welfare facilities (e.g. canteens, etc.). It is assumed that there will be no accommodation camps, and hence waste will only be generated by the workforce during the course of the working day.

This waste will comprise the following:

- Paper and cardboard;
- Glass;
- Biodegradable kitchen and canteen waste;
- Plastics;
- Metals (e.g. drinks cans); and

\(^2\) Article 2(e) of the EU Landfill Directive (1999/31/EC)
• General mixed waste.

In addition to the above, the Russian National EIA has calculated figures for the amount of waste textiles (i.e. protective clothing) and worn footwear that is anticipated to be produced during the onshore Construction and Pre-Commissioning Phase.

Waste from Construction Activities

Non-hazardous construction waste is likely to consist primarily of:
• Waste from vegetation clearance along the Pipeline construction corridor and landfill facility;
• Surplus excavated spoil from the Pipeline construction corridor and landfill facility;
• Material excavated from the microtunnelling operations;
• Packaging (paper, plastic, metal and wood) from construction materials received at the construction sites;
• Welding waste and metal swarf resulting from jointing of pipeline sections;
• Surplus, damaged and out-of-specification construction materials, including concrete and other inert materials; and
• Empty gas bottles and canisters.

During ground preparation works, excavated spoil will be generated by a number of construction activities. The preparation of the site for the construction of the landfall facilities, for example, will require extensive earthworks. A portion of excavated material will be reused (e.g. to prepare the development platform) and therefore will not be considered waste requiring disposal. Approximately 250,000 m³ (or 375,000 tonnes) of spoil is considered unusable and will be exported from the site.

A number of onshore temporary facilities will be required (e.g. for storage of pipe, equipment and materials; spoil storage areas; parking space; mess and welfare facilities, etc.). It is estimated that approximately 59 ha of land will be required for these facilities. The establishment of these temporary construction areas will involve the stripping of topsoil. Some areas of the construction corridor may also be benched or graded to eliminate irregularities, large stones, tree stumps and other features. The majority of this material will be temporarily stored and re-used for reinstatement.

The landfall section of the Project will use a combination of open-cut and trenchless techniques (i.e. microtunnelling) for pipeline construction. It will not be possible to return all the originally excavated trench spoil (due to the volume of space taken up by the installed pipelines and removal of rock or other unsuitable backfill material) and the surplus will either be disposed of or incorporated into landscaping activities.

The surplus excavation spoil from construction of the microtunnels and entry shafts will require incorporation into the works or off-site disposal.

Other construction wastes will include waste metal (e.g. from damaged pipe sections or as swarf from preparation of joints) and welding stubs. Waste cardboard packaging will mainly be generated from the cardboard packaging used for delivering welding electrodes.
Chapter 18 Waste Management

Following completion of pre-commissioning tests, temporary construction areas will be restored. This will include the removal of temporary roads and hardstanding (e.g. macadam base used in the temporary access roads) and a certain amount of uncontaminated waste sand and crushed stone will be produced.

Hazardous Waste

Hazardous wastes include those identified as either potentially harmful to human health or the environment, typically with the potential to lead to long term contamination. It is likely that the majority of these wastes will arise during the operation of construction vehicles, plant and equipment, and utilisation of potentially hazardous raw materials. The following hazardous wastes may be produced as a result of construction activities.

- Hazardous waste from maintenance of construction plant, including:
  - Oil filters;
  - Hydraulic oil;
  - Anti-freeze; and
  - Batteries.
- Sludge from cleaning out refuelling tanks;
- Packaging with residues of hazardous substances (e.g. paints, solvents or coatings);
- Fluorescent tubes;
- Oily residues or spent filters from surface water treatment system; and
- Clinical wastes from first aid facilities or on-site clinics.

A number of onshore temporary facilities will be required throughout the Construction and Pre-Commissioning Phase. These areas will be lit using various types of lighting and will most likely include the use of fluorescent tubes. Fluorescent tubes are categorised as extremely hazardous (Class I) by the FWCC.

The treatment of surface water runoff from the construction sites will give rise to a number of wastes (e.g. sludge or spent filters) potentially contaminated with oil that will require disposal.

Nearshore and Offshore Sections

The main activities which have the potential to generate waste within the nearshore and offshore sections during the Construction and Pre-Commissioning Phase are:

- Activities of pipe-lay vessels and regular deliveries of construction materials;
- Activities of dredging vessels and support craft;
- Assembly (mounting / joining / pulling) of the pipelines; and
- Activities of the crew involved in the operation of Project vessels and workers associated with the maintenance of the vessels.

Types and quantities of waste likely to be produced have been calculated and are summarised (using the Russian FWCC codes) in Table 18.10. Further details are provided in the following paragraphs.

Waste from Workforce

Municipal waste will be generated by construction workers and crew of all vessels and is categorised as ‘garbage’ under MARPOL Annex V. This type of waste will include general mixed waste, food waste and recyclable waste.

The workforce and crew aboard vessels will also generate sewage, which is regulated under MARPOL Annex IV.

Waste from Construction Activities

Dredging will generate a certain amount of dredged spoil. From the microtunnel exit point, the pipelines will be buried in trenches to a depth of approximately 2.5 to 3 m for a distance of approximately 170 m. The excavated material will be temporarily stored before being dredged back up and used as backfill following pipeline installation, and hence is not considered waste.

In addition to the above, there will be a requirement for some levelling and flattening of the seabed in the offshore section, prior to installation of the Pipeline. The resulting dredged material (estimated as 42,500 m³) will require disposal at a designated offshore disposal area.

Pipeline assembling activities will generate wastes associated with the jointing and installation of pipeline sections including stubs of welding electrodes, spent polishing bodies and metal swarf.

The construction materials and equipment used may require the disposal of associated packaging elements, typically a mixture of paper and cardboard, wood and plastic waste. Due to the scale of equipment used in the pipe-laying, some packaging waste items may be relatively large in dimension.

Hazardous Waste

A number of hazardous wastes may potentially be generated as a result of the nearshore and offshore Construction and Pre-Commissioning works, including:
• Waste oils and batteries from maintenance of construction plant;
• Oily waste generated during normal operation of the vessels undertaking the works (e.g. oily sludges and bilge oil);
• Waste fluorescent tubes and other lamps containing mercury from construction vessels; and
• Packaging with residues of hazardous substances.

Clinical wastes may also be generated from medical facilities on-board the vessels.

Oily wastes will be generated by vessels as a result of fuel filtering, collection of oily slops from machinery spaces, and from oily bilge water. Oily wastes generated by vessels are controlled under MARPOL Annex I. The discharge of any oily sludge or slops is prohibited. Bilge water may be discharged following treatment by an oily water separation (OWS) system, provided such discharge is in compliance with the requirements of MARPOL Annex I and Russian regulations. In practice, the requirement under MARPOL Annex I for vessels to be “proceeding en route” when they discharge treated bilge water may preclude pipe lay vessels from treating and discharging any bilge water, since they will be almost stationary whilst pipe laying. The oily residue following treatment of bilge water through an OWS will be managed in the same waste as oily sludge or slops.

Order No.20 of the Russian Federal Fishery Agency (dated 18 January 2010) mandates that discharges into Russian territorial waters must not lead to the limit 0.05 mg/L oil content being exceeded at the control point (which is typically 500 m from the point of discharge). Vessel OWS are generally designed to meet the MARPOL discharge requirements of 15 parts per million of oil (approximately equivalent to 12 mg/L) and it is unlikely that the discharge from a vessel’s OWS would result in non-compliance at the control point, due to the effect of dilution in the receiving water. There is therefore unlikely to be any constraints on the discharge of treated bilgewater over and above those outlined in MARPOL Annex I.

Discharge of hydro-testing and pipeline cleaning waters (during the Pre-Commissioning Phase) are discussed in Chapter 8 Soils, Groundwater and Surface Water. This process will require the use of monoethylene glycol (MEG) as a drying agent. Waste MEG will be collected and stored in tanks on support vessels prior to onshore disposal.

18.4.1.2 Operational Phase

In comparison to the Construction and Pre-Commissioning Phase, it is anticipated that the Operational Phase of the Project will generate much smaller volumes of waste. As the Pipeline will carry dry gas, there is not expected to be any accumulation of scale or need for frequent cleaning.

Types and quantities of waste likely to be produced have been calculated and are presented (using the Russian FWCC codes) in Table 18.11. Further details are provided below.

Onshore

No waste will be routinely produced at the Landfall Facilities during normal operating conditions; they will be unmanned.

A very small amount of waste will be produced by staff undertaking maintenance activities (inspections, surveys, etc.). The Pipeline Right of Way (RoW) will be kept clear of deep-rooting trees by periodic inspection and clearance. This is not anticipated to give rise to any wastes that would require off-site management or disposal.

A small number of fluorescent tubes will require replacing each year at the Landfall Facilities during the Operational Phase of the Project. The treatment of surface water runoff from the permanent Landfall Facilities will give rise to a number of wastes (e.g. sludge or spent filters) potentially contaminated with oil that will require disposal.

Waste filters and waste lubricating oil will also be produced as a result of the routine maintenance of plant and machinery (but very low volumes are expected).

Nearshore and Offshore Sections

Normal operation of the Pipeline will not generate waste in the nearshore and offshore sections. Surveys will be carried out of critical areas on an annual basis using Remotely Operated Vehicles (ROV), and of the whole Pipeline every five years. These surveys will be carried out from vessels and the survey duration is expected to be five days for annual surveys and up to 30 days for the five-year surveys. The survey vessels will generate relatively small quantities of MARPOL Annex V (garbage) and MARPOL Annex I (oily waste).

In the event of emergency pipeline repair, vessels will need to be mobilised and welding may be required. The types of waste would be similar to those generated during construction, but since the frequency and severity of pipeline repair cannot be estimated, there is no information on the quantities of waste arising. Since the probability of failure is expected to be low, the likelihood of significant quantities of repair waste being generated is also expected to be low.

18.4.1.3 Decommissioning

The expected service lifetime of the South Stream Offshore Pipeline is 50 years. Decommissioning of the Pipeline will be undertaken in accordance with the legislation prevailing at that time, in liaison with the relevant regulatory authorities.

Within the South Stream Offshore Pipeline timeframe of 50 years there may be changes to statutory decommissioning requirements, as well as advances in technology and knowledge. South Stream Transport will therefore utilise GIIP during all decommissioning activities.

The actual method used for decommissioning will not be determined until closer to the time of decommissioning, and in particular, no decision has been made on whether the subsea pipelines will be removed, or whether they will be decommissioned in situ (i.e. flushed, filled with water, sealed and left in position).

The main waste materials generated by decommissioning will be inert crushed stone (from demolition of structures and removal of hardstanding) and metal (from pipes and ancillary equipment). Depending on the techniques used, small quantities of waste associated with maintenance of the plant used for decommissioning may also be generated.

18.5 Mitigation Measures

18.5.1 General Approach to Waste Management

The general approach to managing solid waste will be described in the integrated Waste Management Plan (WMP) drawn up by contractors. This provides guidance on:

- Waste minimisation and prevention;
- Identification and segregation of waste materials at source;
- Recycling and reuse of suitable materials; and
- Treatment and disposal of specific waste streams.

The integrated WMP will refer to vessel-specific Waste Management Plans which will include provisions for segregating waste on board, having secure areas for storage of hazardous waste and recycling or reuse where practicable.

The structure of the waste management elements of integrated WMP should follow the outline provided in Table 18.13.

All wastes will be managed in accordance with the applicable regulations and statutory obligations.

18.5.2 General Mitigation Measures

The general approach to mitigating impacts will be to use existing licensed facilities which comply with Russian regulations and the requirements of the IFC EHS Guidelines and Performance Standards. Prior to the start of construction works, contracts will be arranged with licensed organisations for the transport, reuse, recycling, treatment and final disposal of waste.

Pursuant to Article 19 of Federal Law № 89-FZ of 24 June 1998 (“On Production and Consumption Wastes”), waste producers are obligated to keep proper records of the wastes generated, treated, and handed over to other parties.

Waste recordkeeping shall be conducted in the locations where the wastes are generated, used, and treated, and also when transferring the wastes for recovery during the construction period. A designated Waste Control Officer will be responsible for keeping records on the wastes generated. The Waste Control Officer shall record this information, in the manner required by Order № 721 of 01 September 2011 (“On Approval of the Waste Management Recordkeeping Procedure”), in specially created tables that are used as the primary means of tracking waste transfer. The results presented in the tables will be used to fill out government statistical reports (№2-TP Wastes), and must also be used in the Adverse Environmental Impact Fee Calculations.

All personnel will receive a briefing on the waste management rules and principles whilst working onsite.

Temporary waste storage sites will meet the following requirements:

- Ensure that impacts on the environment are avoided or minimised as far as practicable;
- Ensure that there is no risk to human health as a result of hazardous waste;
Prevent the loss of properties of recycled waste as a result of improper collection and storage;

Minimise the risk of fire from stored waste;

Prevent littering;

Undertake a waste inventory and monitor waste management; and

Ensure ease of waste disposal.

Appropriate skips, containers, bags and storage areas will be provided including the separate storage of hazardous and non-hazardous wastes and for the segregation, where viable, of materials suitable for reuse or recycling such as metals and plastics.

Transportation of waste will be carried out in compliance with environmental safety regulations, ensuring protection of the environment when handling loading and unloading operations and transportation. The Project will comply with the following requirements regarding transportation of wastes:

- Transportation of hazard Class IV or V wastes to industrial waste landfill will be carried out by specialised transport vehicles;
- Operations associated with loading, transportation and unloading of waste are mechanised where practicable, in order to avoid possible losses en route and environmental pollution;
- Each type of waste is subject to separate transportation so that wastes will not be mixed during transportation;
- All vehicles delivering waste will be accompanied by a consignment note which will be signed by the responsible person; and
- Once the waste has been delivered, the transport vehicles and containers that were used will be cleaned in a specially designated location.

The frequency of waste collections destined for the permanent disposal facilities (landfill) or recycling facilities will be determined by the following factors:

- Frequency of waste accumulation;
- Availability and capacity of the vessel (container) on site for temporary storage of waste; and
- Type and hazard class of the waste stream and its compatibility with other waste streams during storage and transportation.

### 18.5.3 Specific Mitigation Measures

The specific mitigation measures that will be adopted to ensure responsible management of the wastes arising from the Project are described below and summarised in Table 18.14.
18.5.3.1 Onshore

Waste from Workforce

All wastes arising will be stored, collected and transported off site in appropriate bins and containers. Only appropriately licensed companies will be employed for the transportation, recycling and disposal of waste. All waste will be managed using existing local facilities which are suitably licensed under Russian regulations.

During operation, the small quantities of waste generated will typically be transported back to the base office of the staff involved, from where it will be managed using local waste collection and disposal companies.

Waste from Construction Activities

Construction waste will be segregated at source and collected by suitably licensed local waste management contractors for recycling or disposal using existing local facilities which are suitably licensed under Russian Federation regulations.

It is considered that a portion of the waste generated within the Construction Phase has an opportunity to be reused or recycled. Examples include:

- Recycling of inert wastes, excavated materials and surplus concrete and concrete products into aggregates for use within the development, such as in parking areas or access roads;
- Recycling of metal off-cuts, surplus and damaged parts, including pipework, re-bar, cabling etc.; and
- Reuse, recycling or recovery of packaging wastes including wood, cardboard, paper and some plastics.

Where possible, contractors will be encouraged to reduce waste arisings and identify opportunities for reuse and recycling.

The location of waste storage areas will consider the nature of the materials to be stored within, the likelihood of disturbance through accidents, and control actions available in case of emergency (e.g. fire, flood).

General construction wastes will be managed with a local waste management contractor as per the local waste management market. The waste management contractor will be approved by Russian regulatory authorities to transport, reuse, recycle, treat and/or dispose of waste types that are generated. Appropriate skips, containers, bags and storage areas will be provided including the separate storage of hazardous and non-hazardous wastes and for the segregation, where viable, of materials suitable for reuse or recycling such as metals, plastics and paper and card.

As far as possible, surplus excavated spoil will be used for landscaping purposes within the construction corridor or will be used for site engineering or restoration purposes at a local landfill site, or as inert backfill at identified quarries.
**Hazardous Waste**

Hazardous materials, such as waste oils and oily wastes, will be contained in appropriate closed containers and drums. Liquid wastes will be stored in an area of secondary containment, designed to capture any waste that may leak from the containers, with a volume equal to at least 110% of the volume of the largest storage container. Hazardous wastes will be collected for treatment by a suitably licensed waste collector and treated at a facility which complies with the relevant local regulations and GIIP.

Waste fluorescent tubes will be stored separately in a designated container which is resistant to chemical degradation and prohibits accumulation of water. Transportation of such waste will be undertaken in accordance with strict guidelines to ensure integrity and eliminate the possibility of contamination of the environment. Waste fluorescent tubes will not be stored outdoors, in cardboard boxes, or on the ground, and will be removed at least every three months regardless of the amount accumulated.

Any small quantities of medical waste generated will be temporarily stored in fit-for-purpose containers in a closed room with restricted access for the staff until transport off site by an approved and licensed contractor to a dedicated clinical waste management facility.

**18.5.3.2 Offshore**

**Waste from Workforce and Construction Activities**

Offshore waste during both construction and operation will be managed in accordance with the requirements of MARPOL 73/78.

With respect to MARPOL Annex V waste, there will be no discharge of any garbage within 12 nautical miles of the coast. Outside this 12 nautical mile limit, food waste may be comminuted or ground prior to discharge, providing vessels are en route. MARPOL Annex V does not give any minimum speed as part of the definition of “en route”.

Garbage will be stored on vessels in suitable containers, clearly marked to indicate the type of waste within. Any garbage requiring transfer either to support vessels or for onshore disposal will be located in order to provide ease of access for loading and unloading. Once the waste has been transferred to shore, it will be collected by the port authorities or their nominated contractors using the existing port waste reception facilities.

Alternatively, if equipped, vessels may make use of on-board garbage incineration units, provided these are type approved in accordance with the IMO “Standard Specification for Shipboard Incinerators” and comply with the requirements of Regulation 16 of MARPOL Annex VI and the Standard Specification for On-board Ship Incinerators, adopted by the Marine Environment Protection Committee on 25 September 1997 (Ref. 18.27). On vessels capable of incineration the following solid wastes may be incinerated: domestic waste (excluding glass); operating wastes (e.g. oily sludges); textiles; and uncontaminated plastic containers. Solid wastes that will not be incinerated include mercury vapour lamps and mercury-containing fluorescent tubes, glass and scrap metal.
There will be no inappropriate mixing of waste types (e.g. domestic waste with hazard Class 1 or 2 waste) and containers will be not overfilled. Where feasible, recyclable garbage (e.g. glass and plastics) will be separated at source, separately stored and collected for recycling by the port waste reception contractors. Domestic waste containing a high biodegradable fraction will not be stored for more than one week (reduced to two days in the summer).

Where waste is transferred to other ships, specific procedures will govern methods employed for preparing material and ensuring accidental discharge, spillages or leaks do not occur. Consignment notes detailing the quantity and type of waste transferred between ships will be kept.

Project vessels shall carry a Garbage Management Plan which will include written procedures for collection, storage, processing and disposal of waste, including the use of any relevant equipment fitted onboard. The Garbage Management Plan will designate the person responsible for carrying out the Plan. Vessels over 400 gross tonnage or carrying more than 15 passengers shall also maintain a Garbage Book.

For the purposes of complying with MARPOL 73/78, construction waste arising on board the vessels will be managed as MARPOL Annex V waste, with discharge at sea strictly prohibited. All waste (predominantly welding and packaging waste) will be retained on board, source-separated where practicable, and collected by the port authorities or their nominated contractors using the existing port waste reception facilities. Any hazardous waste generated during offshore construction (other than MARPOL Annex I Oily Waste, described separately below) will be stored, collected and managed separately in accordance with Russian regulations.

The Project will generate dredged spoil from offshore trenching and profiling. Dredged spoil in the nearshore zone (i.e. from microtunnelling activities) will be temporarily stored in designated offshore storage areas. This material will be subsequently re-dredged and used for trench backfill following pipe installation. A certain amount of offshore dredged material (estimated volume of 42,500 m³) will be disposed of at an existing underwater disposal site (no. 923, located on the Russian continental slope).

In the event that any dredge spoil is identified as contaminated or requires disposal on land, the spoil will be treated as construction waste and appropriately stored, transported and disposed of. However, baseline studies undertaken to date do not indicate that this is likely.

Sewage from vessels will be managed in accordance with MARPOL Annex IV. Discharge of sewage will only take place when:

- The ship is discharging comminuted and disinfected sewage at a distance of more than 3 nautical miles from the nearest land, or sewage which is not comminuted or disinfected at a distance of more than 12 nautical miles from the nearest land, provided that in any case, the sewage that has been stored in holding tanks shall not be discharged instantaneously but at a moderate rate when the ship is en route and proceeding at not less than 4 knots; or

- The ship has in operation an approved sewage treatment and the effluent does not produce visible floating solids nor cause discoloration of the surrounding water.
Hazardous Waste

Under MARPOL Annex I, vessels are permitted to discharge bilge water which has been treated using an Oily Water Separater (OWS) such that it has oil content below 15 ppm, provided the vessel is proceeding en route. "En route" for the purposes of MARPOL Annex I is defined as meaning "... that the ship is underway at sea on a course or courses, including deviation from the shortest direct route, which as far as practicable for navigation purposes, will cause any discharge to be spread over as great an area of the sea as is reasonable and practicable". Vessels which are stationary (i.e. not en route) will be required to retain bilge water on board for subsequent discharge to dedicated collection vessels; or treatment and discharge once they are proceeding en route; or discharge to port waste reception facilities.

Oily sludge will be collected and stored in dedicated sludge tanks. Oily sludge (and residues from bilge water OWS systems) will be treated by incineration in the case of those vessels having MARPOL-compliant incinerators. In all other cases, oily wastes will be retained on board for subsequent discharge to dedicated collection vessels or port waste reception facilities.

Vessels will maintain an Oil Record Book and Oil Pollution Emergency Plan in accordance with MARPOL Annex I.

MEG from the hydrotest and dewatering operation of the nearshore section will be collected and stored on board vessels and transported to a suitable facility onshore for recycling. Depending on whether MEG will be transported on board the vessel in packaged form or in bulk (i.e. whether it will be stored in demountable tanks on a regular vessel, or in internal tanks in chemical tanker), it may be regulated by either MARPOL Annex III (Regulations for the Prevention of Pollution by Harmful Substances Carried by Sea in Packaged Form) or Annex II (Regulations for the Prevention of Pollution by Noxious Liquid Substances in Bulk), and the vessel will comply with the relevant provisions.

MEG is categorised as a potential marine pollutant under the International Maritime Organisation's International Maritime Dangerous Goods (IMDG) Code and as such must be suitably packaged and labeled in accordance with MARPOL Annex III. Under MARPOL Annex II, MEG is classified as a Category Y pollutant.

18.5.3.3 Summary

Table 18.14 summarises the management measures proposed for the various waste types anticipated to be generated by the Project and facilities which may be used for the intermediate storage, treatment and/or disposal of the wastes.

Due to the long period of time before decommissioning is programmed to start, it is not possible to identify specific management routes and facilities for decommissioning waste. However, the great majority of decommissioning waste will be inert rubble or metal.

**18.5.4 Monitoring**

South Stream Transport will develop a detailed overarching Environmental and Social Monitoring Programme that will detail the monitoring requirements. As part of this ESMP, the quantities of waste generated by the project and the means of management of these wastes will be monitored on a regular basis. Monitoring will also be carried out to ensure compliance with Russian regulations, as described in Section 18.5.2 above, and MARPOL requirements for...
maintenance of Oil and Garbage Record Books as required under MARPOL Annex I and V respectively.

Monitoring records will be maintained which will include, as a minimum, the following information:

- Types and quantities of waste generated;
- Types and quantities of waste leaving Project sites or vessels for recycling, recovery or disposal;
- Details of vehicles or vessels transporting waste from the sites;
- Location of treatment or disposal facilities to which the waste is transported; and
- Records of any spillages or unplanned releases, or any enforcement actions.

**18.5.5 Assessment of Residual Impact Significance**

Table 18.15 indicates the assessed residual impact significance of each waste stream assuming management measures as described are implemented.

The main regional landfill site (Alfa landfill) is not designed or operated as an engineered landfill in accordance with GIIP, and hence this has been identified as being a potentially unsuitable facility. However, the wastes that require landfill disposal are non-hazardous and relatively small in quantity (typically less than 1000 tonnes per waste stream). Alfa landfill is due to be replaced once it ceases operation in 2016, and thereafter the replacement landfill would be used by the Project, which is expected to be an engineered facility (although its location is yet to be confirmed by the local government). In the event that any Project wastes are deposited at Alfa landfill, the impacts are not expected to be significant since the wastes are non-hazardous, and those wastes arising from the Project would form only a very small proportion of the overall waste disposed of at Alfa, such that they would not significantly increase any existing environmental impacts associated with the site.

The overall quantities of waste requiring management are relatively small in comparison with the capacity of the receiving facilities. Any impacts from accidental release during temporary storage or transport of hazardous wastes will be minimised by implementing an integrated WMP.

* The current status of Alfa Landfill is discussed in Table 18.6 and the potential use of this facility for non-hazardous wastes is discussed in Section 18.8 below.

18.6 Unplanned Events

Procedures for dealing with unplanned events will be set out in the Project Emergency Preparedness and Response Plan (see Chapter 22 Environmental and Social Management). The mitigation measures described in this chapter (including the procedures for temporary storage and transportation of waste) have been developed with the intention of mitigating the likelihood of any unplanned release of wastes; for example, releases due to
inadequate storage arrangements at the site, or spillages during loading and unloading of wastes, and the Project Emergency Preparedness and Response Plan will include contingency arrangements in the unlikely event of releases (e.g. provision of spill kits).

18.7 Cumulative Impacts

There are four known developments in the region which are all onshore. The Russkaya compressor station (CS) is considered to be the most significant of these which may add pressure on waste storage and disposal facilities in the area. However, providing all wastes are disposed of in accordance with legislative requirements at waste facilities operating in accordance with permitted conditions and GIIP, the Project will not generate significant cumulative impacts. The quantities of hazardous and non-hazardous waste arisings from the Project are small when compared to total regional arisings and therefore no significant cumulative impact is expected. Although large quantities of uncontaminated soil and rock will be generated, this is not expected to give rise to significant cumulative impacts since it will be used for backfill or restoration purposes at quarry or landfill sites in the region; and since the material is inert, it is unlikely to give rise to significant environmental impacts.

Cumulative impacts are considered and assessed in Chapter 20 Cumulative Impact Assessment.

18.8 Conclusions

The assessment of waste management impacts arising from the Project has identified the waste streams that are anticipated to be produced during the Construction and Pre-Commissioning Phase and the Operational Phase and identified the availability and suitability of existing waste management facilities to manage those wastes. Mitigation measures have been recommended in order to minimise the impacts as far as possible, including the preparation and implementation of an integrated WMP by contractors.

Moderate impacts are estimated in the event that the existing Alfa landfill are to be used for disposal of non-hazardous wastes from the Project. It is expected that this landfill will be closed and a replacement engineered facility may be available by 2016. Even in the absence of such a facility, the relatively small amounts of non-hazardous waste requiring landfill means that the impacts of using Alfa Landfill would not be significant.

Provided that all of the mitigation measures described above are correctly implemented, the overall waste management impacts from the development are expected to be Not Significant.

19 Unplanned Events

19.1 Introduction

Unplanned events are episodes that are not expected to occur during the Project’s normal Construction and Operational Phase activities, such as accidents. The Project follows safety and engineering design criteria that aim to avoid unplanned events that could lead to adverse environmental, socio-economic or health and safety impacts.

This chapter provides an assessment of the potential environmental and socio-economic risks and impacts from onshore and offshore unplanned events, that could occur during the Construction and Pre-Commissioning, Operational (including Commissioning) Phases of the Project so that design controls and mitigation measures can be put in place. The approach to unplanned event management during the Decommissioning Phase is also presented herein. Project risks and impacts associated with worker occupational health and safety (OH&S) are considered in Appendix 15.1: Occupational Health and Safety.

The assessment considers both the likelihood of unplanned event occurrence as well as the potential consequences of such events.

19.2 Scope and Approach

The overall Project Area (the geographical area within which all proposed Project Activities will occur as defined in Chapter 1 Introduction) has been split into three main areas of activity for the purpose of the assessment of unplanned events, namely:

- Onshore Landfall: Area covers all Project onshore landfall facilities and activities (from the landfall facilities of the Project to the shoreline); and
- Offshore: Area includes the nearshore and offshore sections as defined in the previous chapters of this ESIA Report. This area commences at the shoreline and extends out to the border of the Russian and Turkish Exclusive Economic Zones (EEZ) in the Black Sea.

Locations in the wider surrounding area and/or between these main areas of activity that could be affected by unplanned events are also considered. For example, onshore access roads / routes and shipping routes.

This chapter focuses on those unplanned events considered to be of most relevance to the Project given the nature of the construction activities, the operational requirements of the pipelines and the geographic location of the Project. In order to assist the unplanned event identification process, South Stream Transport has undertaken an Emergency Threat Analysis for the Project that determines the risks posed by potential emergencies and the need for an Emergency Preparedness and Response Plan and related procedures as a contingency for

\[1\] Involves use of an emergency risk analysis spreadsheet that assigns risk ratings against potential unplanned events taking account of event likelihood and consequences. In August 2013 South Stream Transport undertook an internal Emergency Threat Analysis workshop involving relevant specialists.
emergency events. The unplanned events considered within this chapter have been identified via the Emergency Threat Analysis.

Where available, information on the likelihood of occurrence of unplanned events has been drawn from statistics from industry organisations. Data on the frequency of shipping incidents has been taken from statistics published by recognised industry bodies, including the International Association of Oil & Gas Producers and the European Maritime Safety Agency.

Given the inherent uncertain nature of potential unplanned events, the potential variability of such events in terms of geographic location and coverage, and limitations of directly relevant event statistics, a qualitative assessment methodology has been adopted herein. This methodology has entailed the following tasks:

- Screening of unplanned events to identify those which are carried forward for further consideration;
- Identifying the range of activities that could lead to the occurrence of a potential unplanned event during Construction and Pre-Commissioning and the Operational (including Commissioning) Phases of the Project;
- If possible, determining the likelihood of occurrence of such events;
- Defining and describing the geographic range of occurrence of potential unplanned events;
- For each unplanned event, definition of the potential resultant impacts in relation to potentially affected receptors; and
- Definition of appropriate risk management measures to reduce the likelihood of occurrence of each unplanned event and minimise the residual significance of any resulting impacts.

When determining the potential consequences of unplanned events, the resultant impacts have been assessed in relation to categories of receptors as follows:

- Environmental receptors; and
- Socio-economic receptors (including impacts upon community health).

OH & S impacts associated with unplanned events are not considered in this chapter. However, South Stream Transport will implement internationally recognised procedures to assure the OH&S of the workforce (including during unplanned events) along with the necessary equipment and training to make these effective. OH&S measures will be included in a Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS) which will form an important part of the corporate management system (Chapter 22 Environmental and Social Management).

In order to support the unplanned events assessment as reported herein, the following additional assessments have been undertaken:

- Quantitative Risk Assessment (QRA) (Ref. 19.1 and Appendix 19.1: Quantitative Risk Assessment) which considers the risks to the public as associated with the operation and maintenance of the onshore pipeline and landfall infrastructure and facilities;
• Maritime Risk Assessment (Appendix 19.2: Maritime Risk Assessment and Oil Spill Modelling) which considers the risks of marine vessel accidents occurring and the potential for consequential oil spillages;

• Oil spill modelling (Appendix 19.2) to investigate the fate and behaviour of various oil spill scenarios that may occur following an unplanned marine event (as identified by the maritime risk assessment); and

• Terrestrial and marine geohazard evaluation (Appendix 19.3: Unplanned Events - Marine Geohazards) which highlights the potential geohazards present along the pipeline alignment, and the actions that have been undertaken to manage risks to pipeline integrity.

19.3 Legal Context

A range of legislation has been passed in Russia that requires plans and actions to be developed should unplanned events have the potential to impact on workers, the local community and the environment. Much of the legislation applies to private organisations as well as public authorities and local government bodies. This legislation reinforces the prevention and elimination of accidents and promulgates the need for emergency and management plans and thus the legislation needs to be taken into account as part of the Project’s unplanned event risk minimisation and management process. A summary of the relevant legislation is outlined below:

• Russian Federation Law “On protection of population and territories from natural and man-made emergency situations”, No. 68-FZ, 21 December 1994: The law sets forth institutional and legal provisions for the protection of people, land, water and air space from emergency situations. This Federal Law extends to public authorities, local government bodies, as well as to private companies and organizations;

• Russian Federation Law “On fire safety”, No. 69-FZ, 21 December 1994: The law determines legal, economic and social basis for provision of fire safety in the Russian Federation, regulates relations between the state authorities, self-government bodies, institutions, private organizations, other legal entities and also between public organisations, officials, citizens of the Russian Federation, foreign citizens, and stateless persons;

• Russian Federation Government Enactment “On procedure for organising measures for emergency oil spills’ prevention and response in the territory of the Russian Federation”, No. 240, 21 August 2000: The resolution determines the main requirements for developing plans for emergency oil spill prevention and response. The requirements define the principles for formulation of the plans for emergency oil spill prevention and response, which apply to emergency situations of onsite, local, territorial, regional and federal importance, and coordination of response measures;

• Russian Federation Government Enactment “On urgent measures for emergency oil spills’ prevention and response”, No. 643, 15 April 2002: The related rules establish requirements for organising measures for emergency oil spill prevention and response aimed at reducing adverse impacts on humans and the natural environment. The measures are organised by the federal bodies of executive power of the Russian Federation, self-government bodies and companies who carry out field exploration, oil production, refining, transportation and storage of oil and related products; and
• Russian Federation Requirements “On adoption of requirements for prevention of emergency situations at potentially hazardous facilities and vital infrastructure”, No. 105, 28 February 2003: The requirements provide a set of measures on reduction of risk of emergency situations of technogenic character at potentially hazardous facilities, which use, produce, process, store and transport fire-explosion-hazardous substances, hazardous chemical and biological substances, including the provision of publicly vital activities (water supply and wastewater discharge, waste water treatment, heat and power supply utilities, hydro-engineering facilities). The specified requirements are as follows:
  o Identification of emergency situations for population and territories, coordination and planning for monitoring, forecasting and modelling, zoning of Russian territories by location of hazardous production facilities;
  o Classification of potentially hazardous facilities and vital infrastructure by risk of emergency situation occurrence at these facilities;
  o Design, construction, operation and decommissioning of facilities, which are hazardous to the population and Russian territories;
  o Management of actions for emergency situation prevention and protection of population and territories from hazardous impacts; and
  o Assessment of potentially hazardous facilities preparedness to emergency situation prevention and sufficiency of measures for protection of population and territories.

19.4 **IFC Requirements and Guidance**

International Finance Corporation (IFC) Performance Standard (PS) 1 Assessment and Management of Environmental and Social Risks and Impacts (January 1, 2012) (Ref. 19.11) states that:

"The client, in coordination with other responsible government agencies and third parties as appropriate will conduct a process of environmental and social assessment, and establish and maintain an ESMS appropriate to the nature and scale of the project and commensurate with the level of its environmental and social risks and impacts. The ESMS will incorporate the following elements: (i) policy; (ii) identification of risks and impacts; (iii) management programs; (iv) organizational capacity and competency; (v) emergency preparedness and response; (vi) stakeholder engagement; and (vii) monitoring and review."

PS1 goes on to highlight the need for the Environmental and Social Management System (ESMS) to establish and maintain an emergency preparedness and response system:

"...so that the client, in collaboration with appropriate and relevant third parties, will be prepared to respond to accidental and emergency situations associated with the project in a manner appropriate to prevent and mitigate any harm to people and/or the environment. This preparation will include the identification of areas where accidents and emergency situations may occur, communities and individuals that may be impacted, response procedures, provision of equipment and resources, designation of responsibilities, communication, including that with potentially Affected Communities and periodic training to ensure effective response. The emergency preparedness and response activities will be periodically reviewed and revised, as necessary, to reflect changing conditions."
Guidance on the content and coverage of Emergency Preparedness and Response Plans is provided in the IFC Environmental, Health and Safety (EHS) Guidelines (IFC, 2012) (Ref. 19.12). Also of relevance is PS4 Community Health, Safety, and Security (Ref. 19.15) which addresses the client’s responsibility to avoid or minimise the risks and impacts to community health, safety, and security that may arise from project related-activities, with particular attention to vulnerable groups. PS4 states that:

“In addition to the emergency preparedness and response requirements described in Performance Standard 1, the client will also assist and collaborate with the Affected Communities, local government agencies, and other relevant parties, in their preparations to respond effectively to emergency situations, especially when their participation and collaboration are necessary to respond to such emergency situations. If local government agencies have little or no capacity to respond effectively, the client will play an active role in preparing for and responding to emergencies associated with the project. The client will document its emergency preparedness and response activities, resources, and responsibilities, and will disclose appropriate information to Affected Communities, relevant government agencies, or other relevant parties.”

19.5 Emergency Preparedness and Response Plan

Chapter 22 Environmental and Social Management highlights that South Stream Transport will prepare an over-arching Emergency Preparedness and Response Plan for the overall project (covering Russian, Turkish and Bulgarian sectors) in line with IFC EHS Guidelines. The plan will be part of the HSSE-IMS as defined in Chapter 22 Environmental and Social Management.

This plan will define response actions for material unplanned events / risks that have been identified by the Emergency Threat Analysis. The overarching plan will cover all project phases and will include details as suggested by the IFC EHS Guidelines as follows:

- Purpose and scope;
- Emergency response management strategy;
- Emergency risk analysis, Emergency Preparedness and Response Plan and definition of the relationships with Contractors’ Emergency Response Plans;
- Roles and responsibilities;
- Communication requirements;
- Emergency drill requirements (including examinations, inspections and testing); and
- Review processes.

South Stream Transport’s Construction Contractors will be responsible for preparing their own Emergency Response Plans for their work activities, and specifically those events identified by the Emergency Threat Analysis. Contractors are expected to apply Good International Industry Practices (GIIP) and applicable recognized industry standards when preparing their Emergency Response Plans.
Chapter 19 Unplanned Events

The preparation of contractors’ Emergency Response Plans will be a requirement of the applicable works Contract, and will be available prior to the start of construction activities and will be subject to South Stream Transport review and acceptance. South Stream Transport will ensure that Contractors’ plans are integrated with other Project response plans, including South Stream Transport’s overarching Emergency Preparedness and Response Plan.

Similarly, South Stream Transport will ensure that contractor Emergency Response Plans appropriately integrate with the Emergency Prevention and Response Plan for Anapa municipality and the National Disaster Management Plan with regard to command and control systems, points of first contact during emergencies, local capabilities and capacity.

South Stream Transport will also prepare a Security Plan which will include the following:

- Systematic identification of security threats;
- Monitoring of social and other conditions related to security threats;
- Security screening of employees and other persons, as appropriate;
- Security measures to protect the property, assets, employees and intellectual capital of South Stream Transport;
- Information, instruction and training on security practices and requirements;
- Promotion of personal and corporate security;
- Security surveillance, including CCTV, security guards etc.;
- Emergency response plan and crisis management plan in case of serious security incidents; and
- Analysis of security incidents to facilitate lessons learned.

The Security Plan will be coordinated with the contractors who will be required to demonstrate how they will ensure compliance with the plan through the development of their own contract-specific Security Plan and procedures.

As detailed in Section 14.8.6 Security Provision (Chapter 14 Socio-Economics), in order to ensure there are no risks of human rights abuses against local communities by security forces, whether these be directly employed by the Project, contractors or state security forces, South Stream Transport will ensure training for security forces on escalation of force and protection of human rights. Furthermore, South Stream Transport will use its contractual process to ensure that provisions are in place for the conducting of background checks on security staff, as well as monitoring of performance.

The security provisions for the Project will follow the guidance as set forth in the Voluntary Principles on Security and Human Rights (Ref. 19.14). Policies, plans and procedures to protect the safety and security of the workforce, community and other Project stakeholders will be documented in the HSSE-IMS (Chapter 22 Environmental and Social Management). Figure 19.1 illustrates the relationship between South Stream Transport's over-arching Emergency Preparedness and Response Plan and the contractor Emergency Response Plans for the onshore and offshore areas, as well as external agencies and associated emergency plans.
19.6 Onshore Landfall Section

19.6.1 Construction and Pre-Commissioning Phase – Landfall Section

19.6.1.1 Events Identification

During the Construction and Pre-Commissioning Phase of the Project, unplanned events in the onshore landfall section may occur as a result of the use of construction plant, power generation equipment and from vehicular traffic in conjunction with equipment malfunction or human error.

Table 19.1 lists the activities that could result in an unplanned event, a description of the unplanned event, and the receptors which could be affected.

The design controls that will be put in place to reduce the likelihood of occurrence of the above potential unplanned events, as well as the mitigation / response measures that will be enforced to minimise the consequences associated with these events, are discussed below.

19.6.1.2 Potential Impacts to Environmental Receptors

Fuel and Oil Spillages

Construction activities will require many large mobile plant items (e.g. excavators, dozers), power generation equipment and vehicles that will be powered by diesel oil and which will contain relatively small reservoirs of lubricant oil and hydraulic oil. There is the potential for environmental damage if such materials are spilled depending on the volume and location of the spill / loss of containment.

Oil spilled to unpaved areas could potentially seep into the soil if the spill is not responded to immediately. Small oil spillages to paved and contained areas can generally be responded to in a manner that does not impact upon environmental receptors (unless spillages to paved areas subsequently discharge onto unpaved areas). In the case of a relatively large spillage of fuel,
associated for example with a fuel tank rupture as a result of vehicular accidents, the spilled fuel could also discharge directly into any nearby drainage ditches or watercourses.

Such a spill of diesel fuel, lubricants or hydraulic oil impacting upon surface water could be harmful to aquatic organisms and may cause long-term adverse effects in the aquatic environment. Spillages to soil could also result in localised soil contamination.

Most onshore construction related oil spillage incidents are likely to be relatively small (e.g. less than 100 litres) given the nature of the vehicles / mobile plant being used. The control measures to be adopted by the Project will be defined within a Spill Prevention and Response Plan which will be developed and maintained by each Project contractor. The Spill Prevention and Response Plan will include aspects such as the following:

- Introduction and objectives;
- Roles and responsibilities;
- Oil spillage risk analysis;
- Response equipment details;
- Response actions;
- Communication requirements;
- Drill and training requirements; and
- Review processes.

The application of the Spill Prevention and Response Plan will reduce the risks of any long-term significant adverse impacts on the aquatic environment as a result of such events. In the case of soil contamination from a small scale spillage, in accordance with the Spill Prevention and Response Plan, any contaminated soil would be promptly removed and disposed of at an appropriately licenced waste management facility. Such actions taken will reduce the risks of any long-term significant adverse impacts on soil quality. Given the small quantity of any accidental hydrocarbon spillages and implementation of the Spill Prevention and Response Plan, the potential for adverse impacts upon groundwater resources will also be reduced. Any residual groundwater contamination will only be locally affected and is expected to gradually recover through natural attenuation (Section 8.6.2).

Accidents during the bulk transportation of fuel to the landfall section and spillages from bulk fuel storage tanks (e.g. tank rupture or as a result of human error or equipment malfunction during tank loading and unloading operations) could result in a large spillage of hydrocarbon (greater than 100 litres) into the environment. The design controls that will be implemented to minimise the risks of such events occurring and to prevent adverse environmental impacts will be included in the Spill Prevention and Response Plan. Measures include:

- Appropriate driver training;
- The use of designated routes for transporting fuel to the landfall site (avoiding where possible environmental sensitive areas and built up areas);
- Definition of spillage containment equipment and clean-up actions following such events; and
Chapter 19 Unplanned Events

- Provision of on-site secondary containment facilities for all hydrocarbon storage tanks (including loading and unloading bays) to enable any spillages of hydrocarbons to be contained, thus preventing significant environmental impacts.

Fires

Fires during construction could occur, for example, as a result of the accidental ignition of dry vegetation during certain operations that involve the use of gas torches (hot works), such as heat wrapping of the coating that is applied to the pipe welds or during torch welding of mechanical components. Fires could also be caused by inappropriate human behaviour, such as construction worker smoking, as well as actions by third party activities and via lightning strikes.

Fires could spread to the forest environment that surrounds the landfall section and cause significant environmental impacts. Chapter 11 Terrestrial Ecology describes the habitats that occur within the Project Area that could be adversely affected by fire. In view of the sensitivity of some of the habitats and their protection status, it is important that stringent measures are enforced to minimise fire risks and the associated potential significant adverse impacts.

Fire risks will be minimised through the definition and enforcement of strict control measures, which will include the adoption of a “permit to work” system for hot works and a smoking ban for all construction personnel whilst undertaking construction activities. Other ignition sources, such as open fires along the pipeline Right of Way (RoW) will also be prohibited, whilst dry vegetation will be removed from the RoW and from areas of hot works.

Section 19.5 indicates that South Stream Transport will prepare an overarching Emergency Preparedness and Response Plan – this plan will include details of fire prevention, fire detection and fire-fighting systems which will be developed and maintained by each construction contractor. Contractors’ Emergency Response Plans will be tailored to work to be carried out under their contracts. These Emergency Response Plans will include specific measures to prevent ignition and subsequent spread of any fires to natural habitats and well as fire-fighting procedures (including interactions with local competent fire-fighting authorities). Contractor Emergency Response Plans will thus make reference to, and be aligned with, South Stream Transport’s overarching Emergency Preparedness and Response Plan.

19.6.1.3 Potential Impacts to Socio-Economic Receptors and Community Health

Damage to Third Party Properties or Utilities

Large mobile construction plant items, such as excavators, dozers and construction vehicles etc. have the potential to cause damage to third party property, whilst the excavation of pipeline trenches could result in damage to buried utilities.

Existing third-party services will be located, marked, and either safeguarded or diverted in accordance with owners agreements, and as further described in Chapter 5 Project Description.
As noted in **Chapter 5 Project Description**, Section 5.3 Construction Phase Description, two existing third-party utility infrastructure installations crossing the landfall section of the Project Area have been identified, namely:

- An existing underground communication cable; and
- A 10 kV overhead power line suspended on poles located approximately 850 m downstream from the landfall facilities.

If utilities such as the communication cable or overhead power line were damaged, in addition to causing damage to the relevant utility operator’s assets, it could also lead to economic impacts on local businesses e.g. potential interruption to communication services and energy supply, as well as potential lost production time. Householders could also experience inconvenience and could potentially make alternative provisions, at personal expense, to cope with a loss of communication services or electricity.

For buried services, at the time of setting out the works, each contractor will locate such services and record depth, type and size through the use of hand excavation. All services will be adequately protected from damage by the laying of excavator mats, or geotextile membrane and hard-core and by maintaining an appropriate safe distance between the pipeline and existing services. Alternatively, in agreement with the service owners (including the underground communication cable), it may be decided to cut and reroute service lines. The final decision will be subject to consultation with the utility owner and detailed design studies.

Due to the height of the overhead power line which is suspended over the access road and construction corridor, it is possible that it may restrict certain types of vehicles from accessing the route. In order to overcome this and to maintain a safe working environment, the power will need to be cut temporarily and either an alternative power system provided or the power lines rerouted so that the construction equipment can travel safely along the route. A decision on which option will be selected will be based on consultation and agreement with the power line owners, local authorities and any other effected parties. South Stream Transport will put in place measures to ensure that disruptions to power supply as a result of accidental damage to services are kept to a minimum.

It is considered that the risks of accidentally damaging either the communication cable or the overhead power line are low taking into account the aforementioned preventative measures.

All reasonable efforts have been made to ensure that all utilities crossing the landfall section of the Project Area have been identified. However, in the event that unknown services are encountered during construction, the potential for damage to that infrastructure will be minimised through the implementation of procedures to stop work in the immediate area until the nature of the services can be established. Project construction activities could restart following the definition of appropriate working methods which would avoid impacting upon the integrity of the subject services and/or the health and safety of the construction personnel. Ownership of the services will be established where possible, and the owners consulted if service diversions are deemed necessary. Additionally, appropriate signage, working practices and worker training will be given should any other overhead cables be encountered.
Chapter 19 Unplanned Events

Fires
As identified in Section 19.6.1.2, fires during the Construction and Pre-Commissioning Phase could occur either as a result of construction activities or as a result of inappropriate human behaviour. Such fires have the ability to impact upon local community assets and the health of local community residents.

Chapter 14 Socio-Economic describes the land uses that occur within the Project Area and within adjacent areas that could be adversely affected by a fire. Sections of the Project Area are forested, interspersed with pockets of open land used primarily for agriculture (including vineyards). The agricultural land is a mixture of shrubby and fallow land and productive agricultural land, mainly vineyards. While fires could spread to neighbouring vineyards and other agricultural land, causing the loss of established productive vineyards, it would be easier to fight and contain a fire spreading through agricultural land compared to forests. Consequently, the potential for economic losses would be limited.

The amount of residential accommodation within the vicinity of the Project Area (as defined in Chapter 1 Introduction) is limited. There are no residential properties, either permanently occupied or holiday accommodation, within the Project Area. However, there are the Shingari and Don holiday complexes (tourist resorts) (approximately 1.3 km south of the microtunnel entry points), a group of residential dwellings situated approximately 1.5 km south of the landfall facilities, as well as more concentrated residential developments in Gai Kodzor (approximately 4.5 km northeast of the landfall facilities), Sukko (approximately 3 km south of the microtunnel entry points), Supsekh (approximately 4 km north of the nearest point of the pipelines) and Varvarovka (approximately 1.5 km northwest of the landfall facilities) plus two log cabins that have been built approximately 1.1 km south of the landfall facilities (see Chapter 9 Air Quality – Section 9.6.1.5). The nearest identified buildings are thus located near the Varvarovka community approximately 1 km northwest of the landfall section with the intervening land being agricultural in nature with some woodland. The risk from fire to the Varvarovka community is minimal given the distance to Project activities and given the sparse nature of the vegetation between the Project Area and that settlement. Nevertheless, the enforcement of strict fire control measures and the fire detection and fire fighting enactments of the Contractors’ Emergency Response Plan (see Section 19.6.1.2) will limit the potential for fire impacts upon residential property.

Protests and Communal Violence
Local residents in the vicinity of the Project Area could potentially be impacted by unplanned events involving construction workforce unrest, civil unrest and worker-community conflict.

Measures will be undertaken to prevent unplanned events caused by the construction workforce protests and disturbances. The construction contractors have the responsibility to provide for the well-being of their workers – this includes compliance with applicable employment laws and regulations, adherence to appropriate OH&S management systems, and the availability of a worker consultation and grievance process. Grievances raised by workers, including South Stream Transport employees and contractors / suppliers’ workers, will be handled according to the Worker Grievance Procedure. This procedure is part of the HSSE-IMS and will be implemented via the Environmental and Social Management Plan (ESMP) (see Chapter 22...
Environmental and Social Management). It will function through all Project phases. The Worker Grievance Procedure will be implemented by South Stream Transport in partnership with its contractors and will ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way.

In addition, the well-being of workers will also be assisted through the adoption of the policies and practices including the following (see Chapter 14 Socio-Economics):

- Human health resources;
- Working relationships;
- Working conditions and terms of employment;
- Workers’ organisations; and
- Non-discrimination and equal opportunities.

In order to minimise the risks associated with workforce conflicts and civil unrest caused by Project activities, South Stream Transport will ensure that the construction contractors adhere to considerate construction practices, including the measures detailed in this ESIA. South Stream Transport will also ensure that security personnel adhere to internationally recognized human rights principles in the provision of Project security services.

As detailed in Section 19.5, South Stream Transport will develop a Security Plan that sits within the broader HSSE-IMS (see Chapter 22 Environmental and Social Management) and is integrated with the other South Stream emergency plans discussed in this chapter. Contractors are required to align their own security plans and procedures with the requirements specified in the South Stream Transport Security Plan and in doing so demonstrate due consideration of both applicable law and the Voluntary Principles on Security and Human Rights (the ‘Voluntary Principles’). Further detail concerning the Project’s implementation of the Voluntary Principles is provided in Chapter 14 Socio-Economics.

To further mitigate against civil unrest, South Stream Transport will prepare and implement the Stakeholder Engagement Plan. The Stakeholder Engagement Plan will define community engagement activities that will be undertaken and adhered to, including ensuring access to a suitable community grievance procedure, and undertaking an appropriate community engagement and awareness programme.

In the event of construction workforce / community unrest or conflict there could be human injuries. Therefore, the Emergency Response Plans that will be prepared and maintained by each construction contractor will include measures that aim to protect the workforce and members of the public. These plans will define measures that aim to initially stabilize medical cases (which would be carried out by an on-site first aider, nurse or physician) and then enable evacuation carried out by ambulance or helicopter. The injured party would be evacuated to the nearest designated hospital or accident and emergency centre. Each contractor will ensure that sufficient first-aid or medical staff and equipment are located at the construction site to meet the identified occupational health risks. The location and capability of local ambulance stations (public and private) will be identified (and mapped) together with contact details, times of operation, distance and travel times. A qualified occupational physician will inspect and report on the capacity and capability of these services. A designated hospital or accident and
emergency centre will also be identified (including contact details, times of operation, distance and expected travel times).

**Traffic Accidents**

Pipe sections and other materials will be delivered to the landfall section of the Project from the Novorossiysk port by road using designated access routes. Stakeholder engagement consultation has identified public and community safety concerns as related to traffic accidents when construction vehicles pass through residential settlements *(Chapter 6 Stakeholder Engagement)*. Such traffic accidents could be caused by equipment malfunction or by human error.

South Stream Transport will ensure a range of measures will be implemented prior to construction works to address transportation related risks and impacts, including:

- Preparation and implementation of a Logistics Plan to manage and coordinate the transport and logistics requirements of the Project. The Logistics Plan will identify agreed access routes, as well as measures and safeguards to minimise interference with local transportation and routes;

- Preparation and implementation by the contractor of a Construction Traffic Management Plan (CTMP). The CTMP will:
  - Be consistent with, and take into consideration, the Construction Traffic Management Plan (or equivalent) developed for the Russkaya Compressor Station Project;
  - Be aligned with the Logistics Plan and ensure that access to the pipeline landfall and associated above ground installations will be restricted to the agreed access routes and the construction corridor;
  - Ensure that movement of ‘outsize’ or ‘large / long’ vehicles, or convoys, will be timed, where practicable, to avoid busy traffic periods and routed to avoid minor roads and villages; and
  - Include strict enforcement of speed limits for employees driving company vehicles and adherence to driving and health and safety guidelines during both work and non-work hours.

- The implementation of safe driving procedure protocols. These protocols will include the following measures:
  - Drivers will be briefed to maintain vehicular access to all existing properties and relevant safety measures to be applied along the designated construction access routes;
  - Training and enforcement to ensure that all South Stream Transport / contractor drivers adhere to all applicable national legislative requirements and driving conditions as specified by South Stream Transport;
  - All drivers will be trained in ‘well driven’ principles and guidance (Ref. 19.7); and
  - Driving performance will be assessed and monitored with additional training provided if necessary.

Contractors will also be required to regularly inspect and maintain their construction fleet in order to minimise accident risks as associated with mechanical failures. In addition to these risk reduction measures, contractor’s Emergency Response Plans will include specific measures to be
undertaken in the event of vehicle accidents, including those involving third parties. Any traffic induced oil spillages will be handled in accordance with the contractors Spill Prevention and Response Plan (Section 19.6.1.2).

19.6.2 Commissioning and Operational Phase – Landfall Section

19.6.2.1 Events Identification

During the Operational (including Commissioning) Phase of the Project, unplanned events in the onshore landfall section may occur as a result of accidental leakages of natural gas from the pipeline or from landfall facilities which have the potential to result in fires and explosions.

Table 19.2 lists the activities that could result in an unplanned event, a description of the unplanned event, and the receptors which could be affected.

Some unplanned events have been excluded from the assessment undertaken in this section as they are not expected to lead to significant environmental or socio-economic impacts. Unplanned events that have been excluded from discussion are:

- **Spills of liquid hydrocarbon**: these events could occur during maintenance operations at the onshore landfall facilities, but the frequency of such operations and the volumes of hydrocarbon involved are sufficiently small enough not to warrant a detailed discussion of these events. Such events can be readily accommodated through applicable Emergency Response Plan and Spill Prevention and Response Plan;

- **Vehicular traffic accidents**: considering that no significant vehicular traffic will be associated with the Operational (including Commissioning) Phase of the Project, this aspect has been excluded from the assessment; and

- **Operational worker protests and / or disturbances**: As there will be no full time workers employed for the Project during the Operational Phase of the Project, issues associated with potential worker protests and / or disturbances are thus excluded from the assessment.
19.6.2.2 Potential Impacts to Environmental Receptors

Gas Leakages

The only possible source of a large scale release of gas into the atmosphere would be the result of a pipeline rupture or a planned release of gas from the landfall facilities or pipelines to allow maintenance or repairs to take place. Pipeline ruptures could be caused by factors such as external interference, internal or external corrosion, material and construction defects or ground movement / geohazards. Statistically, a pipeline rupture is a very rare event and the likelihood of such an extreme situation is very low (refer to failure frequencies as detailed in Table 19.3). Table 19.4 also provides calculated failure frequencies for the landfall facilities.

</tbody>
</table>

The Project pipelines and the landfall facilities will be designed in compliance with national and internationally recognised standards (Section 5.2.6.1). The Project has developed specific design criteria taking into account Russian legislation and international pipeline industry standards, notably those of Det Norske Veritas¹, and European Standards that apply to the Project overall that aim to minimise the risk associated with gas leakages (and subsequent fires / explosions) and thus protect the environment, the operational workforce, as well as members of the public in surrounding areas. Of note is that the Project design takes account of potential terrestrial geohazards as described in Appendix 19.3.

Such measures aim to minimise the risks of pipeline failures which could result in large scale gas releases. Consistent with GIIP, the landfall facilities in Russia will have local Emergency Shutdown (ESD) valves and safety systems (e.g. alarms and trip systems) installed for each pipeline (Section 5.2.5.2). An ESD valve is a hydraulic actuated and spring return valve designed to stop the flow of a hazardous substance (i.e. the gas) upon the detection of a potentially dangerous unplanned event or non-standard operating conditions. In the unlikely event of rupture of one of the Project pipelines the ESD system will be triggered and the pipelines will isolate themselves. The gas volume in the pipelines will then be automatically isolated from the

¹ As per Section 5.2.6.1, the Project Specific Design Code (PSDC) will be developed during the detailed design stage and which will be primarily based on Det Norske Veritas (DNV) Offshore Standard DNV OS-F101 code ‘Submarine Pipeline Systems, 2010’ (DNV-OS-F101, 2010). DNV will certify that the offshore gas pipeline is compliant with DNV-OS-F101.
landfall facilities, by closing the landfall facilities inlet and outlet ESD valves, thereby stopping the flow of gas to the pipelines.

The landfall facilities will be equipped with a vent stack. The venting system is designed for venting the gaseous inventory of the pipework within the landfall facilities to the atmosphere (to depressurise) in cases of planned shutdown or maintenance of the pipelines. During normal operations, the vent stack will not emit any gas. Venting will only take place during planned maintenance or shutdown activities that may require gas within certain areas of the landfall facilities to be released to atmosphere (Section 5.6.2.1).

For safety purposes, the location of the vent stack structure is chosen such that the prevailing wind blows gas away from the landfall facilities. The vent stack height has been pre-determined based on safety requirements in the workplace in order to protect workers at the facility from asphyxiation, to ensure adequate dispersion in the atmosphere, and to ensure that an explosive mixture is not present at ground level.

**Fires**

If leaked gas is ignited, significant acute environmental impacts could be caused by the resulting fire, potentially at large distances from the Pipeline itself in the case of a full bore rupture event (especially if there are dry conditions at the time of such a fire event). In many instances, the area would recover relatively quickly from the effects of a fire (e.g. areas of grassland). However, if the fire was within or adjacent to a woodland area, there may be longer-term environmental damage.

Consistent with GIIP, the likelihood of occurrence of fires will be minimised through the use of a Fire & Gas (F&G) detection system that aims to protect and alert personnel and assets from the consequences of a fire and / or gas release. The F&G detection system is a safeguarding system which acts completely autonomously from other safety systems (Section 5.2.5.7). The landfall facilities F&G detection system will include a number of strategically placed gas, flame and smoke detectors. In addition, the containers housing the electrical and instrumentation (E&I) equipment will be fitted with gas, flame and smoke detection systems as appropriate. The main piping will also be installed underground as much as possible, whilst ESD valves will be installed in pits to minimise exposure to fire and explosion events. Such measures will further reduce the potential occurrence and magnitude of fire events.

In an emergency the landfall facilities will be isolated from the offshore pipeline and the Russkaya CS in Russia and the Receiving Terminal in Bulgaria. There is no requirement for emergency venting (i.e. venting is not part of the ESD logic). However, provisions exist to enable a manual depressurisation of the landfall facilities, if required.

In case of a gas-fuelled fire at the landfall facilities, rapid isolation of the leak will be undertaken as quickly as possible which will reduce the magnitude of any gas leak and limit the duration and intensity of possible fires. The rapid initiation of the isolation provisions will occur following detection of a gas leak or fire by the installed alarm systems. The quantity of gas within the landfall facilities (between the inlet and outlet valves) depends on the operating conditions at the time the valves are closed. The maximum quantity of gas that could be present within the landfall facilities is 42,830 kg.
Additional measures will include the development of an Emergency Response Plan, inclusive of fire prevention and suppression measures (see Section 19.6.1.2). The fire prevention and response measures will include specific actions to prevent the spread of any fires to the surrounding environment. However, provisions for active fire fighting are not foreseen for fire protection of the equipment within the landfall facilities as water based extinguishing systems are not considered an effective measure to extinguish or mitigate the effects of gas fires on gas containing equipment.

19.6.2.3 Socio-Economic Receptors and Community Health

Gas Leaks and Fires

Gas leakages have the potential to impact upon human health receptors. Short term exposure to low concentrations of natural gas may cause headaches, dizziness, drowsiness, nausea and vomiting. High gas vapour concentrations may lead to unconsciousness due to the absence of oxygen. Natural gas is extremely flammable, forming a flammable mixture at a concentration of approximately 5% gas in air (by volume). Therefore, in the unlikely event of a gas leakage, the main risk of concern to community facilities and health is associated with fire and explosion rather than gas exposure.

As identified in Section 19.6.1.3, in the event of a fire, it could spread to the environment that surrounds the landfall section, although fires are unlikely to reach private and residential properties located in the Shingari and Don holiday complexes and Gai Kodzor, Sukko, Supsekh and Varvarovka residential areas.

Section 19.6.2.2 indicates that the Project Pipeline has been designed in a manner that aims to minimise the risks associated with gas leakages and subsequent fires or explosions and thus risks posed to members of the public in surrounding areas. Notwithstanding the stringent standards of design and construction that have been adopted by the Project, it is acknowledged there is a small residual risk that leakages of gas could occur from the pipeline and landfall facilities which could result in a fire / explosion. In developing the Project design, potential third party interference has been taken into account such that the pipeline design includes measures to reduce accidental damage, whilst the landfall facilities will be secured by security fencing, intruder alarms and the surveillance of the real time Closed-Circuit Television (CCTV) by staff based in the Central Control Room (CCR) in accordance with a Security Plan that is being developed by South Stream Transport for the Project.

As indicated in Section 19.6.2.2 during operation, a vent stack located just outside the landfall facilities will be used to depressurise the landfall facilities during a planned shutdown. Given that the vent stack has been designed in order to provide for the safe venting of gas, it is not expected that this venting would pose a risk to the health of residents at nearby receptors given their distance from the vent stack (a minimum 1.1 km). Due to the presence of hydrogen sulphide and mercaptans in the gas, perceptible odour impacts may be expected to occur on a short-term infrequent basis during venting, but this would not be expected to represent a risk to health.

Whilst the risks of a pipeline gas leakages are inherently very low, it is essential to determine what the consequences of any gas leakage could be (ignition and explosion, for example) upon
surrounding receptors, and assess the measures that can be implemented to reduce the effects of any such event, regardless of how small the likelihood of occurrence. Such information can then be used to define exclusion zones around Project facilities, within which activities and land uses are restricted. Definition of exclusion zones for the Project has been assisted through the completion of a Quantitative Risk Assessment (QRA) study that has analysed all components of the landfall section of the Project and, based on historical data on components failure and accidents' occurrence, determine the probability of possible leakages, quantify the leakages and determine the associated potential impacts on the public (Ref. 19.1) (Appendix 19.1).

The QRA undertaken has considered the risks to the public associated with the operation of the landfall sections by taking into account the hazards due to the release and dispersion of:

- Toxic substances either contained in the hydrocarbon gasses or used in the processing of these substances, if present; and
- Gaseous and liquid hydrocarbons as well as subsequent fires and explosions.

The QRA was performed following a pipeline specific approach with pipeline specific data. This approach was also applied for the landfall facilities. The risks have been calculated and expressed in terms of Individual Risk (IR) and Societal or Group Risk (GR). As detailed in Appendix 19.1, the QRA considered the risks to the offsite population expressed as the fatality risk per year.

The QRA study has assessed whether the risk to people resulting from the onshore pipeline section (and the landfall facilities) falls within the risk acceptance criteria of the international pipeline industry standards adopted by the Project, and it has enabled a clear and consistent set of exclusion zones to be defined for the Project. Details of the QRA methodology, acceptance criteria and scenarios tested are presented in Appendix 19.1.

The QRA shows that the highest IR is at the ground surface directly over the buried pipeline (maximum $1.8 \times 10^{-7}$ per year) – this is below the acceptance criteria of $1 \times 10^{-5}$ and $1 \times 10^{-6}$ per year.

The population density in the surrounding areas of the planned pipeline route is such that the group risk criteria is not exceeded. No residential buildings are located in the range of the maximum effect distance of 680 m to 690 m (i.e. the maximum distance away from an event that would be adversely affected).

The QRA also shows that for the landfall facilities the distance from the facility fencing to the 1 x $10^{-5}$ per year, 1 x $10^{-6}$ per year and 1 x $10^{-7}$ fatality risk per year contours occur at distances of approximately 20 m, 150 m and 370 m respectively.

Table 19.5 presents the proposed exclusion zones that have been defined for the landfall section of the Project for the protection of public health and infrastructure. These are in accordance with the requirements of Gazprom Standard STO 2-2.1-249 – 2008 for Main Gas Pipelines, the regulatory requirements set out for the Proekt (the Russian Project Design Documentation), and informed by the results of the QRA (Ref. 19.1).

The defined exclusion zones are sufficient to meet the risk acceptance criteria on individual and societal risk for the Project, as defined by industry standards, and to meet the requirements on exclusion zones from local Russian legislation and regulations.

**Protests and Communal Violence**

Local residents in the vicinity of the Project Area could potentially be impacted by unplanned events involving local civil unrest as associated with Project activities. Such events may occur because of misperceptions or lack of knowledge about the Project.

In order to minimise the likelihood of any civil unrest triggered by the Project’s activities, South Stream Transport will prepare and implement the Stakeholder Engagement Plan which will define community engagement activities to be undertaken and adhered to, including public access to a suitable community grievance procedure, and a community consultation and awareness programme. During the Operational (including Commissioning) Phase it will be important to manage the community perception of gas leakage (and fire) risks through the provision of clear information about the Project and its risks during the community consultation and awareness programme.

**19.6.3 Decommissioning**

The decommissioning programme will be developed during the Operational Phase of the Project (expected service lifetime of the South Stream Offshore Pipeline is 50 years). It is likely that the technological options and preferred methods for decommissioning of such gas transportation systems as the South Stream Offshore Pipeline will be different in 50 years’ time.

Consequently, unplanned events associated with the Decommissioning Phase are unknown at this stage; however, it is anticipated that some of the potential unplanned events will be similar in nature to some of those that may arise during the Construction and Pre-Commissioning
Chapter 19 Unplanned Events

Phase. As such, the mitigation actions as defined in Sections 19.5.1 are also likely to be applicable to the Decommissioning Phase.

Under all circumstances, decommissioning activities will be undertaken in accordance with GIIP and with the applicable international and national legislation and regulations prevailing at that time, and in liaison with the relevant regulatory authorities. As part of the decommissioning planning programme, the potential for unplanned events will be considered and appropriate mitigation and management measures put in place to reduce risks and consequences to the surrounding environmental and local community receptors.

19.7 Nearshore and Offshore Section

19.7.1 Construction and Pre-Commissioning Phase – Marine Section

19.7.1.1 Events Identification

During the Construction and Pre-Commissioning Phase of the Project, unplanned events in the nearshore and offshore sections may occur as a result of offshore construction activities, use of maritime vessels and as a result of maritime vessel accidents.

Table 19.6 lists the main activities that could result in an unplanned event, a description of the unplanned event, and the receptors which could be affected.

**Table 19.6 Marine Activities Potentially Resulting in an Unplanned Event (Construction and Pre-Commissioning Phase)**

<td>Maritime accidents or collisions leading to oil spills (including during bunkering)</td>
<td>✔</td>
</tr>
</tbody>
</table>

Table 19.6 indicates that during the Construction and Pre-Commissioning Phase, there is a risk of maritime vessel accidents and collisions. These events have the potential to impact upon socio-economic and human health receptors. Such maritime vessel accidents and collisions can also result in oil spillages which can have resultant impacts upon environmental, as well as socio-economic receptors. Table 19.6 also indicates the risks associated with the introduction of invasive species by maritime vessels.
In order to assist in defining the risks and potential knock-on environmental impacts associated with maritime accidents and associated oil spills, a maritime risk assessment has been undertaken which has included modelling of marine oil spills that are considered most likely to occur (due to accidental collisions / grounding of marine vessels or during vessel bunkering (refuelling) at both nearshore and offshore locations). The risk assessment assists in defining risk management activities. Details of the maritime risk assessment are presented in Appendix 19.2 which highlights the potential likelihood of accidents occurring. Appendix 19.2 also presents results from the oil spill modelling which has been used to assess the implications and risk management activities as related to environmental, socio-economic and human health receptors as detailed below.

Some unplanned events have been excluded from the assessment as they are not expected to lead to significant environmental or socio-economic impacts. Unplanned events that have been excluded from discussion are:

- **Spillages and discharge of potentially hazardous materials other than fuel / oil spillage**: Spillage of relatively small quantities of potentially hazardous chemicals (discharges of grey / black waste, sewage, garbage, bilge and oily water) from marine plant / vessels can be readily managed through ensuring that vessels operate in accordance with the Marine Pollution (MARPOL) Convention, the Black Sea Contingency Plan and national regulations. All contractors and operators of vessels working on behalf of South Stream Transport will be required to prepare Shipboard Marine Pollution Emergency Plans (SMPEP) as applicable for each vessel. Effective implementation of the SMPEP will mean that the implications of any such events will be sufficiently small enough not to warrant a detailed discussion of these events herein;

- **UXO Clearance**: Pipelay will be preceded by an unexploded ordnance (UXO) survey on part of the route, which will establish the need, and provide guidance for, the removal of boulders, rocks or potential UXO. A UXO clearance plan (if required) will take into consideration the presence of sensitive cultural heritage, marine biological and physical receptors, and will aim to avoid or reduce adverse impacts on these receptors. This process will be managed through the management of change process described in Chapter 5 Project Description. The UXO Clearance Plan (if required) will be developed by the Contractor subject to review and acceptance by South Stream Transport in close conjunction with the relevant authorities at the appropriate time. In the event that UXO requires clearance (controlled detonation) in close proximity to an as yet unidentified Cultural Heritage Object (CHO), the possibility that the CHO might be damaged or lost cannot be discounted. Chapter 16 Cultural Heritage discusses this issue further noting that the likelihood of such an event is considered remote. UXO clearance via a controlled detonation also has the potential to result in behavioural disturbances to fish / mammals over several kilometres; and

- **Impacts of unplanned pipeline construction events**: During the Construction and Pre-Commissioning Phase a range of unplanned construction events may be encountered, including wet buckle events (whereby the submerged pipeline buckles under pressure and floods with water) or failed hydrotest. Such events have the potential to result in significant construction delays and associated costs. It is considered that the environmental implications of such events (such as pipeline recovery, disposal, relaying) would be similar
to the environmental impacts as associated with routine construction activities as reported within this ESIA. Under such circumstances, remedial activities will be undertaken in accordance with GIIP which will limit the potential for significant environmental impacts.

19.7.1.2 Potential Impacts to Environmental Receptors

Invasive Species

Vessel operations have the potential to inadvertently introduce invasive alien species, either in ballast water, on the biofilm inside ballast tanks or carried as fouling organisms on the vessel hulls. Historically, some introductions of alien species have had extreme ecological consequences, either directly through the introduction of benthic predators such as *Rapana venosa* or through system wide perturbations as exemplified by the invasion of the planktonic ctenophore *Mnemiopsis leidyi*. In other instances, such as the introduction of the bivalve *Anadara inaequivalvis*, the effects have been less severe and in the case of *Beroe ovata*, have in fact served to redress some of the ecological perturbations caused by *M.leidyi*. See Chapter 12 Marine Ecology for more information.

Despite its low likelihood of occurrence, there is the possibility of population or community-wide effects on the entire ecology of the Black Sea should invasive alien species be inadvertently introduced. Introduced invasive planktonic species can out-compete native plankton species and cause changes to the marine food web. As such, introduction of invasive species can lead to the decrease in populations of pelagic fish that are the main food of most cetaceans or seabirds. Introduction of benthic predators such as *Rapana venosa* can cause changes to benthic species diversity which in turn can impact larger species (fish, birds or mammals) which feed on these species.

Given the above, the introduction of invasive species, although a rare event, could potentially have significant adverse environmental consequences. It is therefore a key objective of the Project to minimise the likelihood of occurrence of the introduction of invasive species and to develop measures that would effectively minimise the adverse impacts on potentially impacted marine habitats and associated species. Mitigation measures to be applied include the following:

- Where relevant and practical the IPIECA (Global Oil and Gas Industry Association for Environmental and Social Issues) document Alien Invasive Species (Ref. 19.13) and the Oil and Gas Industry, Guidance for Prevention and Management and the International Maritime Organisation (IMO) Ballast Water Management Convention and Guidelines. They will be applied to all marine plant and equipment that is used on the Project and which has the potential to be a vector of live organisms, spores, larvae and young and will include ballast water management, use of antifouling coatings, cleaning of equipment prior to deployment and the change of cooling water. The Contractor HSSE Plan will contain a detailed description of the actions to be taken to implement these requirements, where possible and practicable, including:
  - Vessels entering the Black Sea will have on-board, and implement, a Ballast Water and Sediment Management Plan;
Vessels entering the Black Sea will have a Ballast Water Record Book to record when ballast water is taken on board; circulated or treated for ballast water management purposes; and discharged into the sea or reception facilities;

Vessels entering the Black Sea using ballast water exchange will conduct ballast water exchange as far from the nearest land as possible, and in all cases at least 50 nautical miles (nm) from the nearest land and in water at least 200 m in depth;

Vessels entering the Black Sea will conduct ballast water management in accordance with their year of construction and ballast water capacity and with either the ballast water exchange standards or ballast water performance standards;

Careful cleaning of hulls and tanks before use and prior to entering the Black Sea; and

Use of anti-fouling coatings (non-TBT) or sealing coatings to minimise inadvertent transport of organisms.

Maritime Vessel Collisions and Oil Spillages

A maritime vessel collision could conceivably occur at any location along the offshore section of the pipeline route, although the likelihood of such a collision occurring is considered to be very low. The likelihood that such an incident would result in an oil spill is even lower, as a high-energy collision would be required to damage a vessel to such an extent that marine diesel was spilled into the sea.

Appendix 19.1 presents details of maritime risk assessment which has entailed the following:

- Estimate the likelihood of an oil spill occurring following a maritime collision (based on available historical information), and rank these into categories;
- Estimate the severity of the potential consequences of any oil spill that could occur and rank these severities into categories;
- Construct a risk matrix of likelihood and consequence severity; and
- Assess various oil spill scenarios and determine their overall risk rating.

Following an evaluation of potential unplanned collision events, the oil spill scenarios (involving marine diesel oil - MDO) as detailed in Table 19.7 were defined, together with details of potential resultant oil spillages. The maritime risk assessment (Appendix 19.1) goes on to indicate that such unplanned collision events do not present a major risk of oil spills and that overall risk ratings are considered to be acceptable.

On the basis of the scenarios above, oil spill modelling has been undertaken for selected highest risk scenarios (details are included in Appendix 19.2) and include a nearshore spillage of 1,200 m³ of MDO and an offshore spillage of 2,000 m³ of MDO. Figure 19.2 illustrates the oil spillage locations that have been modelled.

Oil Spillage Risk Factors

The severity of the consequences of an oil spill depends on several factors including (a) type of oil spilled, (b) the amount of oil spilled and, perhaps most importantly, (c) the proximity of the oil spill to oil-sensitive resources. These issues are considered in the sections below.

a) Type of Oil Spilled

Maritime vessels typically use the following types of fuel oil:

- Marine gas oil (MGO): consisting of only distillates from oil-refining. This fuel is used in the small diesel engines of boats and smaller ships and can be used in auxiliary equipment such as generators and compressors;
- Marine diesel oil (MDO): A blend of heavy gas oil that may contain small amounts of black refinery feed stocks. This is used as fuel by the medium-speed diesel engines of smaller ships and can also be used in auxiliary equipment such as generators and compressors; and
- Intermediate Fuel Oils (IFO): Blends in varying proportion of gas oil and residues from crude oil distillation. This includes IFO-380 or Heavy Fuel Oil (HFO) consisting almost entirely of residues. HFO is used to power the slow-speed cross-head diesel engines used in most large ships and requires heating and purification when stored and used.

Oils have been classified by the International Oil Pollution Compensation Funds, the body involved with compensation for oil spills from tankers, into two groups; 'persistent' oils and 'non-persistent' oils:

- Persistent oils include most crude oils and HFO. When spilled on the open sea these oils progressively ‘weather’ to produce high-viscosity, water-in-oil emulsions that are very persistent on the sea surface and which contaminate shorelines when they drift ashore; and
- Non-persistent oils are mainly distillate fuels such as gasoline and diesel fuel. When spilled in the open sea these oils evaporate to some degree and are rapidly dispersed and dissipated by the prevailing wave action. MGO and MDO are classified as being non-persistent.

Taking into account the above, where practical, Project vessels deployed in the Project Area will use MGO or MDO, commonly referred to as ‘marine diesel’ and conforming to ISO-8217:2010 Marine Distillate Fuel Grades DMA, DMB or DMZ (rather than persistent oils such as most crude oils and Heavy Fuel Oil (HFO). As such, the oil spill modelling undertaken as detailed in Appendix 19.1 only considers oil spill scenarios that involve marine diesel.

b) Amount of Oil Spilled

The amount of oil spilled from an incident influences the area which is potentially affected. A large volume oil spillage has the ability to impact a wider area than a lower volume spillage given the ability of wind, waves and marine currents to disperse oil spillages.

c) Proximity of the Oil Spill to Oil-Sensitive Resources
Oil spills in the open ocean appear to be dispersed and dissipated by the effects of wind, waves and currents which reduces their ability to reach coastal sites. Some scattered tar balls can be found along coastlines which are evidence of past oil spills of crude oil and HFO, or caused by operational activities such as tank-washing.

**Potential Impacts Upon Marine Ecology Sensitive Receptors**

Typically ecological impacts are more severe when oil spills occur in shallower nearshore waters where spilled oil can affect the shoreline or be naturally dispersed into shallow water by wave action. Different organisms have different sensitivities and vulnerabilities to the toxic and physical effects of spilled oils. A spill of a relatively small amount of oil close to particularly sensitive coastal sites such as mud-flats and salt marshes can cause more ecological damage than a larger oil spill further from such sensitive sites. Spilled oil that becomes naturally dispersed by wave action in shallow water can cause adverse effects to habitats such as fish nurseries.

The principal areas of ecological concern with respect to oil spills are:

- Impacts on organisms in the water column; such as marine mammals, plankton and fish in open water, caused by the potentially toxic components in oils;
- Impacts on seabirds on the sea surface caused by oil contaminating the plumage of seabirds leading to the loss of insulation and subsequent hypothermia; and
- Impacts on coastal habitats (including bird populations) should the spilled oil at sea subsequently drift ashore where damage may be caused by the physical nature of the emulsified oil that smothers small organisms.

Section 12.4 of this ESIA Report (Baseline Marine Ecology) describes the marine habitats within and in proximity of the Project Area. This section indicates that along the eastern Black Sea coast, faunal groups of particular interest, either due to their value or vulnerability, include a variety of commercial fish species (e.g. anchovy, turbot, sprat etc.), endangered species (e.g. sturgeon), marine mammals and seabirds. Marine flora is also important, particularly red and brown macroalgae.

**Oil Spill Mitigation Measures**

Given the presence of the sensitive marine ecological species as indicated in the section above, an oil spill would potentially have significant adverse consequences. It is therefore a key objective of the Project to minimise the likelihood of occurrence of an oil spill and to develop Oil Spill Prevention and Response Plans that would effectively minimise the potential for adverse impacts on potentially impacted marine species and habitats.

Mitigation measures to be applied include the following:

- Where practical, vessels deployed in the Project Area will use MGO or MDO and, therefore, any accidental spill of fuel will have less adverse consequences than a spill that involves heavier fuels;
- All contractors and operators of vessels working on behalf of South Stream Transport will be required to develop and implement an Oil Spill Prevention and Response Plan. South Stream...
Transport will ensure that contractor Oil Spill Prevention and Response Plans are appropriately aligned with the Black Sea Contingency Plan (Ref. 19.2). The Oil Spill Prevention and Response Plans will specifically target the prevention of potential oil spillage incidents as detailed in Table 19.7;

- The contractor will develop and implement Standard Operational Procedures (SOPs) which will define procedures that involve the handling of fuels / oils that aim to minimise the potential for spillages;
- Contractors and operators of vessels working on behalf of South Stream Transport will operate in compliance with MARPOL regulations on oil spill prevention and response and are required to prepare Shipboard Oil Pollution Emergency Plans (SOPEP) and Shipboard Marine Pollution Emergency Plans (SMPEP) as applicable for each vessel (Ref. 19.3; Ref. 19.5). The SOPEPs will specify the control and response measures that have to be available on board every vessel to respond to a spill that does not require external intervention; and
- Marine vessel crews will have the appropriate training, qualification and certification to undertake the tasks required during the construction of the pipelines.

The mitigation measures indicated above will minimise the likelihood of an oil spill occurring, and thus reduce the potential adverse impacts to marine habitats in the event of a spill.

19.7.1.3 Potential Impacts to Socio-Economic Receptors and Community Health

Invasive Species

As detailed in Section 19.7.1.2, vessel operations have the potential to inadvertently introduce invasive alien species, either in ballast water, on the biofilm inside ballast tanks or carried as fouling organisms on the vessel hulls. As the introduction of invasive species can have knock-on effects for larger species higher up the food chain; commercially important fish populations could be impacted through a decrease in the availability of their food source. A collapse or reduction in the fish stocks would cause a reduction in the fish available to local fishers.

The mitigation measures as detailed in Section 19.7.1.2 aim to minimise the likelihood of occurrence of the introduction of invasive species which thus minimise the potential for adverse socio-economic impacts as related to fish stock levels.

Maritime Vessel Collisions and Oil Spillages

Beach Users and Tourism

The mitigation measures as highlighted in Section 19.7.1.2 minimise the risk of an oil spill occurring. In addition, the maritime risk assessment and oil spill modelling results as included in Appendix 19.2 has established that the construction of the sub-sea natural gas pipelines across Russian waters does not present a major risk of oil spills and that the fuels used by Project vessels, if spill, would evaporate to a significant degree with the remainder being naturally dispersed in the water column by wave action within a few days of being spilled.
Nevertheless an oil spill could, in theory, give rise to adverse impacts on the tourism industry in the Anapa Region. Chapter 14 Socio-Economics, Section 14.4.10 Baseline has identified that the Anapa Region is a focal point for coastal-related tourism and that the industry is a major employer in the region. The baseline has also identified that the tourism industry in the Anapa Region, particularly that which is focused on beaches and coastal activities, is heavily concentrated to the south of the Project Area (e.g. Sukko Beach).

An oil spill could potentially spread beyond the immediate area and could reach the coastal areas to the south of the Project Area, thereby potentially impacting the key coastal tourism precinct in the Anapa Region. If there was an oil spill that prevented tourists from using the beaches, swimming in the sea, or pursuing other Black Sea based or related recreational activities, the tourism industry in the Region could suffer economically (including long term tourist cancellations). However, as for beach users themselves, the severity of the impact would depend on the extent of the spill, its distribution and whether or not it occurred just prior to or during the peak summer season. Considering that any disruption due to oil spillages would be limited to a few days indicates that the economic impact on the tourism industry would be limited, even if the spill did occur just prior to or during the peak summer season.

Potentially, the greatest risk associated with an oil spillage would be to the reputation of the Region’s beaches, and associated tourism industry, as an attractive and pristine seaside holiday destination. This could lead to a drop off in bookings over the remainder of the season and, possibly even in subsequent years. The relatively short duration of any visible oil in the water would limit the opportunity for adverse publicity, especially of a visual nature. However, the possibility of reputation damage for the area cannot be discounted. As described in Section 19.7.1.2, Project marine construction activities do not present a major risk of oil spills whilst construction-related activities in the marine environment that could give rise to an accidental oil spill will be undertaken in line with the Oil Spill Prevention and Response Plans to be prepared by contractors and operators of vessels working on behalf of South Stream Transport. Such measures thus minimise the risks of an oil spill and subsequent adverse impacts upon beach users and tourism.

**Fisheries**

Oil spills have the potential to affect fishery resources in a number of ways as described in the sections below.

*Fish or Other Seafood Products - Mortality*

Despite the susceptibility of juvenile stages of fish to relatively low concentrations of oil in the water column, adult free swimming fish and wild stocks of commercially important species will tend to swim away after detecting oil in the water column and thus it is unlikely that a spill will cause serious mortalities in any wild stocks. In general, juvenile fish and eggs are significantly more susceptible to oil pollutants than adults, and thus oil spillages can result in localised mortalities. Following a spillage, the reproductive success of unaffected fish, as well as the influx of eggs, juveniles and adults from unaffected areas leads the recovery of stock numbers. Given that many marine species produce vast numbers of eggs and larvae that are widely distributed by tidal currents means that species can recover from any mortality events as a result of short-term unfavourable conditions. Thus, the depletion of adult stocks is very rarely...
recorded following spillages as marine organisms can generally adapt to high mortalities though production of large numbers of eggs and replacement from outside the affected area.

Oil concentrations in the water column decline rapidly and are normally confined within the area of the spill so the impacts will be potentially more significant nearshore on more sessile animals, such as mussels. As well as mortality, there may be other effects such as changes in behaviour, feeding, growth or reproduction.

The impacts of an oil spill will depend upon the type of oil used - Section 19.7.1.1 details that spillages of non-persistent oils such as MGO and MDO when spilled in the open sea evaporate to some degree and are rapidly dispersed and dissipated by wave action. The effects of an oil spill are also dependent upon the duration of the exposure to the components in the oil. Bivalves and crustaceans located in intertidal or shallow sub tidal areas are particularly vulnerable to contamination from some of the lighter, more aromatic, compounds in oil.

**Fish or Other Seafood Products – Sub lethal Effects**

Fish or other seafood products can become tainted, defined as giving the product a petroleum taste or smell. Although it is essentially non-harmful to consumers, it can affect the marketability of the product and is most common in bi-valve molluscs and other filter feeding, sedentary animals (marine bottom-dwelling animals attached to the substrate). There are no set threshold values to determine if a product is tainted, subsequently it cannot be determined through chemical analysis, but only through taste (organoleptic testing). In the event of an oil spill, if there are signs of shellfish / fish oil tainting or contamination, any resultant imposed authority restrictions on fishing activities could result in detrimental impacts upon local fishers.

**Damage to Fishing Gear**

It is considered that the risks of damage and contamination to fishing gear is very low, given that following a spillage, any affected areas would be avoided by fishing vessels, whilst MGO or MDO spillages are expected to be rapidly dispersed.

**Fisheries - Mitigation**

The maritime risk assessment and oil spill modelling as presented in Appendix 19.2 has established that Project construction activities do not present a major risk of oil spills and that the fuels in question, if spilt, would evaporate to a significant degree with the remainder being naturally dispersed in the water column by wave action within a few days of being spilled. This reduces the potential for adverse impacts upon local fisheries and the local and regional fisheries industry. In addition, as indicated in Section 19.7.1.2, contractors and operators of vessels working on behalf of South Stream Transport will be required to develop and implement an Oil Spill Prevention and Response Plan. Vessels will also need to operate in compliance with MARPOL regulations on oil spill prevention and response and are required to prepare SOPEP and SMPEP as applicable for each vessel (Ref. 19.3; Ref. 19.4). The SOPEPs will specify the control and response measures that have to be available on board every vessel to respond to a spill that does not require external intervention. Such measures will further limit the potential for adverse impacts upon local fisheries and the local and regional fisheries industry.
South Stream Transport will ensure that contracts with vessel owners include appropriate oil spill compensation provisions to cover such potential socio-economic oil spill consequences.

### 19.7.2 Commissioning and Operational Phase – Marine Sections

#### 19.7.2.1 Events Identification

During the Operational Phase (including Commissioning) of the Project unplanned events at sea may occur as a result of accidental leakages of natural gas from the subsea pipeline, as well as the introduction of invasive species by maintenance vessels.

Table 19.8 below lists the activities that are discussed in this section that could result in an unplanned event, describes the events, and the receptors that could be affected.

<table>

</tr>
</tbody>
</table>

In order to assist in the risk assessment process, a Shipping Risk Report was prepared for the Project (Ref. 19.5). The report considers the risks to the marine pipelines posed by shipping in the Black Sea. The following shipping hazards were identified as posing a potential risk to the integrity of the pipelines:

- **Ship sinking onto and damaging the pipeline**: The risks of ship sinking damaging the pipelines can occur along the entire pipeline route, although there is only a risk when the ship is large enough to cause damage to the pipeline;

- **Ship grounding onto the pipeline**: Ship grounding becomes a risk when the ship is large or heavy enough to cause damage to the pipeline. In addition, grounding can only occur in shallow water. Based on the main characteristics of ships, ships are generally at risk from grounding when navigating in water with a depth of less than 18 m. Given that the pipeline at the Russian nearshore will be buried in such water depths, the risks of pipeline damage by ship grounding is considered to be negligible (Ref. 19.5);

- **Ship anchoring damaging the pipeline**: Risks associated with anchoring in the vicinity of the pipeline are two-fold:
o **Anchor drop**: An anchor, with impact energy sufficient to create significant damage, can be dropped directly on the pipeline; or

o **Anchor drag**: An anchor dropped in the vicinity of the pipeline can subsequently be dragged interacting with the pipeline; and

- **Ships dropping objects (such as containers) onto the pipeline**: The risks of ships dropping objects into the pipeline can occur along the entire pipeline route. When a container hits the top of a pipeline, the result can be a dent in a bare steel pipeline or, when the pipeline has concrete weight coating, a cracked coating possibly combined with a dent in the steel pipeline.

The hazards as detailed above have the potential to result in pipeline damage / failure, which could result in the release of gas (and potential subsequent fire) from the sub-sea pipeline which has the potential to impact upon the environment and human health receptors. However, due to the pipeline engineering design standards being applied which aim to minimise the potential for pipeline rupture and associated gas leakages (see Section 19.6.2.2), and the use of exclusion zones along the offshore pipeline (see Section 5.6.7), the potential for such a safety incident from an offshore pipeline is remote.

It is noted that there is a risk of encountering geohazards along the offshore pipeline route. Geohazards associated with the offshore environment include seismic activity, soft sediments, shallow gas and gas seeps. Appendix 19.3 presents details of potential marine geohazards and the resultant pipeline design responses.

For a fire incident following a gas leakage to impact upon human health receptors, it would require a pipeline failure and gas leakage, followed by ignition at the sea surface in conjunction with a passing vessel. The most likely occurrence of this type of event would be where an object such as a container or the vessel itself, causes an impact failure by sinking on the pipeline as detailed above. The potential resultant impacts associated with environmental and human health receptors are discussed below.

Some unplanned events have been excluded from the assessment undertaken in this section as they are not expected to lead to significant environmental and socio-economic impacts. Unplanned events that have been excluded from discussion are:

- **Pipeline repairs / salvage as associated with unplanned events**: following unplanned events there may be the need for pipeline salvage / repair works. It is considered that such activities would be similar to pipeline construction activities. Under such circumstances, salvage / remedial works would be undertaken in accordance with GIIP which would limit the potential for significant environmental impacts; and

- **Maritime vessel collisions and resultant oil spillages**: given the low volume of survey and maintenance vessels anticipated to be used during the Operational Phase, it is considered that the risks of collisions and oil spillages is so remote that is can be scoped out of the assessment. Maritime vessels operated on behalf of South Stream Transport will be operated in accordance with GIIP which would limit the potential for spillages and associated significant environmental impacts, whilst Oil Spill Prevention and Response Plans will still be required to limit the potential for oil spills and resultant impacts.
19.7.2.2 Potential Impacts to Environmental Receptors

Invasive Species

Maritime vessel operations during the Operational Phase will be limited to the periodic use of maintenance and monitoring vessels (see Chapter 5 Project Description). During routine monitoring or in the event that repairs are necessary, there is potential for vessels to be used from outside of the Black Sea. As such, there is the potential for such vessels to inadvertently introduce invasive alien species to the marine environment in the same manner as described in Section 19.7.1.2 for the Construction Phase.

The potential environmental consequences of introducing invasive species are considered in Section 19.7.1.2. Given the limited maritime vessel use required during the Operational Phase, it is considered that the risks of such events occurring is less than during the Construction Phase.

The mitigation measures as detailed in Section 19.7.1.2 will be applied during the Operational Phase in order to minimise risks to the marine environment from the inadvertent introduction of invasive species from maritime vessels.

Gas Leakages

Any gas released from a damaged sub-sea pipeline would rise through the water column as a plume of gas bubbles. On reaching the sea surface, the gas would disperse into the air.

As detailed in Section 19.6.2.2, gas releases into the atmosphere would not result in acute environmental impacts. The impacts would be chronic through the addition of greenhouse gases to the atmosphere. Such gas releases would not be significant in terms of increasing overall Russian Federation greenhouse gas emissions, although methane levels at the release site would be temporarily elevated which could locally impact upon any present marine ecology, including seabirds.

Gas passage through the water column could also impact upon marine organisms (such as fish and marine benthos), resulting in potential acute or chronic impacts depending upon exposure levels and environmental conditions (e.g. water temperature, dissolved oxygen) (Ref. 19.6). Gas is able to rapidly penetrate into marine organisms (especially through the gills) and disturb the main functional systems (respiration, nervous system, blood formation, enzyme activity, and others). Initially, organisms such as fish may exhibit behavioural symptoms such as fish excitement, increased activity, scattering in the water. Thereafter, further exposure can lead to symptoms of poisoning. As with most toxicants, early life stages are most vulnerable to effects.

Section 19.6.2.2 provides details of the measures included in the pipeline design that aim to minimise the potential for uncontrolled gas releases from the pipeline, and the actions that would be taken in the event of an unplanned gas release (to be defined in the contractor Emergency Response Plans).

Of note is that a number of Project design control measures have been identified to reduce the risk of geohazards impacting upon the integrity of the offshore pipeline which could result in gas leakages (refer to Appendix 19.3). During the Development Phase, geohazard mapping was undertaken to facilitate the pipeline route alignment as based on marine survey findings and
associated engineering assessments (Ref. 19.9 and 19.10). In addition, the occurrence of mass movements triggered by events such as earthquakes was taken into account during the pipeline design process (Ref. 19.8). As detailed in Section 5.2.6.1, the pipelines will be designed in accordance with DNV-OS-F101 which considers standards for geohazard risk analyses. The pipeline design thus aims to minimise the occurrence of the unplanned gas releases following pipeline damage by unplanned events, whilst the Emergency Preparedness and Response Plan will further minimize the potential risks and environmental consequences of such events.

### 19.7.2.3 Potential Impacts to Socio-Economic Receptors and Community Health

**Invasive Species**

As detailed in Section 19.7.2.1, during the Operational Phase, there remains a low level risk that vessels from outside of the Black Sea will be used for pipeline repairs. In order to minimise risks to commercially important fish populations from the inadvertent introduction of invasive species from maritime vessels (as described in Section 19.7.1.3), the mitigation measures as detailed in Section 19.7.1.2 will be applied during the Operational Phase.

**Gas Leakages and Fire**

Should the marine pipeline rupture via the unplanned events as detailed in Section 19.7.2.1, gas would rise through the water column and disperse into the air.

Short-term human exposure to low concentrations of natural gas may cause headaches, dizziness, drowsiness, nausea and vomiting. High vapour concentration may lead to unconsciousness due to the absence of oxygen. Asphyxiation of any person present on a ship within the gas cloud was assumed to be a very unlikely scenario by the Shipping Risk Report (Ref. 19.5) as the gas concentration in the air would rapidly decrease to below harmful levels.

Natural gas is extremely flammable, forming a flammable mixture at a concentration of approximately 5% gas in air (by volume). In the unlikely event of a gas leakage, the risk to community facilities and health is associated with fire and explosion rather than gas exposure. Ignition of the gas cloud by an ignition source present on a ship in the gas cloud could result in a flash fire and harm, including potential ship’s crew fatalities as well as result in vessel damage. For this risk analysis it was assumed that:

- Ships having performed anchoring operations that interact with the pipelines will be present in the gas cloud as they will have stopped or be close by; and
- Ships sinking or dropping containers on the pipelines would not be present in the gas cloud.

In order to minimise such risks to ships, the pipeline design standards as detailed in Section 5.2.6.1 aim to minimise the potential for pipeline rupture and associated gas leakages, and thus minimise the potential socio-economic implications. In addition, in order to minimise potential damage to the subsea pipelines (e.g. dragged anchors, fishing gear etc.), as well as minimise the risks to third party vessel occupants, exclusion zones will be put in place along the pipeline route during the Operational Phase. As detailed in Section 5.6.7, it is anticipated that the exclusion zone will extend to 0.5 km either side of the outermost pipelines from the microtunnel.
exit pit until the Russian / Turkish EEZ boundary (except for a section on the Russian continental slope where the pipelines diverge into two groups of two) (refer to Figure 5.41).

Section 19.7.2.2 also indicates that gas leakages can impact upon marine fish, although any such events are unlikely to result in widespread impacts upon fisheries. Following a gas leakage, the main impact may be the temporary exclusion of fishing vessels from potentially affected areas.

19.7.3 Decommissioning

The approach presented in Section 19.6.3 as related to the potential for unplanned events during the decommissioning of onshore pipelines are also applicable to the decommissioning of the marine pipeline. Thus as part of the decommissioning planning programme, the potential for unplanned events will be considered and appropriate mitigation and management measures put in place to reduce risks and consequences to the surrounding environmental and local community receptors.

20 Cumulative Impact Assessment

20.1 Introduction

While the impacts of an individual project may be judged to be acceptable, there is also a need
to consider the potential for a project’s impacts to interact with impacts associated with other
developments – so called “cumulative” impacts.

This chapter presents a cumulative impact assessment (CIA) for the Project. The sections
herein present details of applicable CIA guidance, the adopted CIA methodology, CIA scoping
and impact assessment. The CIA takes account of planned and reasonably defined
developments in the vicinity of the Project.

20.2 Definitions

International Finance Corporation (IFC) Performance Standard (PS) 1 (Ref. 20.1) defines
cumulative impacts as:

“impacts that result from the incremental impact, on areas or resources used or directly
impacted by the project, from other existing, planned or reasonably defined developments at
the time the risks and impacts identification process is conducted”.

The impacts of the Project thus need to be considered in conjunction with the potential impacts
from other future developments or activities that are planned and reasonably and are located
within a geographical scope where potential environmental and social interactions could act
together with the Project to create a more (or less) significant overall impact.

20.3 CIA Guidance

20.3.1 International Finance Corporation (IFC) Guidance

IFC PS 1: Assessment and Management of Environmental and Social Risks and Impacts
(Ref. 20.1) recognises that in some instances, developers need to consider cumulative impacts
in their environmental and social impact and risk identification and management process.

PS 1 states that the impact and risk identification process:

“will take into account the findings and conclusions of related and applicable plans, studies, or
assessments prepared by relevant government authorities or other parties that are directly
related to the project and its area of influence” including “master economic development plans,
country or regional plans, feasibility studies, alternatives analyses, and cumulative, regional,
sectoral, or strategic environmental assessments where relevant”.

Furthermore, it goes on to state that:

“the client can take these into account by focusing on the project’s incremental contribution to
selected impacts generally recognized as important on the basis of scientific concern or
concerns from the Affected Communities within the area addressed by these larger scope regional studies or cumulative assessments”.

In order to provide guidance on undertaking a CIA, IFC released a guidance note in August 2013 titled “Cumulative Impact Assessment and Management – Guidance for the Private Sector in Emerging Markets” (Ref. 20.2). This guidance note uses the concept of Valued Environmental and Social Components (VECs), these being VECs being environmental and social attributes that are considered to be important in assessing risk1, which can include:

- Physical features;
- Wildlife populations;
- Environmental processes;
- Ecosystem conditions (e.g. biodiversity);
- Social conditions (e.g. health, economics); or
- Cultural aspects.

The IFC guidance note provides a six step process for assessing the potential for cumulative impacts upon VECs as follows:

- Scoping Phase I identifying – VECs, spatial and temporal boundaries;
- Scoping Phase II – other activities and environmental drivers;
- Establish information on the baseline status of VECs;
- Assess cumulative impacts on VECs;
- Assess significance of predicted cumulative impacts; and
- Management of cumulative impacts – design and implementation.

This CIA has used the IFC guidance note as a framework for assessing potential cumulative impacts associated with the Project and reasonably defined developments.

20.4 CIA Methodology

The CIA methodology adopted has been defined taking into account the six step process as detailed in the IFC CIA guidance note (Ref. 20.2) (Section 20.3.1). The bullet points presented below detail the activities that have been undertaken as part of this CIA:

- **Scoping Phase I**: this entailed defining which VECs needed to be included within the CIA taking into account the characteristics of the Project and the prevailing environmental and social conditions within areas that are potentially impacted by the Project. The VEC identification process has been assisted through the completion of engagement activities

---

1 VECs are considered to be equivalent to “receptors” as defined in Chapter 3 Impact Assessment Methodology.
with applicable stakeholders. This phase of the assessment has also required setting
temporal and spatial boundaries of the CIA for specific VECs;

- **Scoping Phase II**: this required the identification of other projects or human activities
  that could potentially impact upon defined VECs that could result in cumulative impacts. An
  analysis has then been undertaken which aims to define those development projects that
  are scoped into the CIA given their potential ability to generate a cumulative impact
  associated with the Project (due to temporal / spatial interactions with the Project);

- **Establish Information on the Baseline Status of VECs**: defining the baseline
  characteristics of VECs is an important stage in the CIA process, as this identifies their
  sensitivity to change. Note that relevant baseline information has been provided in Chapters
  7 to 18 of this ESIA Report and is not reproduced here; and

- **Assess Cumulative Impacts Upon VECs**: taking into account the Project's predicted
  impacts upon identified VECs, an assessment has been undertaken to evaluate the ability of
  the Project to interact with other planned or reasonably defined developments in such a
  manner that gives rise to a cumulative impact (where the temporal and spatial influences
  may coincide). Note that the assessment presented in this chapter only considers the
  residual impacts arising from the Project (i.e. impacts following the application of mitigation
  measures as detailed in this ESIA Report). It follows that the chapter only considers those
  VECs that will experience any degree of residual impact associated with the Project. Thus
  VECs, for which there is a Project residual impact that is deemed to be insignificant in this
  ESIA, do not need to be included in the CIA in accordance with IFC CIA guidance note
  (Ref. 20.2) (see Table 20.1).

**Table 20.1 Scoping Criteria for Inclusion of VECs in the CIA**

<table>

<th>Moderate</th>
<th>High</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scoped out of CIA</td>
<td>Reviewed for potential cumulative impacts</td>
<td>Scoped into CIA</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As detailed in Table 20.1, where VEC residual impacts are defined as being Moderate or
High Adverse, these are scoped into the CIA. Where VEC residual impacts are assessed as
being Not Significant, these can be scoped out of the CIA (given that such VECs are either
of negligible sensitivity or impact magnitudes are negligible – refer to impact significance
matrix Table 3.3 in **Chapter 3 Impact Assessment Methodology**). For VEC residual
impacts that are defined as being of Low Adverse, the applicable VECs have been subject to
further evaluation to see if there is scope for cumulative impacts to be generated.

- **Assess Significance of Predicted Cumulative Impacts**: significant cumulative impacts
  have been evaluated as far as possible using the impact significance matrix presented in
  **Chapter 3 Impact Assessment Methodology**. Note that this has been possible only
  where the magnitude of impacts is capable of definition, for example, through readily
  accessible Environmental Impact Assessment (EIA) / ESIA reports or project
documentation). It is beyond the reasonable scope of this ESIA Report to undertake an
impact assessment of other developments that may occur within the vicinity of the Project. Where such information is not available, the assessment of potential cumulative impacts has been qualitative, and has relied upon professional judgement using the impact significance definitions described in Chapter 3 Impact Assessment Methodology. The assessment has not considered unplanned events as discussed in Chapter 19 Unplanned Events; and

- **Management of Cumulative Impacts – Design and Implementation:** should the CIA indicate that there is a potential cumulative impact which is of Moderate or High significance, the need for additional mitigation or management actions (or monitoring) (beyond those which are targeted at Project-induced impacts as reported within this ESIA Report) has been specified.

### 20.5 CIA Scoping Phase I: VECs, Temporal and Spatial Boundaries

#### 20.5.1 VEC Identification

The ESIA Report considers the potential Project impacts across a wide range of VECs. These VECs have been defined by taking into account the prevailing environmental and social conditions in the Project Area, and the ability of the Project to impact upon these resources (during all Phases of the Project). Consultation with relevant stakeholders has been a key component of the environmental and social resource identification process – stakeholder engagement activities are detailed in Chapter 6 Stakeholder Engagement.

A summary of the VECs (receptors) that have been considered within this ESIA Report, and thus within this CIA, comprise the following:

- Physical (i.e. non-living environmental components, including air quality, water bodies, landscapes, terrestrial soils, marine sediments and geology);
- Marine ecology (i.e. marine habitat, flora and fauna);
- Terrestrial ecology (i.e. terrestrial habitat, flora and fauna); and
- Human (i.e. landowners and residents of local communities, local economy, marine users, cultural heritage).

#### 20.5.2 Temporal and Spatial Boundaries

The CIA temporal boundary covers the Project Construction and Pre-Commissioning Phase and the early Operational Phase. However, the degree of uncertainty increases the further into the future the assessment extends. As such, potential cumulative impacts during the Decommissioning Phase have been scoped out of the assessment given that the decommissioning programme is uncertain and will be developed during the Operation Phase of the Project.

A review, and relevant studies if necessary, will be undertaken during the Operational Phase to confirm that the planned decommissioning activities are the most appropriate to the prevailing
circumstances. The review would outline management controls and demonstrate that the decommissioning activities will not cause unacceptable cumulative environmental and social impacts should there be other developments in the vicinity of the proposed decommissioning works.

The geographic boundaries of the CIA have been defined taking into account the Project characteristics (Chapter 5 Project Description) and the assessment areas applied to defined VECs as included within the various technical assessments (Chapters 8 to 18) within this ESIA Report. A flexible approach has been maintained, such that the boundaries of the assessment vary depending on the characteristics of the potentially impacted VEC. The geographic boundary thus varies from the space occupied by a small VEC feature (e.g. a discrete feature of cultural heritage value) to a large geographic region or habitat within which a particular VEC occurs (e.g. habitat occupied by a protected species). The spatial extent of relevant VECs is detailed in the various technical assessments as presented within this ESIA Report.

20.5.3 Further Evaluation of Low Significance Impact to VECs

Table 20.2 presents a summary of the impact assessment as reported within this ESIA Report and identifies residual impacts on defined VECs during the Project Construction and Pre-Commissioning and Operational Phases.

As per the IFC guidance note (Ref. 20.2), this CIA considers those VECs that will be impacted by the Project with any degree of residual impact – thus VECs for which there is an impact that is deemed to be Not Significant do not need to be included and can be scoped out of this CIA. Where the Project residual impact significance is defined to be Moderate or High, the applicable VEC is scoped into the CIA. Residual impacts defined as Low have been subject to further evaluation in order to see if there is potential for cumulative impacts to be generated. Text highlighted in grey in Table 20.2 indicates that the VEC and associated impact source are scoped into the CIA on the basis of a High, Moderate or Low (following further evaluation) residual impact.

Table 20.2 illustrates the VECs and impact sources scoped into the CIA on the basis of a Moderate Adverse residual impact, which are:

- Construction Phase impacts upon the prevailing landscape character and visually sensitive human receptors;
- Reduced residential amenity for residents in local communities, specifically northeast Varvarovka, during the Construction and Pre-Commissioning Phase due to potential combined noise and visual impacts;
- Construction Phase impacts upon marine cultural heritage resources; and
- Waste disposal of material at the Alfa Landfill.

These issues are further considered in Section 20.7 together with discussion of selected VECs which experience Low Adverse residual impacts, in order to explore the potential for cumulative impacts. Section 20.7 also includes, on the basis of professional judgement, some VECs which experience a Not Significant residual impact.

20.6 CIA Scoping Phase II: Other Developments

20.6.1 Introduction

This section defines the planned and reasonably defined developments in the vicinity of the Project. If the Project is able to interact with such developments (temporally and / or spatially), the Project may be able to exert a potential cumulative impact.

Information has been obtained from the Project stakeholder engagement and consultation process (Chapter 6 Stakeholder Engagement), in particular information has been obtained from local, regional, governmental organisations and from a review of the open literature.

20.6.2 Development Proposals

The following planned and reasonably defined development proposals have been identified in the vicinity of the Project:

- Project connection with South Stream Pipeline (Turkish Sector) at the Russian / Turkish EEZ border;
- The Russkaya compressor station (CS) and associated pipelines (Ref. 20.3 and Ref. 20.4);
- Other developments as included in the Anapa District Growth Development Plan (GDP) (Ref. 20.5);
- The Residence of Utrish development (Ref. 20.6);
- The Zapovedny (Reserved) development (Ref. 20.6);
- The Club Village Chateau development (Ref. 20.6);
- The "Clearing in the Woods" ("Lesnaya Polyana") development (Ref. 20.6 and Ref. 20.7);
- Rosneft oil and gas exploration activities (Ref. 20.8);
- Other developments in eastern Sukko (Ref. 20.9); and
- The Anapolis development (Ref. 20.9).

Other than the Rosneft oil and gas exploration activities, there are no known marine development proposals outside of the Project to develop new uses or intensify existing uses in either the nearshore or offshore sections of the Project Area.

Figure 20.1 shows the location of the Russkaya CS and associated pipelines and the potential residential developments at Lesnaya Polyana (labelled A in Figure 20.1), Utrish (labelled B in Figure 20.1), Zapovedny (labelled C in Figure 20.1), Club Village Chateau (labelled G in Figure 20.1) and the Anapolis development (labelled D in Figure 20.1). Figure 20.2 shows indicative locations of conceptual developments as contained within the Anapa District GDP (also refer to Figure 14.10). These proposed developments are discussed in the sections below.
20.6.2.1 Project Connection with South Stream Pipeline at the Russian / Turkish EEZ Border

The South Stream Offshore Pipeline will traverse the Black sea via the Russia, Turkey and Bulgaria EEZs. The Project (Russian Sector) will therefore interface with the South Stream Offshore Pipeline (Turkish Sector) located in the Turkish EEZ. During the Construction and Pre-Commissioning Phase, activities taking place within Turkish waters will be similar to those taking place in the Russian offshore areas, including:

- Mobilisation of vessels to and from site and vessel movements within construction spread;
- Perform pre-lay, as-laid, and as-built ROV surveys etc.;
- Delivery of fuel, pipe and other supplies including hazardous substances to pipe-laying vessel by supply vessel;
- Storage of fuel and other hazardous materials;
- Refuelling of vessels, plant and machinery;
- Helicopter operations for crew changes;
- Maintenance of plant and machinery;
- Waste generation from vessel operations;
- Use of fresh water maker / desalination unit and vessel cooling water system; and
- Night time working.

During the Operational Phase, the South Stream Offshore Pipeline - Turkish Sector, in Turkish waters, will be subject to the same maintenance regime as being applied to the deep water pipelines in Russia (refer to Chapter 5 Project Description).

20.6.2.2 Russkaya Compressor Station (CS) and Pipelines

The Project landfall facilities will be connected to the Russkaya CS via four 3.2 kilometre (km) long onshore pipelines (see Figure 20.1). The Russkaya CS, and the four connecting pipelines, are being developed by Gazprom Invest as part of the “Expansion of the UGS to provide gas to South Stream pipeline” (UGS - United Gas Supply System) and do not form part of the Project. However, the Russkaya CS and the four connecting pipelines have been defined as associated facilities (refer to Chapter 5 Project Description).

The Russkaya CS will be located in the Anapa administrative district of the Krasnodar Region on a green field site and in a relatively isolated location. The village of Gai Kodzor is located approximately 1.2 km northeast of the Russkaya CS site, whilst Sukko is located approximately

---

2 OECD Common Approaches (Ref. 20.13) defines associated facilities as being “facilities that are not a component of the project but that would not be constructed or expanded if the project did not exist and on whose existence the viability of the project depends; such facilities may be funded, owned, managed, constructed and operated by the buyer and/or project sponsor or separately from the project.”
2.9 km to the south and Varvarovka is approximately 4.25 km to the west of the Russkaya CS site.

The construction of the Russkaya CS forms part of the first stage (Western corridor) of the UGS expansion, which is expected to be operational in 2016. The capacity of the Russkaya CS will be increased during the second stage (Eastern corridor) of the UGS expansion, which is expected to be commissioned and operational in 2019. A storage area for material and equipment, the Materials and Equipment Depot (MED), will also be established during this second stage.

The Russkaya CS includes the following (Ref. 20.3 and Ref. 20.4) main technical equipment within the site limit:

- Input pipelines with gas inlet piping machinery stations;
- Gas treatment units;
- Compressor works with gas pumping unit (GPU) of unit rating 25 - 50 MW and individual gas air cooling units; and
- Gas flow rate metering unit (GFMU).

The Russkaya CS development footprint has been estimated based upon data as presented in the Russkaya EIA documentation (Ref. 20.3 and Ref. 20.4) as follows:

- The compressor station construction footprint is assessed to be approximately 52 ha;
- Assuming a 120 m wide construction corridor for the 3.2 km long pipelines connecting the Russkaya CS with the South Stream Transport landfall facilities, the pipeline Right-of-Way (RoW) equates to a construction area of approximately 38.7 ha; and
- The construction footprint for the Gazprom Invest permanent access road is estimated to be approximately 4.5 ha.

In addition to the above, an area of approximately 16.1 ha has been assumed to be required for a temporary construction works area (located to the northwest of the Russkaya CS construction footprint).

Given the above, the total construction footprint of the Russkaya CS development is assessed to be approximately 111.3 ha.

In addition to the above, the Russkaya CS includes a tie in with the trunk gas pipeline with a PIG receiver, a gas processing unit, emergency diesel power stations, auxiliary power supply stations, a production and operations building, a machinery and repair shop with reserve motor storage, a boiler room, a gas-meter station, a thermal waste-decontamination unit, tanks with oil products, a road vehicle car park and washing area and a sewage treatment plant.

The MED will meet Russkaya CS operational requirements by acting as a storage area for materials and equipment and will be located 290 m to the north northwest of the Russkaya CS. The MED will include an entry area with changing rooms, heated warehouse, cooled warehouse, open storage area, automatic diesel power station (ADPS), diesel storage tank and local treatment facilities for rainwater.
The main construction period for the Russkaya CS is predicted to last for 34 months. It is noted that early works and site preparation activities for the Russkaya CS commenced in early 2013. The first phase of the main construction period is anticipated to commence in January 2014 and last 22 months until October 2015. The second phase of construction is proposed to start in May 2015 and last 18 months until October 2016. A six day working week and ten hour working day are likely to be adopted during the construction phase.

The construction phase of the Russkaya CS will consist of both offsite and on-site preparatory work. The offsite preparatory work will include activities such as the construction of the planned access road, preparation of a temporary construction compound including accommodation, the delivery of pre-fabricated buildings for storage and household needs, the laying of temporary utility lines and the repair or upgrade of existing roads for use during construction. The on-site preparatory work will include temporary areas for erecting cranes, protection of underground utilities with reinforced concrete slabs, construction of storage and assembly areas, arrangement of temporary site utilities, construction of temporary pedestrian paths and lighting of the construction site. Activities involved in the construction of the Russkaya CS include excavation, piling, laying of utilities, erection of above ground structures, installation of process piping and equipment, internal plumbing work, electrical work and commissioning.

The potential environmental impacts associated with the development of the Russkaya CS are reported in the development EIA documentation (Ref. 20.3 and Ref. 20.4). As indicated above, the Russkaya CS construction programme will in part overlap with proposed Project construction works.

Given its definition as an associated facility, key findings of the Russkaya EIA are detailed in Appendix 20.1. The Appendix also presents South Stream Transport’s commitments in relation to Russkaya CS as an associated facility. The commitments will be implemented through the HSSE Interface Management Procedure for Gazprom Invest which is part of South Stream Transport’s HSSE Integrated Management System.

20.6.2.3 Rosneft Oil and Gas Exploration

Rosneft is a Russian oil and gas company that is planning to develop a number of concession blocks within the Black Sea off the Russian coastline, namely: the Tuapse Trough, West-Chernomorsky and the South-Chernomorsky offshore areas (see Figure 20.3).

According to Rosneft’s 2012 Annual Report (Ref. 20.8), the Tuapse Trough has a potential recoverable resource estimated at approximately 1.2 billion tonnes of oil equivalent and that 3D seismic work totalling approximately 4,200 km² was completed in 2012, whilst 3D seismic data obtained earlier have been processed. The West-Chernomorsky area has an estimated recoverable resource equal to approximately 1.4 billion tonnes of oil equivalent within a block area of approximately 9,000 km². Rosneft has carried out seismic works to study the area and has identified six promising formations. Rosneft press releases (Ref. 20.10) report that two exploration wells are to be drilled in 2015 - 2016 in line with license obligations. The South-Chernomorsky area has a recoverable resource of approximately 0.47 billion tonnes of oil equivalent and the area has been subject to 2D seismic surveying in 2012.
South Stream Transport has met with Rosneft to discuss potential interactions between Rosneft’s oil and gas exploration activities and the Project. However, further information detailing Rosneft’s exploration locations and programme are not available at the time of writing.

### 20.6.2.4 The Clearing in the Woods (“Lesnaya Polyana”)

This is a proposed 16.5 hectare residential development with approximately 160 land plots that is currently under construction and essentially an extension of the town of Varvarovka (Figure 20.1 – development A) (Ref. 20.6). The development site is located approximately 500 m northwest of the microtunnel entry points and 1.5 km southwest of the landfall facilities.

It is understood from the site developer (February 2014 Ref. 20.11) that construction of the access roads and site levelling have been completed, whilst works are on-going with regard to the water supply. It is also understood from the developer that some land plots have been sold, but that housing construction activities are planned this year and continue for the next two to three years. There is thus the potential for the development construction works to overlap with the construction works associated with the Project (Chapter 14 Socio-Economics). The development may also be defined as a sensitive receptor if some works are completed and properties are inhabited prior to the start of the Construction and Pre-Commissioning Phase of the Project, although this is considered unlikely to happen given the status of the development proposals.

### 20.6.2.5 The Residence of Utrish Development

This is a potential residential development in the settlement of Sukko covering an area of approximately 16 hectares, located approximately 2.55 km southeast of the microtunnelling point (Figure 20.1 – development B). This housing complex consists of (Ref. 20.6):

- 14 houses with a small number of apartments;
- 46 town houses (terraced houses);
- 44 cottages; and
- Commercial areas and social infrastructure.

It is understood from the developer (February 2014 Ref. 20.11) that four to five houses have been sold and are now occupied, whilst 20 to 25 townhouses have also been sold. The development’s proposed construction phase runs from 2011 – 2015 and thus there is a potential for on-going construction works to overlap with those of the Project.

### 20.6.2.6 The Zapovedny (Reserved) Development

This residential development comprises approximately 114 residential dwellings located in the southern part of Sukko (area of approximately 11.5 hectares), approximately 3.5 km east-southeast of the microtunnelling point (Figure 20.1 – development C) (Ref. 20.6). It is understood from the site developer (February 2014 Ref. 20.11) that the development road system has been completed and that works are starting with regard to the electricity supply. There is thus the potential that on-going construction works overlap with those of the Project.
20.6.2.7 Other Developments in Eastern Sukko

Other potential developments in eastern Sukko include the following (Ref. 20.9) (see Figure 20.1):

- Children’s Entertainment Park covering an area of approximately 89 ha which may be developed before 2019 (labelled E in Figure 20.1); and

- Resort-Residential District “Gornoye Ozero” which would comprise apartments and low-rise houses, social infrastructure (educational, health care, sport and leisure facilities) and commercial facilities (e.g. shopping centre, restaurants, hotels etc.) (labelled F in Figure 20.1). This particular development will extend over an area of approximately 240 ha. It is understood from the developer (February 2014 Ref. 20.11) that the project is at the design stage and that the aim is to have the facility fully developed before 2020.

The programme for these potential developments is uncertain, although it is considered most likely that if developed, they would be constructed after the Project Construction and Pre-Commissioning Phase.

20.6.2.8 Club Village Chateau

The Club Village Chateau development (see Figure 20.1) involves the development of approximately 45 chateaus. These chateaus will be constructed within an area of existing vineyards such that each chateau will be located within a land plot which has its own private vineyard (Ref. 20.6).

The development plot has a total area of approximately 83 ha, although the construction works are estimated to impact upon approximately 20% of the total development footprint (calculated from a review of the proposed development layout proposals) thus impacting upon an area of approximately 16.6 ha.

It is understood from the developer (February 2014 Ref. 20.11) that the development is currently on hold and that works will only proceed following completion of the Project Construction Phase given that the road which passes through the development plot will be used as a Project access road.

20.6.2.9 The Anapolis Development

This is a proposed mixed use district development that includes residential properties, commercial facilities, hotels and associated infrastructure. The development site covers an area of approximately 66.7 hectares, and is located approximately 350 m south of the Pipeline alignment (Figure 20.1) (Ref. 20.9). It is understood from the site developer (February 2014 Ref. 20.11) that some construction works are planned to start this year, although this depends upon progress in terms of water and electricity connections (understood to be planned for 2015). There is thus the potential that future construction works could overlap with those of the Project.
20.6.2.10 Anapa GDP Proposals

The Anapa GDP (Ref. 20.5) contains potential development proposals that may be developed over the next 20 years. These development proposals are at the conceptual planning stage and thus there is uncertainty as to when they will occur and their associated development footprints. Of note to this assessment is reference to the following development proposals (Figure 20.2; also refer to Figure 14.10):

- Planned expansion of northern Gai Kodzor in areas free from existing structures that are within the existing boundaries of the village (approximately 4.5 km northeast of the landfall facilities);
- The low-rise residential development in the central, western and southern parts of Supsekh making use of undeveloped land within the settlement and 39 hectares of agricultural land (located approximately 3.5 km northwest of the Pipeline). The development may also include new secondary education schools, kindergartens, district hospital, out-patient clinic, emergency medical service department, fire station, shopping and routine services facilities and sports facilities;
- The allocation of shopping, public catering and roadside service facilities along the Anapa to Sukko motorway on the southern outskirts of the village of Supsekh;
- Development in the southern part Varvarovka. The design includes a low-rise residential estate, a kindergarten, a clinic and a new motorway to start in the region of the Supsekh cemetery and run parallel to the coastline, along Marusenkov Gaping to the Anapa to Sukko motorway; and
- Development of Sukko within the undeveloped areas within the existing village, including residential areas in the valley on the right bank of the Sukko River, in the central part of the village and to the south of Gornay Street (approximately 2.55 km southeast of the Project). The development proposals also include a school, kindergarten, medical clinic, centre for spa services, and the construction of a waterfront pedestrian area with parks and landscaping along the Sukko River, plus construction of a 3 km beach strip with waterfront facilities and relevant infrastructure (existing beach length is approximately 650 m long).

20.6.3 Development Proposal CIA Analysis

Section 20.6.2 above defines the planned and reasonably foreseeable or defined development proposals in the vicinity of the Project. An analysis has been undertaken of development proposal features (programme, distance from the Project activities, development footprint characteristics) in order to ascertain the Project's potential to contribute to a cumulative impact during its Construction and Pre-Commissioning and Operational Phases. This analysis is presented in Table 20.3 and details which development proposals have been scoped in and out of the CIA (i.e. developments scoped out of the assessment are considered to not have the ability to generate a significant cumulative impact as associated with the Project) or where development proposals have a high degree of uncertainty or are undefined such that the potential for cumulative impacts cannot be appropriately assessed.

On the basis of the development cumulative impact analysis as detailed in Table 20.3, the following developments have been scoped into the CIA:

- Russkaya CS and associated pipelines;
- Lesnaya Polyana;
- Club Village Chateau; and
- Anapolis mixed use development.

Other developments have been scoped out of the CIA on the basis that:

- The temporal or spatial interactions with the Project are such that significant adverse cumulative impacts would be avoided;
- The development proposals are only at the conceptual stage; or
- There is lack of information available to undertake a meaningful assessment.

3 The Lesnaya Polyana, Club Village Chateau, and the Anapolis mixed use developments are all being progressed by Fund Yug properties.

<td>Scoped out</td>
</tr>
</tbody>
</table>

Based on the current Project programme, construction activities will be taking place in Russian and Turkish waters at the same time for a duration of approximately 171 days. The construction spreads in Turkey and Russia will be travelling at the same speed, whilst there will be at least 470 km between these spreads at any given time. Given this distance between the construction spreads and given the limited range of impacts that are associated with the works (such as underwater noise impacts upon marine mammals and fish), it is considered that concurrent activities within Turkey and Russian offshore areas will not be able to generate any significant cumulative impacts. Similarly any concurrent Operational Phase maintenance activities taking place are not anticipated to generate any significant cumulative impacts.

Continued...
Development | Interaction with Project | Scoped In / Out of CIA
---|---|---
Russkaya CS (see Figure 20.1) | The Project landfall facilities will be connected to the upstream pipeline network which forms part of the Expansion of the UGS and includes the Russkaya CS. Some construction activities will occur at the same time as Project construction works. The Russkaya CS development thus interacts with the Project both spatially and temporally.

Given that the Russkaya CS and the four connecting pipelines have been defined as associated facilities, there is a need to consider the Russkaya CS development’s potential environmental and social implications given that such impacts will be additional to the impacts Project impacts (and as reported within the ESIA technical assessment chapters).

In addition to the discussion on cumulative impacts as presented herein, Appendix 20.1 provides details of the Russkaya CS environmental impacts as reported in the development EIA (Ref. 20.3 and Ref. 20.4). Thereafter the appendix presents an appraisal of potential combined impacts of the Russkaya CS plus the Project. This combined appraisal has a different focus to the CIA – namely the CIA focuses on the risks of concurrent Project and Russkaya CS (and other developments scoped into the CIA) activities generating cumulative impacts upon sensitive receptors (VECs) that are common to both developments, whereas the collective appraisal considers the potential impacts of the Project and the Russkaya CS development (as though this were one development) upon sensitive receptors (during construction and operational phases).

Rosneft Oil Exploration Licenses (see Figure 20.3) | As illustrated in Figure 20.3, the Project offshore pipelines pass through the Rosneft exploration blocks at Tuapse Trough and West Chernomorsky. As detailed in Section 20.6.2.3, specific details regarding Rosneft exploration proposals are not currently available. It is not possible to undertake a meaningful cumulative impact assessment due to a lack of available information. South Stream Transport will seek to further liaise with Rosneft with the aim of minimising the potential for any cumulative marine environmental impacts that might result from any simultaneous activities.

<tr>
<td>Anapolis development (see Figure 20.1 development D)</td>
<td>This proposed mixed use development covers an area of approximately 66.7 hectares and is located approximately 350 m south of the Pipeline alignment. The construction phase for this development may start within 2014. Given the location of the development, this development has been scoped into the CIA.</td>
<td>Scoped in</td>
</tr>
</tbody>
</table>
These proposed developments are at the conceptual planning stage and thus there is little information available regarding the development details (e.g. development footprints) and their associated construction programmes. It is, however, considered most likely that these areas would only be developed after completion of Project construction activities. Given the nature of these proposed developments, their degree of separation from the Project, and the conceptual nature of such proposals (meaning that there is a lack of information available to assess the potential for cumulative impacts), these development proposals have been scoped out of the CIA.
20.7 CIA and Significance Assessment

Section 20.5.3 defined the VECs and associated impact sources that need to be considered as part of the CIA, namely the following:

- Construction Phase impacts upon the prevailing landscape character and visually sensitive human receptors;
- Reduced residential amenity for residents in local communities, specifically north east Varvarovka, during the Construction and Pre-Commissioning Phase due to potential combined noise and visual impacts;
- Construction Phase impacts upon discrete marine cultural heritage resources; and
- Waste disposal of material at the Alfa Landfill.

Section 20.6.3 identified the developments that have the potential to interact with the Project (spatially and/or temporally) in a manner that could result in significant cumulative impacts (additive, interactive or spin-off impacts as per Section 20.2).

The sections below consider the potential for VECs to experience potential cumulative impacts, focusing in particular upon the VECs and associated impact sources highlighted in the bullet points above. In addition, the sections below also consider some VECs which experience a Not Significant or Low Adverse residual impact (as detailed in Table 20.2) where the potential for cumulative impacts warrants further consideration due to the sensitivity/importance of affected VECs. To assist with this process, the various development projects included in Section 20.6 have been considered, together with VEC residual impact levels as indicated in Table 20.2 and VEC location. Table 20.4 summarises the results from this analysis and indicates which developments have been considered by the various VEC-specific cumulative impact assessments.

The potential for cumulative traffic and transportation impacts has also been considered. Whilst traffic is not a defined VEC, traffic flow changes have the ability to impact upon VECs i.e. human receptors that are being considered within this CIA.

In the sections below, if a cumulative impact risk is identified, the significance of the potential cumulative impact is either quantified or qualified (depending upon data availability).

20.7.1 Soil, Groundwater and Surface Water

Chapter 8 Soil, Groundwater and Surface Water (summarised in Table 20.2) reports that the residual impacts upon soils, surface water and groundwater are predicted to be either Not Significant or Low Adverse during all Project phases, with impacts generally being local to the Project site and its immediate surrounds. This indicates that the Project's ability to contribute to a soils, surface water and groundwater cumulative impact with other potential developments scoped into the CIA is very limited.

20.7.1.1 Russkaya CS Development

The sections below consider the potential for cumulative soils, surface water and groundwater impacts of the Project and the Russkaya CS (and associated pipelines) as this represents the scenario with the greatest risk of generating a potential cumulative impact upon these resources:

- **Soils:** A number of Low Adverse impacts have been identified during the Construction and Pre-Commissioning Phases on Agricultural, Fluvisol and Phaeozem soils (due to activities such as the storage and use of potentially polluting materials; vegetation clearance which increases soil susceptibility to erosion; earth moving activities increasing the risk of slope failures / soil movement / subsidence / slope erosion and soil compaction); loss of soil by excavations) (Chapter 8 Soil, Groundwater and Surface Water).

  The Russkaya CS construction activities have the potential to impact upon the same soil types as those impacted by the Project. The Russkaya CS EIA Report (Ref. 20.3 and Ref. 20.4) highlights that a range of mitigation measures will be applied to reduce impacts upon soil resources. Whilst the Russkaya CS development and the Project both have the potential to impact upon soil resources, both will adopt a range of mitigation measures to limit the impacts associated with land clearance and earthworks, accidental leakages and spillages. In addition, the areas collectively impacted are also spatially limited to the development footprints, which are small when compared to the regional soil resource. On this basis, no significant cumulative impacts on area soil resources are anticipated with respect to the concurrent development of the Russkaya CS and the Project.

  No significant cumulative impacts on soils are anticipated during the Operational Phase given that all Project impacts are predicted to be Not Significant;

- **Groundwater:** the assessment presented in Chapter 8 Soil, Groundwater and Surface Water indicates a Low Adverse residual impact upon the superficial aquifer and carbonate aquifer both during the Construction and Pre-Commissioning Phase and the Operational Phase. Impacts potentially arise due to the storage and use of potentially polluting materials; leaks of seawater from the Pipeline to groundwater during hydro-testing and groundwater quality impacts during microtunnelling.

  The Russkaya CS development is located over the same aquifer system as the Project. With the exception of using water supply wells, the construction activities for the Russkaya CS development are similar to the Project. The Russkaya CS EIA Report (Ref. 20.3 and Ref. 20.4) highlights that a range of mitigation measures will be applied to reduce impacts upon groundwater resources.
Whilst the Russkaya CS and the Project both have the potential to impact upon the area’s groundwater resources, they will adopt a range of mitigation measures to limit the impacts associated with wastewater management and disposal, stormwater management and the disposal and accidental leakages and spillages. The area that could be collectively impacted is small relative to the entire carbonate aquifer. On this basis, no significant cumulative impacts on the area’s groundwater resource are anticipated. Given the distance of over 5 km between the Project and the Russkaya CS water supply wells, a cumulative impact upon groundwater resources is not anticipated during the Project Operational Phase; and

- **Surface Waters**: the assessment presented in Chapter 8 Soil, Groundwater and Surface Water indicates Not Significant / Low Adverse residual impacts upon a number of surface water features, namely the Shingar River, a tributary in the Graphova Gap, and an existing surface water abstraction during both the Construction and Pre-Commissioning Phase and the Operational Phase.

The Russkaya CS development pipeline section is partly located within the same surface water catchment (the tributary in the Graphova Gap) as the majority of the Project. The construction activities for the Russkaya CS development are similar to the Project. The Russkaya CS development has the potential to impact upon surface waters in the Project Area only during periods when the watercourses are flowing and may impact upon the downstream stretches of the tributary in the Graphova Gap. The Russkaya CS EIA Report (Ref. 20.3 and Ref. 20.4) highlights that a range of mitigation measures will be applied to reduce impacts upon surface water resources.

The Russkaya CS and the Project will both adopt a range of mitigation measures to limit the impacts associated with activities such as land clearance, earthworks, open-cut river crossings, wastewater management and disposal, storm water management and disposal and accidental leakages and spillages.

Overall it is considered that there is a potential for low significance cumulative impacts on surface water resources. However, any such impacts would be temporary due to the ephemeral nature of the watercourses in the catchment and the temporary duration of development activities.

Significant cumulative impacts upon surface water during the Operational Phase are not anticipated given that the Russkaya CS and the Project will both adopt a range of mitigation measures to limit the impacts associated with the presence of the technical facilities and access roads, accidental leakages and spillages, and on-going vegetation control along the RoWs of the respective pipelines.

### 20.7.1.2 Lesnaya Polyana, Club Village Chateau and Anapolis Developments

The potential for cumulative soils, surface water and groundwater impacts as associated with the Lesnaya Polyana, Club Village Chateau and Anapolis developments are considered in the sections below:

- **Lesnaya Polyana**: given the nature and scale of the development (16.5 ha), its location on highly modified land on the outskirts of Varvarovka, and given that it is understood that site levelling has already been carried out, cumulative soil, surface water and groundwater
impacts are not anticipated during the Project Construction Phase. This is particularly the case if the development construction works are completed prior to Project development.

During the Project Operational Phase, the Lesnaya Polyana development is not anticipated to generate any cumulative soil, surface water and groundwater impacts given the residential nature of the development (without any significant soil, surface water and groundwater impact sources). Whilst the source of water supply to the development is uncertain, it is assumed that the use of any water supply wells will be undertaken in compliance with local regulatory authority requirements in a manner that does not adversely impact upon groundwater resources;

- **Club Village Chateau:** soil, surface water and groundwater impacts during the Project Construction Phase would be avoided given that it is understood that the Club Village Chateau development will be delayed until after completion of Project construction activities (given that the road which passes through the development plot will be used as a Project access road).

During the Project Operational Phase, construction and then use of the Club Village Chateau development is not anticipated to generate any cumulative soil, surface water and groundwater impacts given the disturbed nature of the site and the semi-rural residential nature of the development (without any significant soil, surface water and groundwater impact sources). Whilst the source of water supply to the development is uncertain, it is assumed that the use of any water supply wells will be undertaken in compliance with local regulatory authority requirements in a manner that does not adversely impact upon groundwater resources; and

- **Anapolis Development:** it is currently uncertain if this Anapolis development’s construction phase will coincide with the Project Construction Phase. If such works were to coincide, it is considered that given the nature of the Anapolis development, and given the mitigation measures to be employed by the Project, that significant cumulative soil, surface water and groundwater impacts will be avoided.

During the Project Operational phase, use of the Anapolis development is not anticipated to generate any cumulative soil, surface water and groundwater impacts given the mixed use residential nature of the development (without any significant soil, surface water and groundwater impact sources). Whilst the source of water supply to the development is uncertain, it is assumed that the use of any water supply wells will be undertaken in compliance with local regulatory authority requirements in a manner that does not adversely impact upon groundwater resources.

### 20.7.2 Air Quality

**Chapter 9 Air Quality** (as summarised in Table 20.2) reports that the residual air quality impacts upon human and ecological VECs are all predicted to be either Not Significant or Low Adverse during all Project phases. This indicates that the Project has limited potential to contribute to an air quality cumulative impact when considering the other developments scoped into the CIA. Nevertheless, the sections below discuss potential cumulative air quality issues during the Construction and Pre-Commissioning Phase taking into account the construction of
the Russkaya CS development as well as construction of other potential developments in the vicinity of the Project (see Table 20.4).

20.7.2.1 Russkaya CS Development

Construction and Pre-Commissioning Phase

The sections below consider the potential for dust and nitrogen dioxide related cumulative impacts from concurrent construction of the Russkaya CS and the Project.

The EIA for the Russkaya CS (Ref. 20.3 and 20.4) does not quantify dust emissions from construction equipment and vehicles. However, most dust including the finer particulates, is anticipated to be deposited within approximately 1 km of an emission source – as such, dust from the Russkaya CS construction works are unlikely to affect Gai Kodzor, which is the nearest populated area (located approximately 1.6 km north of the Russkaya CS construction site). Given that the Project would not result in any dust related impacts upon Gai Kodzor a dust related cumulative impact would be avoided at these residential receptors. Similarly, no other VECs are anticipated to experience a dust related cumulative impact.

The greatest air quality impact from the construction of the Russkaya CS and associated pipeline is on nitrogen dioxide (NO₂) concentrations. The Russkaya CS EIA (Ref. 20.3 and 20.4) has assessed the impact of its construction phase activities on 20 minute Maximum Permissible Concentration (MPC) nitrogen dioxide concentrations. Concentrations are predicted to increase at Gai Kodzor from the current level, which is approximately 25% of the national regulatory limit, to 33% of the regulatory limit.

The receptors most likely to be affected by potential cumulative construction impacts associated with the Russkaya CS and the Project are as follows (refer to Figure 9.4 in Chapter 9 Air Quality for receptor locations):

- Receptor 5 (Lesnaya Polyana) – Most affected by the Project Construction Phase. The southern boundary of a proposed residential development currently under construction lies approximately 500 m northwest of the microtunnel entry points and 1.5 km southwest of the landfall facilities; and
- Receptor 10 (Gai Kodzor) – Most affected by the construction of the Russkaya CS. The southern edge of the nearby town Gai Kodzor lies approximately 4.5 km northeast of the landfall facilities.

The construction of the Russkaya CS pipeline from the compressor station to the landfall facilities could occur simultaneously with the laying of the Project Pipeline. If the works were to occur simultaneously, the theoretical combined impact of the two construction operations is provided in Table 20.5.
Table 20.5 Assessment of Potential Cumulative Construction Impacts on MPC NO₂ Concentrations

<table>
<thead>
<tr>
<th>Receptor</th>
<th>South Stream Construction Impact (% MPC)</th>
<th>Russkaya CS Construction Impact (% MPC)</th>
<th>Combined Impact (% MPC)</th>
<th>Impact Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receptor 5</td>
<td>65</td>
<td>2</td>
<td>67</td>
<td>Low Significance</td>
</tr>
<tr>
<td>Receptor 10</td>
<td>28</td>
<td>8</td>
<td>36</td>
<td>Not Significant</td>
</tr>
</tbody>
</table>

Table 20.5 illustrates that the national (and Project Standard) requirement that concentrations should not exceed 0.8 of the MPC would be satisfied at both receptors (see Chapter 9 Air Quality for more details). Taking background concentrations into account, the total MPC concentration would be 71% of the MPC at Receptor 5 and therefore below the national requirement.

As described in Chapter 9 Air Quality, an impact of the magnitude predicted at Varvarovka (Receptor 5) is more than 50% of the short term standard of 200 µg/m³ and as such is categorised as a high magnitude impact. As this impact would occur in an area containing receptors of ‘negligible’ sensitivity (residential properties outside of urban centres), it can be regarded as an impact of Low Adverse significance (with the Russkaya CS construction works making an insignificant contribution to this impact). At Gai Kodzor, the impact is less than 50% of the short term limit. This is categorised as a moderate magnitude impact (on a low sensitivity receptor), and can be regarded as being Not Significant.

The analysis above indicates that concurrent construction of the Russkaya CS and the Project would not result in a significant cumulative nitrogen dioxide MPC impact. Furthermore this cumulative assessment is based on unfavourable meteorological conditions, and thus the analysis represents an improbable very worst case. Similarly, receptors located further from the two developments are not predicted to experience a cumulative nitrogen dioxide impact during the Construction and Pre-Commissioning Phase.

### 20.7.2.2 Lesnaya Polyana and Anapolis Developments

The Lesnaya Polyana and the Anapolis developments have the potential to generate airborne dust, emit atmospheric emissions associated with the site plant, and generate additional truck movements if they are constructed at the same time as the Project construction activities. However, these impacts are likely to be localised and short-term in nature. Dust and site plant emissions are likely to only be an issue in the immediate vicinity of these sites (with the majority of the construction generated dust depositing within 100 m), and hence should not contribute to a cumulative air quality impact when considered with the Project.

For the Lesnaya Polyana development, construction is already underway and, despite being unlikely, could be complete and fully occupied in advance of construction starting on the Project. This would essentially eliminate the potential for air quality related cumulative impacts.
Recognising it might be completed and occupied, the Lesnaya Polyana development has already been considered as a sensitive receptor in the air quality impact assessment (Receptor 5), which concluded that this receptor would experience a **Not Significant** dust impact during the Construction Phase of the Project. Given the dust generated by the Lesnaya Polyana and Anapolis developments is expected to be localised and that the Project’s impact on Lesnaya Polyana has been assessed as **Not Significant**, the cumulative impacts associated with construction dust and site plant emissions are therefore also expected to remain **Not Significant**.

The effect on air quality from traffic generation associated with these residential schemes during their construction is expected to be relatively minor, as such traffic is likely to be well distributed across the regional road network. The assessment of road traffic emissions for the Project showed that construction road traffic contributes relatively little to pollutant concentrations along the two key transport routes for the Project, and that the Project would have a negligible magnitude impact upon air quality. On the basis that the marginal increase in traffic flow along these routes is not expected to result in a discernible increase in the pollutant levels, the cumulative impact for air quality is expected to remain **Not Significant**.

### 20.7.2.3 Club Village Chateau

Whilst the Club Village Chateau development has the potential to generate airborne dust and emit atmospheric emissions as associated with the site plant, and generate additional truck movements, this development will not take place until after completion of Project construction activities. As such, cumulative construction air quality impacts would be avoided.

### 20.7.3 Noise and Vibration

An assessment of the worst case noise and vibration impacts associated with Project construction has been undertaken which indicates that noise and vibration impacts will generally be **Not Significant** at all existing sensitive receptors neighbouring the Project. As such the Project has limited potential to contribute to a cumulative noise and vibration impact in combination with the other developments scoped into the CIA.

Whilst it is considered that the Project has a very limited potential to contribute to cumulative noise and vibration impacts with the Russkaya CS (due to residual impact magnitudes largely being of negligible magnitude), the sections below test this hypothesis by considering the potential cumulative noise impacts of the Project and the Russkaya CS (and associated pipelines) assuming that both construction programmes occur simultaneously. This represents the scenario with the greatest risk of generating a potential cumulative noise and vibration impact.

The closest noise sensitive residential receptors, and hence the receptors likely to be affected by worst case noise levels generated by concurrent Project and Russkaya CS construction activities, are as follows (refer to Figure 10.2 in Chapter 10 for receptor locations):

- **Receptor 3** - A residential dwelling situated in the north-eastern part of Varvarovka, approximately 1.4 km north of the landfall facilities;
- Receptor 4 - A residential dwelling situated in the north-eastern part of Varvarovka, approximately 1.5 km north of the landfall facilities; and
- Receptor 8 - Two log cabins that have recently been built on cleared land, approximately 1.3 km south of the landfall facilities.

The construction of the Russkaya CS pipeline from the compressor station to the landfall facilities could occur simultaneously with the laying of the Project Pipeline. An assessment of the worst case construction noise impacts is summarised in Table 20.6, taking the highest predicted construction noise at identified receptor locations.

**Table 20.6 Assessment of Cumulative Construction Impacts**

<table>
<thead>
<tr>
<th>Receptor</th>
<th>South Stream Construction Noise Level (dB(A))</th>
<th>Russkaya CS Construction Noise Level (dB(A))</th>
<th>Worst Case Cumulative Noise Level (dB(A))</th>
<th>Russian Noise Limit (dB(A))</th>
<th>Impact Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Receptor 3</td>
<td>40</td>
<td>19</td>
<td>40</td>
<td>55</td>
<td>Not Significant</td>
</tr>
<tr>
<td>Receptor 4</td>
<td>50</td>
<td>21</td>
<td>50</td>
<td>55</td>
<td>Low Adverse</td>
</tr>
<tr>
<td>Receptor 8</td>
<td>40</td>
<td>22</td>
<td>40</td>
<td>55</td>
<td>Not Significant</td>
</tr>
</tbody>
</table>

Table 20.6 indicates that the noise generated by concurrent construction of the Project and the Russkaya CS will have an impact of **Low Adverse** significance at the most exposed receptor (Receptor 4). However, the predicted noise level and therefore impact significance is the same as for the Project only scenario as detailed in Chapter 10 Noise and Vibration and thus the Russkaya CS construction works are not causing an additional noise impact at Receptor 4. At receptors 3 and 8, the significance of the noise impact is **Not Significant**. As the daytime noise limit of 55 dB(A) as given in the Russian Federation regulations (and IFC4) will not be exceeded at any of these receptors, it is considered that all these noise impacts are acceptable.

The analysis above indicates that concurrent construction of the Project and the Russkaya CS facilities will not result in a significant cumulative noise impact at locations exposed to both developments.

### 20.7.4 Terrestrial Ecology

Section 20.5.3 indicated that residual terrestrial ecological impacts associated with Project induced habitat loss will be **Not Significant** or of **Low Adverse** significance, which indicates that the Project's ability to contribute to a cumulative terrestrial ecological impact, when considering the other developments scoped into the CIA, is very limited and can thus be scoped.

---

4 The Russian Regulations provide a more stringent approach to the limiting of noise than that given in the IFC General EHS Guidelines as there is no allowance for elevated noise levels where the prevailing ambient noise climate is already over the prescribed noise limit – refer to Chapter 10 Noise and Vibration.
out of the CIA. However, given the ecological sensitivity of the area in the vicinity of the Project, the sections below consider the potential for cumulative ecological impacts as a result of the other development scoped into the CIA (see Table 20.4).

20.7.4.1 Russkaya Compressor Station (CS)

The Russkaya CS development (Ref. 20.3 and Ref. 20.4) comprises three components of interest to this cumulative impact assessment: the compressor station, the four pipelines (referred to hereafter as the Russkaya CS Right of Way (RoW) running from the compressor station to the Project’s landfall facility, and a permanent access road which runs from near the town of Varvarovka, eastward across the Graphova Gap, past the Project’s landfall facilities to the safety valve station of the Russkaya CS development (the ‘Gazprom Invest permanent access road’ - see Chapter 5 Project Description for the location of this permanent access road).

The Russkaya CS EIA Report (Ref. 20.3 and Ref. 20.4) has been reviewed in order to determine if significant cumulative effects between the Project and Russkaya CS are likely. The report presents the terrestrial ecology baseline for the Russkaya CS development and presents an assessment of the likely effect of the development on terrestrial ecology receptors.

To supplement the information contained within the Russkaya CS EIA, a walkover survey of the Russkaya CS RoW was undertaken in June 2013 in conjunction with ecology surveys for the Project (see Section 11.4.4.1). That walkover survey mapped vegetation to a distance of 100 m either side of the Russkaya CS RoW centreline and recorded incidental sightings of Red Data Book (RDB) species.

The paragraphs below present a receptor-based assessment of the potential for significant cumulative impacts resulting from combined impacts of the Russkaya CS and the Project. This assessment is based on this ESIA for the Project, on the information described in the Russkaya CS EIA, and on the June 2013 walkover survey data.

Habitats and Flora

Surveys for the Russkaya CS EIA recorded woodland, meadow, and anthropogenic habitats (including agricultural land). The 2013 walkover survey classified these habitats and recorded their extent and distribution within 100 m of the Russkaya CS RoW centreline. Habitats recorded included shiblyak, mesophilic forest, juniper woodland, secondary steppefied meadow, mesophilic meadow, and agricultural habitats.

The Russkaya CS EIA reports that the impact of construction of the Russkaya CS on these habitats will directly (through habitat loss) and indirectly (degradation) affect areas of both natural and modified habitats, including large swathes of woodland (predominantly shiblyak) habitat. The area of habitat loss is not, however, quantified within the Russkaya CS EIA.

For the purpose of this CIA, and to provide an indication of the area likely to be directly affected by the Russkaya CS RoW, a 120 m wide construction corridor has been assumed which equates to a construction area of approximately 38.7 ha. Based on available information, the footprint of the compressor station is approximately 52 ha, whilst the construction footprint for the Gazprom Invest permanent access road is estimated to be approximately 4.5 ha and an area of approximately 16.1 ha will be required as a temporary construction works area. The total
construction footprint of the Russkaya CS development is thus assessed to be approximately 111.3 ha (see Section 20.6.2.2).

Table 20.7 presents a comparison of the direct habitat loss occurring as a result of the Project compared to that as a result of the Russkaya CS RoW. The habitat type for the footprint of the compressor station is given as “unknown” because this is not described in the Russkaya CS EIA, and the South Stream Transport 2013 survey was unable to survey the compressor station footprint as construction had already started; however, satellite imagery suggests that the dominant habitat types may have been agricultural, meadow, and forest.

The Russkaya CS EIA proposes control measures to avoid impacts to habitats, and proposes mitigation measures aimed at replacing lost habitat; measures are described to avoid pollution and degradation to habitats, and habitat creation and compensatory planting measures (where possible). It is not, however, clear within the Russkaya CS EIA whether the mitigation measures proposed will reduce residual impacts on ecological receptors to not significant levels.

Construction of both the Russkaya CS and the Project will result in the loss of ecologically valuable habitats (see Table 20.7). The residual impact for habitat loss for the Project are anticipated to be Not Significant due to the provision of mitigation measures to safeguard habitats during construction, and where significant impacts occur, to implement habitat reinstatement and creation. This includes provision for a Biodiversity Action Plan (BAP) which will aim to achieve no net loss of biodiversity, and in the case of a component of Critical Habitat (such as mesophilic forest), a net gain.

Accordingly, the Project is not anticipated to significantly contribute to cumulative impacts with the Russkaya CS. There is, however, an opportunity to enhance the benefits to biodiversity management if the Project’s mitigation measures were extended to encompass the wider area. South Stream Transport will therefore seek to engage with Gazprom Invest with an aim to align
Gazprom Invest's mitigation measures with those of the Project, where practicable. Furthermore, in developing their BAP, South Stream Transport will seek to engage with Gazprom Invest with an aim to develop measures that would enhance biodiversity management within the wider area.

Fauna

The Russkaya CS EIA recognises that habitat loss and degradation have the potential to adversely affect terrestrial fauna, including herpetiles (such as the RDB species Nikolski's tortoise), mammals (including bats), and birds (including breeding and migratory species). The Russkaya CS EIA does not, however, quantify this loss or ascribe a clear significance to this loss.

The walkover survey of the Russkaya CS RoW conducted by South Stream Transport in 2013 identified very similar habitat types to those recorded within the Landfall Study Area (although, generally speaking, of a greater extent - see Table 20.7). It is therefore likely that the assemblage of species supported by habitats within the Russkaya CS zone of influence is similar to that of the Landfall Study Area, although potentially supporting larger populations considering the larger size of the Russkaya CS footprint.

Based on information contained within the Russkaya CS EIA, and supplementary information gathered by South Stream Transport, predicted impacts of the Russkaya CS development on fauna include the following:

- Direct loss and indirect degradation to habitats (foraging, sheltering, breeding, and hibernation);
- Habitat fragmentation and severance; and
- Potential mortality, injury and disturbance to species supported within these habitats.

These issues are discussed in turn below.

Direct Loss and Indirect Degradation to Habitats

The Russkaya CS EIA proposes measures to avoid and mitigate for habitat loss and degradation - this includes measures for habitat reinstatement and creation, where appropriate. The Russkaya CS EIA also argues that, following construction, additional beneficial effects for some species will be realised (including herpetiles, birds, mammals, and invertebrates), as meadow habitat develops along the previously forested Russkaya CS RoW. Although not clearly reported within the Russkaya CS EIA, it is implied that the long term effect of the loss of habitat for fauna is anticipated to be not significant.

As discussed in Chapter 11 Terrestrial Ecology, the Project is not anticipated to significantly reduce the extent or diversity of suitable habitat in the long term, due to the implementation of mitigation measures (including provision of a BAP).

Habitat Fragmentation and Severance

Construction of the Project and the Russkaya CS development, which are anticipated to occur simultaneously, both have the potential to fragment habitat and restrict the movement of
species within the local environment. Habitat fragmentation and severance is likely to occur due to the following elements of both projects:

- Project: Construction of the eastern-most access road, running north-south;
- Project: Construction of the western-most microtunnel access road, running north-south;
- Project: The South Stream Transport RoW and landfall facilities, running generally east-west;
- Russkaya CS: The permanent access road running east-west; and
- Russkaya CS: The Russkaya CS RoW and compressor station, running generally east-west.

Construction of the RoWs of both projects will result in a relatively temporary obstruction (1 – 2 years) to faunal movement. Once construction is completed, the RoWs are not anticipated to limit the movement of species within the landscape. However, the access roads, if permanent, have the potential to disrupt the movement of species (as well as cause mortality due to collisions) in the long term. The species groups that are likely to be affected by habitat fragmentation and severance include herpetiles and non-flying, small mammal species.

Measures to safeguard species from collision-based mortality during construction have been proposed for the Project in this ESIA Report (Chapter 11 Terrestrial Ecology). This includes the erection of herpetile and small mammal-proof fencing, which is designed to exclude these species from the construction areas and access roads. Furthermore, it is proposed that the Project install a number of under-road tunnels with the purpose of allowing herpetiles to pass beneath the roads once constructed. Tunnels will be placed at appropriate locations to ensure that there are a sufficient number to mitigate the severance effect.

Measures to reduce the effect of severance (both short- and long-term) and habitat fragmentation are not proposed in the Russkaya CS EIA Report. Although it is not anticipated that the Project’s contribution to the cumulative impact of severance will be significant, there is nonetheless the potential for habitat severance within the wider environment to be exacerbated if the Russkaya CS development does not implement appropriate mitigation.

As discussed above, South Stream Transport will engage with Gazprom Invest with an aim to align Gazprom Invest’s mitigation measures with those of the Project, where practicable.

**Direct Mortality, Injury and Disturbance**

There is the potential for both the Project and Russkaya CS to cause direct mortality, injury or disturbance of fauna during construction, including RDB species.

The Russkaya CS EIA proposes measures to avoid impacts on fauna, including control measures to avoid environmental pollution and fires, restrict the extent of construction to only necessary areas, and avoidance of vegetation clearance during sensitive periods; with respect to the latter, the bird breeding season is addressed, although no mention is made of the herpetile hibernation period. In addition, the following measures are proposed in the Russkaya CS EIA Report specifically for RDB species:

- Restriction of spring burns of grass vegetation which might lead to the death of animals;
• Banning of chasing animals, destroying nests and shelters, and illegal shooting;
• Banning keeping tame animals in residential settlements, control on keeping guard dogs on the construction sites; and
• Minimising disturbance in areas adjacent to the construction site.

It is not clear in the Russkaya CS EIA Report whether the proposed mitigation measures will reduce residual impacts of mortality, injury and disturbance on ecological receptors to non-significant levels.

For the purpose of this CIA, an attempt has been made to estimate the number of Nikolski’s tortoise with the potential to be directly impacted during construction phases of both projects; this has not been undertaken within the Russkaya CS EIA. This estimate has been based on density figures for the tortoise within the Abrau peninsula, derived from a recent publication (Ref. 20.12). The combined area which is likely to be directly affected by both developments and the extrapolated density value are presented in Table 20.8. It is important to note that these figures are based on the density of tortoises within each habitat type during the species’ activity period (approximately April – November) and do not reflect species density during hibernation.

This estimate, based on the area of habitat to be directly impacted, should be viewed as the minimum number of tortoises which could potentially be affected by both developments. This does not take into account the range of indirect impacts (disturbance during breeding/hibernation, habitat severance and associated reduced access to resources etc.) which have the potential to affect the wider local tortoise population supported by habitats outside of the development’s construction footprint. The number of tortoises affected could, therefore, be significantly higher than the 80 – 188 which have the potential to experience direct effects.

---

5 Includes both temporary and permanent habitat loss.
Chapter 20 Cumulative Impact Assessment

Assuming that the published density figures are applicable to the combined project construction areas, Table 20.8 indicates that removal of various habitat types has the potential to directly affect (through mortality, injury, or direct loss of habitat) 80 - 188 tortoises (noting that the contribution of the Project equates to approximately 19% of the lower range (or 15 of the 80 tortoises) and approximately 13% of the upper range (or 24 of the 188 tortoises). Combined direct habitat losses could thus impact upon approximately 1.1% - 2.7% of the Abrau peninsula’s Nikolski’s tortoise population (Ref. 20.11), a significant proportion of the regional Nikolski’s tortoise population.

The Project will implement various measures to safeguard this species during the Construction Phase (including design controls, appointment of an Ecological Clerk of Works (ECoW), sensitive timing of works, as well as fencing and a programme of capture and placement). These measures, in conjunction with implementation of a BAP, are anticipated to reduce the residual impact of potential Project-related mortality, to **Not Significant** levels. The contribution of the Project to potential cumulative impacts upon herpetiles is, therefore, considered to be **Not Significant**.

Nonetheless, as discussed above, South Stream Transport will engage with Gazprom Invest with an aim to align Gazprom Invest’s mitigation measures with those of the Project, where practicable. Of particular importance should be the avoidance of impacts through the sensitive timings of works (including the herpetiles hibernation period), implementation of herpetile fencing and a programme of translocation, and adherence to Good International Industry Practice (GIIP) (see Section **Chapter 11 Terrestrial Ecology**).

### 20.7.4.2 Lesnaya Polyana

The Lesnaya Polyana development is located approximately 500 m to the north of the Project. The site is located within an area that consists of predominantly agricultural land. It is, however, adjacent to an area of what is likely to be shiblyak woodland. Given the limited extent of the proposed development, and its siting on an area of (predominantly) previously developed land, it is not anticipated that this development would result in a significant ecological impact in combination with the Project.

### 20.7.4.3 The Anapolis Development

The Anapolis mixed use development covers an area of approximately 65 hectares and is located approximately 350 m south of the Project’s microtunnel entry shafts. The construction phase for this development is currently uncertain and no EIA is currently available for review. The cumulative impact assessment has, therefore, been undertaken based on available information regarding the location and extent of the Anapolis development and, as a large proportion of Anapolis falls within the Landfall Study Area, information gathered for the ESIA.

*Habitats, Flora and Fauna*

Based on information gathered for the ESIA, data on the habitats contained within Anapolis’ development footprint is presented within Table 20.9. For illustrative purposes, the area of habitat loss for the Project and Russkaya CS are also presented.

</tr>
</tbody>
</table>

Information is not available at present on what proportion of the habitats contained within the Anapolis development footprint would be subject to direct loss. There is, however, the potential for the development to result in the direct loss and indirect degradation of relatively large areas of natural habitat.

As a large proportion of Anapolis is located within the Landfall Study Area, it is likely that populations of species which have been recorded during surveys for the Project, including herpetiles, birds, mammals, and invertebrates, will use and be supported by the habitats contained within the Anapolis footprint.

In terms of potential cumulative impacts to fauna, the following impacts are considered key to the CIA:

- Direct loss and indirect degradation to habitats (including foraging, sheltering, breeding, and hibernation habitat for species); and
- Potential mortality, injury and disturbance to species supported within these habitats.

Anapolis is not anticipated to contribute to or exacerbate the impact of habitat fragmentation or severance in combination with the Project.

Cumulative habitat loss within the wider environment is acknowledged as a potentially significant adverse impact if appropriate measures are not taken to mitigate for this loss. The
residual impacts for the Project are anticipated to be **Not Significant**, due to the provision of mitigation measures (including a BAP) which will aim to achieve no net loss of biodiversity and a net gain in Critical Habitat. Accordingly, the Project is not anticipated to make a significant contribution to cumulative impacts with Anapolis or any other cumulative scheme.

However, where there is opportunity to do so, the benefits for biodiversity due to the Project’s mitigation measures (e.g. BAP) will be extended to encompass the wider area. South Stream Transport will engage with the Anapolis developers (Fund Yug) with the aim of aligning Anapolis’ mitigation measures with those of the Project, developing measures that would enhance biodiversity management within the wider area.

**20.7.4.4 Club Village Chateau**

As detailed in Section 20.6.2.8, the Club Village Chateau development (see Figure 20.1) involves the development of approximately 45 chateaus within an area of existing vineyards. The development plot covers a total area of approximately 83 ha, although the construction works are estimated to impact upon approximately 20% of the total development footprint (calculated from a review of the proposed development) thus an area of approximately 16.6 ha. It is understood that the development will only proceed following completion of the Project Construction Phase given that the road which passes through the development plot will be used as a Project access road. The Club Village Chateau development is located approximately 250 m and 1,500 m, at its nearest and furthest point, respectively, northwest of the Project’s RoW and landfall facilities.

**Habitats and Flora**

Based on available information, it is estimated that construction activities are likely to directly affect approximately 16.6 ha of the development site occupied by vineyard / meadow habitat and shiblyak woodland. Based on information gathered for the ESIA, data on the habitats contained within Club Village Chateau development footprint is presented within Table 20.10. For illustrative purposes, the area of habitat loss for the Project, the Russkaya CS and the Club Village Chateau development are presented.

Cumulative habitat loss within the wider environment is acknowledged as a potentially adverse impact if appropriate measures are not taken to mitigate for such losses. The residual impacts of the Project are anticipated to be **Not Significant**, due to the provision of mitigation measures (including a BAP) which will aim to achieve no net loss of biodiversity and a net gain in Critical Habitat. Accordingly, the Project is not anticipated to make a significant contribution to cumulative impacts with the Club Village Chateau development or any other cumulative scheme.

Nevertheless, South Stream Transport will engage with the developers of the Club Village Chateau development (Fund Yug) with the aim of aligning their mitigation measures with those of the Project, where practicable.

**Fauna**

As a large proportion of the Club Village Chateau development is contiguous with the Project’s Study Area, it is likely that populations of species which have been recorded during surveys for the Project, including herpetofauna, birds, mammals, and invertebrates, will use and be supported by the habitats contained within the Club Chateau Village development footprint.

In terms of potential cumulative impacts to fauna, the following impacts are considered key to the cumulative impact assessment:

- Direct loss and indirect degradation to habitats (including foraging, sheltering, breeding, and hibernation habitat for species);
- Potential mortality, injury and disturbance to species supported within these habitats; and
- Habitat fragmentation and severance.

The Project will implement various measures to safeguard species during the Construction Phase (including design controls, appointment of an Ecological Clerk of Works (ECoW), sensitive timing of works, as well as fencing and a programme of capture and placement). These measures, in conjunction with implementation of a BAP are anticipated to reduce the residual cumulative impacts.
impact of potential Project-related mortality, to **Not Significant** levels. The contribution of the Project to cumulative impacts is, therefore, considered to be **Not Significant**.

Although it is not anticipated that the Project’s contribution to the cumulative impact of severance will be significant, there is nonetheless the potential for habitat severance within the wider environment to be exacerbated if the Club Village Chateau development does not implement appropriate mitigation. As discussed above, South Stream Transport will engage with the developers of the Club Village Chateau development (Fund Yug) with an aim to align their mitigation measures with those of the Project and develop measures to enhance biodiversity management within the wider area where practicable.

### 20.7.4.5 All Developments

The sections above consider the potential for cumulative ecological impacts to be generated taking account of the various developments scoped into the CIA. However, Table 20.11 considers potential cumulative habitat losses should the Project, the Russkaya CS, Anapolis and the Club Village Chateau developments all be constructed.

**Table 20.11 Comparative Direct Habitat Loss of the Project, Russkaya CS, Anapolis and the Club Village Chateau Developments**

</tbody>
</table>

Table 20.11 indicates that Project, the Russkaya CS, Anapolis and the Club Village Chateau developments could result in the direct cumulative loss of approximately 257.9 ha habitat loss (of which approximately 25% is associated with the Project).

Such cumulative habitat loss within the wider environment is acknowledged as a potentially significant adverse impact if appropriate measures are not taken to mitigate for this loss. The
residual impacts for the Project are anticipated to be \textbf{Not Significant}, due to the provision of mitigation measures (including a BAP) which will aim to achieve no net loss of biodiversity and a net gain in Critical Habitat. Accordingly, the Project is not anticipated to make a significant contribution to the cumulative impacts due to habitat losses as associated with these collective developments.

As discussed above, South Stream Transport will engage with the developers of the Anapolis and the Club Village Chateau developments (Fund Yug) and with Gazprom Invest with an aim to align their mitigation measures with those of the Project and develop measures to enhance biodiversity management within the wider area, where practicable.

\textbf{20.7.5 Marine Ecology}

\textit{Chapter 12 Marine Ecology} (as summarised in Table 20.2) reports that residual marine ecology impacts are predicted to be \textbf{Low Adverse}.

As illustrated in Section 20.6.3, none of the developments scoped into the CIA involve significant marine construction activities (see Table 20.4) (noting that the Russkaya CS development will involve the use of marine vessels for materials supply, whereas impacts upon ecological receptors (such as noise) are most likely to be associated with pipe-laying and trenching activities rather than marine vessel passage). As such, it is considered that none of these developments has the potential to generate any potentially significant cumulative marine ecological impacts.

As noted in Table 20.3, with regard to potential Rosneft oil and gas exploration activities, South Stream Transport will seek to further liaise with Rosneft with the aim of minimising the potential for cumulative marine environmental impacts that might result from any simultaneous activities.

\textbf{20.7.6 Landscape and Visual Impacts}

\textit{Chapter 13 Landscape and Visual} (as summarized in Table 20.2) indicates that during the Construction and Pre-Commissioning Phase the Undulating Plateau landscape character area (LCA) would be subject to a temporary \textbf{Moderate Adverse} impact. However, such impact would be short term and will be \textbf{Not Significant} during the Operational Phase. With regard to visual impacts, during the Construction and Pre-Commissioning Phase the majority of residual visual impacts are identified to be either \textbf{Not Significant} or \textbf{Low Adverse}. However, a number of \textbf{Moderate Adverse} residual visual impacts have been identified in respect of the following receptors (principally due to the visual intrusion of construction activities and equipment):

- Recreational visitors to the seashore;
- Walkers on the coastal path along the cliff top;
- Visitors to the Russian Orthodox and Armenian cemetery at Varvarovka;
- Residents living at north east Varvarovka; and
- Recreational boat users.

These impacts are mostly direct, temporary and short-term. Visual impacts during the Operational Phase would be either \textbf{Not Significant} or \textbf{Low Adverse}.
Chapter 20 Cumulative Impact Assessment

The sections below consider the cumulative impacts upon landscape character and visual receptors resulting from the Project in combination with the various developments scoped into the CIA during the Construction and Pre-Commissioning Phase only (as potential Operational Phase cumulative impacts are considered to be Not Significant) (see Table 20.4).

20.7.6.1 Undulating Plateau Landscape Character Area

Construction and Pre-Commissioning Phase site clearance and construction works for the Project are assessed to result in a temporary Moderate Adverse residual impact upon the Undulating Plateau LCA. Additional landscape and visual impacts will also result from some of the developments scoped into the CIA that will be under development within the Undulating Plateau LCA at the same time as Project construction activities – e.g. construction works associated with the Russkaya CS, the Lesnaya Polyana development, the Club Village Chateau and the Anapolis development (the assessment also considers as applicable land developments such as those at Utrish, the Zapovedny development and developments in eastern Sukko) (see Table 20.4).

The area of the Russkaya CS development would equate to approximately <2% (approximately 95 ha) of the total LCA within the Survey Area (approximately 4,241 ha). Thus the Russkaya CS development plus the Project would cover a combined area that equates to approximately <2.25% of the LCA area within the Survey Area. Therefore, these collective developments will only impact upon a minimal total area of the Undulating Plateau LCA. Furthermore, the undulating nature of this LCA result in concealed areas of land which can will largely hide developments such as the Russkaya CS and the Project landfall facilities from certain viewpoints. In addition, some of the impacts of construction upon the Undulating Plateau LCA will be reversible through the restoration of affected landscapes. Areas which are required to be left open of vegetation (the cumulative pipeline RoWs) will form features resembling unsealed tracks or roads, which are already a characteristic feature within landscape, as such tracks form the majority of the access routes to agricultural / viticultural fields.

Overall, it is considered that the collective impact upon the Undulating Plateau LCA remains Moderate Adverse, with a moderate change in localised areas which would not compromise the overall integrity of the LCA. It is also considered that the LCA has the capacity to absorb these developments. As such, the impacts of these developments would not act together with the Project’s impacts to create a more significant overall landscape impact, thus indicating that cumulative impacts upon landscape character would be avoided.

20.7.6.2 Visual Receptors

Table 20.12 considers the potential for cumulative impacts at the various visual receptors scoped into the cumulative landscape and visual impact assessment during the Construction and Pre-Commissioning Phase.

Chapter 20 Cumulative Impact Assessment

The section above indicates that during the Project Construction Phase, the Project’s impacts upon sensitive visual receptors would not be elevated by the other developments in the area, indicating that cumulative impacts would be avoided.

20.7.7 Socio-economics and Community Health and Safety

Chapter 14 Socio-Economics (as summarised in Table 20.2) indicates that the Project is anticipated to generate some limited beneficial impacts at the local level as a result of employment generation whilst local and regional businesses are likely to receive some limited benefits from spending on local accommodation, goods, services and facilities during the Construction and Pre-Commissioning Phase. During the Operational Phase, beneficial impacts are anticipated to be at the national level only and associated with increased demand for Russian gas and increased government revenues, taxes and royalties.

Project impacts associated with reduced revenues for tourism-related businesses, including Shingari and Don holiday complexes and also those comprising the Anapa Resort Town tourism sector, due to construction activity and economic displacement due to changes in land use have been assessed as Not Significant. Impacts associated with reduced revenues for the Varvarovka Horse Riding Business, under a worst-case scenario due to the potential severance of a horse riding route used by the business during the Construction Phase, have been assessed as Low Adverse. Potential impacts on public safety and security, on the amenity of recreational users of Sukko and Shingari beaches, and on the amenity of visitors to Varvarovka Cemetery have been assessed as Low Adverse (Construction and Pre-Commissioning Phase). Impacts on the amenity experienced by residents in north east Varvarovka, during the Construction and Pre-Commissioning Phase due to noise and visual impacts, have been assessed as Moderate Adverse. During the Operational Phase of the Project, the socio-economic impacts on property owners associated with the creation of the safety exclusion zones are assessed to be Not Significant.

Given that the majority of residual socio-economic adverse impacts are either Not Significant or Low Adverse, the Project has limited potential to contribute to an adverse socio-economic cumulative impact (see Table 20.4). Similarly, the Project’s contribution to beneficial cumulative impacts is also limited. Nevertheless, the sections below discuss potential cumulative socio-economic impacts associated with the Construction and Pre-Commissioning Phase and the Operational Phase.

20.7.7.1 Construction and Pre-Commissioning Phase

All of the development proposals as detailed in Section 20.6.2 (and Table 20.4) have the potential to generate additional employment and additional demand for goods and services in the municipal district, and potentially further afield. Specific to the Russkaya CS, the EIA (Ref. 20.3 and Ref. 20.4) states that the creation of new jobs in the construction industry and more jobs in the service sector will result in positive impacts at a regional level. It further states that local companies may benefit from supplying construction related goods, equipment and services during construction of the development, as well as from increased demand arising from the presence of a non-local workforce. While the precise scale of increased employment and additional demand for goods and services associated with the Russkaya CS is not known, it is
likely to amplify the limited beneficial economic impacts associated with the Project for local communities. It is, therefore, expected that the beneficial impact of the Project on local employment and the demand for goods and services would be elevated by the other cumulative development proposals.

Chapter 14 Socio-Economics identified the potential for Not Significant and Low Adverse economic and community-related residual impacts on several receptors in relation to construction works in the nearshore and offshore sections; this included the Shingari and Don Holiday Complexes, the Anapa Resort Town tourism sector, the Varvarovka Horse Riding Business, as well as due to amenity impacts on recreational users of Sukko and Shingari beaches and also visitors to the Varvarovka Cemetery. However, most of the developments scoped into the CIA located in the Anapa Resort Town municipal district are not located within view of the coast at the Shingari Holiday Complex and Sukko Beach, nor will they have any indirect impacts on the coastal environment. The potential Anapolis development will be located adjacent to the Shingari Holiday Complex, however, it is considered most likely that this development’s construction phase will occur after the Project, thus avoiding the potential for Construction Phase cumulative impacts. Furthermore, the visual impact assessment has also concluded that cumulative impacts on assessed recreational and tourism-related receptors would not be significant. Therefore, other development proposals in the vicinity of the Project are not anticipated to give rise to any adverse economic cumulative impacts on these receptors.

With regard to the impact on the Varvarovka Horse Riding Business, the assessment was based on a potential worst-case scenario due to the lack of clear understanding of the precise alignment of the routes used by the business; with a commitment made to work with the horse riding business to undertake further investigation and, if necessary, to identify a suitable alternative route. This mitigation, if required, would also consider the location of cumulative developments to ensure that any identified alternative route was not compromised by such developments. It is expected that having regard to cumulative developments in this way would ensure that impacts on the business would not be exacerbated as a result of any cumulative development.

The socio-economic assessment has also identified the potential for Moderate Adverse amenity-related impact on residents in north east Varvarovka. This assessment has been concluded on the basis of the results of the noise and visual impact assessments; which have shown the potential for low and moderate adverse residual impacts. In both cases, the cumulative assessments for noise and visual (see Section 20.7.3 and Section 20.7.6) have concluded that the other developments scoped into the CIA would not be likely to add to or exacerbate such impacts upon residents in north east Varvarovka. Accordingly, it is concluded that there would be no additional cumulative amenity-related impacts on residential receptors in north east Varvarovka.

With regard to impacts on land users, the Russkaya CS, Lesnaya Polyana and Anapolis developments are being developed on former agricultural fields, removing those fields from agricultural use. Specific to the Russkaya CS, the EIA (Ref. 20.3 and 20.4) has stated that the impact on agricultural land will be negligible, in part due to the temporary nature of the impact and also due to mitigation, including compensation and re-cultivation of the affected land, which will be applied. In the case of the other two sites, the site land and surrounding land is all owned and managed by the same parent company.
It is presumed that for the Russkaya CS, all of the associated impacts have been subject to (or will be subject to) the relevant regulatory requirements governing the process of change of land use and, where applicable, take up of land, including with regard to reimbursement in full for losses associated with the short-term and long-term cessation of existing land uses (as stated within the Russkaya CS EIA). Therefore, it is not expected that the developments scoped into the CIA will give rise to any adverse cumulative economic impacts in this regard.

With regard to impacts on the community due to the conduct of the workforce during the Project Construction and Pre-Commissioning Phase, it is possible that the construction workforce for some of the other development proposals will include at least a portion of non-local workers. Specific to the Russkaya CS, the EIA (Ref. 20.3 and 20.4) has stated that there is the potential for construction to require non-local workers from other areas of Krasnodar Krai. It is further known that a construction labour camp has been constructed to the north of Gai Kodzor for non-local workers for whom the construction site is too far from their usual place of residence to allow them to travel on a daily basis. The impact assessment for the Russkaya CS does not define the number of construction workers or assess the potential impact of the presence of the non-local workers on the health, safety and security of the local population, and it is not known if there is a management regime in place to govern the behaviour of the workers if and when they are out in neighbouring towns and villages. Therefore, it is possible that the presence of non-local workers could potentially lead to adverse impacts on public safety and security.

Given the mitigation measures as recommended in Chapter 15 Community Health, Safety and Security, the Project’s impacts resulting from the conduct of the construction workforce in the community and the spread of sexually transmitted infections (STIs) due to the influx of workers to the area are both assessed as being Low Adverse (see Chapter 15 Community Health, Safety and Security). Additional workers associated with other developments could potentially exacerbate these impacts. South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated mitigation approaches to minimise the potential for cumulative public health and security impacts as associated with the influx of construction workers and construction activities.

20.7.7.2 Commissioning and Operational Phase

Chapter 14 Socio-economics identified beneficial impacts arising from the increase in government revenues and increased demand for goods and services associated with the gas extraction industry in Russia. Specific to the Russkaya CS, the EIA (Ref. 20.3 and 20.4) identified long term economic beneficial effects for Russia due to increased potential for gas exports, and the potential for associated increases in foreign current revenues and tax revenues for the (Russian Federal) state budget. However, as the assessment of beneficial impacts presented in Chapter 14 assumed completion and operation of the entire South Stream Pipeline System, the cumulative impacts of the Russkaya CS have already been accounted for.

With regard to impacts on land use associated with the operational safety exclusion zones, the Russkaya CS will not itself directly impact on the same land as impacted by the Project. Additionally, the compressor station and the pipelines leading from it westwards to the Project landfall facilities are entirely surrounded by forest, and so the creation of any similar safety
exclusion zones (if designated) would not restrict any commercial or residential land uses. The remaining other developments scoped into the CIA will not have any impacts in this regard.

20.7.8 **Ecosystem Services**

As detailed in Section 20.3 the CIA methodology considers VECs which are environmental and social attributes that should "reflect public concern for social, cultural, economic or aesthetic values, and also the scientific concerns of the professional community" (Ref. 20.2). There are therefore strong parallels between VECs and ecosystem services, where the type and level of service provision (and the value this confers) is determined by:

- The condition of the underlying habitat or ecosystem type;
- The functioning of ecosystem processes and the interactions between them; and
- The importance of the services to beneficiaries (in terms of livelihoods, health, safety, and cultural heritage) and the Project (in terms of social, operational, financial, regulatory, and reputational risks).

IFC PS1 limits the cumulative impacts to be addressed to "those impacts generally recognised as important on the basis of scientific concerns and / or concerns from Affected Communities" (Ref. 20.1). The CIA is therefore concerned with assessing the incremental impact of the Project on priority ecosystem services and their beneficiaries in relation to the combined impacts of multiple developments. For the purposes of this assessment, VECs are therefore defined as the priority ecosystem services as identified in **Chapter 17 Ecosystem Services**.

Chapter 17 describes residual impacts upon the following ecosystem services: crops, capture fisheries, water (supply), hazard regulation, air quality regulation, water quality regulation, soil quality regulation, tourism and recreation values, cultural and spiritual values and wild species diversity). As summarised in Table 20.2, all residual impacts are predicted to be either Not Significant or Low Adverse during all Project phases. This indicates that the Project’s ability to contribute to a cumulative impact upon ecosystem services in the vicinity of the Project with other potential developments scoped into the CIA is limited.

However, as detailed in Section 20.4, where there are Low Adverse residual impacts, further evaluation has been undertaken to see if there is scope for cumulative impacts to be generated, for the following ecosystem services:

- **Crops**: Project clearance of agricultural land, restrictions on re-use, dust released during construction activities and leaks or spills could result in a Low Adverse impact on crop production, and the associated loss of jobs. As indicated in **Chapter 17 Ecosystem Services**, the Project will result in around 8.7 ha of agricultural land being taken out of agricultural use permanently, 23.75 ha will require temporary clearance before being returned to the land owner following the Construction Phase, whilst 21.05 ha will be returned to the landowners, but future use will be restricted;

- The Russkaya CS, Lesnaya Polyana, Anapolis and Club Village developments will all impact upon some agricultural areas, thus removing further land from agricultural use. The Russkaya CS development could impact upon approximately 21.9 ha of agricultural land – although the Russkaya CS EIA (Ref. 20.3 and 20.4) states that the residual impact on
agriculture would be negligible given that: damage will be compensated in accordance with Russian law; some impacts will be temporary; and upon completion of construction, some land will be re-cultivated and returned to the land users in a condition suitable for agriculture. The Lesnaya Polyana development is understood to have already resulted in land being cleared, whilst the Anapolis development is estimated to result in the loss of approximately 13.1 ha of agricultural land (see Table 20.9) and Club Village Chateau development will potentially remove approximately 14.4 ha of vineyards (see Table 20.10). These developments will all result in additional losses of agricultural land. However, with the implementation of defined Russkaya CS mitigation proposals, and given that the Lesnaya Polyana, Anapolis and Club Village Chateau sites are all owned by the same developer who is potentially able to absorb any displaced workforce at other owned sites, significant cumulative impacts upon this ecosystem service are not anticipated;

- **Hazard Regulation:** Activities such as ground works, vegetation clearance, and changes to topography undertaken for the proposed developments scoped into the CIA could have a collective impact on soils and water flows in the area which could potentially increase the risk of hazards such as flooding and landslides to beneficiaries living and working within the Local Area. However, as set out in Section 20.7.1, there are unlikely to be any significant cumulative soil or water resource impacts as generated by the Project and the Lesnaya Polyana, Club Village Chateau or Anapolis developments. With regard to the Russkaya CS, the mitigation measures set out for the Project (including restoration of natural vegetation) and those defined for the Russkaya CS development mean that any cumulative impacts on surface water flows and soil stability are likely to be of **Low Significance** due to the ephemeral nature of the watercourses in the catchment and the temporary duration of development construction activities;

- **Water Quality Regulation:** As identified in Chapter 17 Ecosystem Services, the main impacts on the regulation of water quality are likely to arise in the marine environment due to disturbance of sediment during dredging processes and potential leaks and spills. Since none of the proposed developments have a marine component, significant cumulative impacts on marine water quality regulation will be avoided. Within the terrestrial environment, vegetation clearance together with increased risk of spillages from other developments scoped into the CIA could potentially have a greater cumulative impact on the regulation of surface water quality (e.g. potential cumulative impacts on the Shingari River arising from the Project (microtunnelling site) and developments such as Lesnaya Polyana, Club Village Chateau and Anapolis). However, as set out Section 20.7.1, the low likelihood of spillages, differences in the development construction schedules, together with the localised and temporary nature of any water quality impacts suggests that cumulative impacts are unlikely to be significant. As such there are not likely to be any significant cumulative impacts on the regulation of marine and fresh water quality or those who benefit from this service;

- **Tourism and Recreation Values:** The developments scoped into the CIA and Project together are unlikely to have any cumulative impact on the provision of, or access to, tourism and recreation services (e.g. through loss of access to recreational areas). However, there are potential impacts upon the quality of tourism and recreation services due to cumulative impacts on the prevailing landscape character and visually sensitive human receptors during construction and operation. As discussed in Section 20.7.6 and Section
20.7.7, any such visual impacts are not likely to be significant due to the distance of developments from the receptors, the ability of the natural environment to absorb visual impacts of development, and the difference in timing schedules of the developments.

Given this, it is considered that the cumulative impacts of the Project and the developments scoped into the CIA are unlikely to have a significant lasting impact on the ability of any residents or visitors to benefit from the recreational and tourism opportunities provided by the affected ecosystems; and

- **Cultural and Spiritual Values:** The developments scoped into the CIA have the potential to affect the provision of cultural and spiritual values through impacts upon the prevailing landscape character within which sites and features of cultural and spiritual significance reside. However, as set out in Section 20.7.6, the cumulative impact of the collective developments will only impact a small area of the landscape. Furthermore, the undulating nature of the landscape is effective at absorbing such developments and habitat restoration activities will further reduce any impacts. Potential human receptors identified in Chapter 17 Ecosystem Services who benefit from this service include visitors to the Varvarovka cemetery who are likely to be subject to visual and noise disturbance. However, at a distance of over 3.7 km, the construction of the Russkaya CS will form a barely perceptible element of the views from this receptor and there are no other potential developments in the area that will be visible to cemetery visitors. However, the combined traffic from the Project and Russkaya CS may result in greater cumulative impact on visitors to the cemetery and in order to minimise such impacts South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated traffic management plans.

### 20.7.9 Cultural Heritage

**Chapter 16 Cultural Heritage** (as summarised in Table 20.2) reports residual cultural heritage impacts as follows:

- Residual impacts predicted to be **Not Significant** or **Low Adverse** for all terrestrial cultural heritage features, with impacts mainly being related to ground disturbance and increases in construction traffic; and

- Residual impacts predicted to be **Not Significant** or **Low Adverse** for marine cultural heritage features, except Moderate Adverse impacts upon RU-MCH-003 amphora and RU-MCH-004 wooden shipwreck.

All terrestrial cultural heritage residual impacts are predicted to be either **Not Significant** or **Low Adverse** during all Project phases. Given that none of the developments scoped into the CIA (see Table 20.4) will have a direct impact upon any of these defined terrestrial cultural heritage features indicates that cumulative impacts will be avoided.

However, the construction vehicles servicing the Russkaya CS development will use some of the same access routes used by the Project, including a permanent access route that will be constructed by Gazprom Invest. This permanent access road will be located in proximity of a known cultural heritage receptor (the Varvarovka Russian and Armenian cemetery (RU-TCH-06)), but its route has been selected to avoid running directly alongside the cemetery.
(Chapter 16 Cultural Heritage). Due to the road alignment, visitors to the cemetery will experience an impact of negligible magnitude (resulting in residual impact of Not Significant) due to the Project. Nevertheless, the combined traffic from the Project and Russkaya CS may result in greater cumulative impact on visitors to the cemetery and in order to minimise such impacts South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated traffic management plans.

With regard to marine cultural heritage, none of the developments scoped into the CIA involve significant marine construction activities or seabed intervention works (noting that the Russkaya CS development will involve the use of marine vessels for materials supply which are not anticipated to impact upon marine cultural heritage) (see Table 20.4). As such, it is considered that no potentially significant cumulative cultural heritage impacts will occur (both Construction and Pre-Commissioning Phase and Operational Phase).

As noted in Table 20.3, with regard to potential Rosneft oil and gas exploration activities, South Stream Transport intends to liaise with Rosneft with the aim of minimising the potential for cumulative marine environmental impacts that might result from any simultaneous activities.

20.7.10 Waste Management

Chapter 18 Waste Management included an assessment of waste management impacts arising from the Project waste streams that will be produced during the Construction and Pre-Commissioning Phase and during the Operational Phase. The chapter indicated that residual waste impacts would generally be Not Significant to Low Adverse following the preparation and implementation of a comprehensive integrated Waste Management Plan (described in Chapter 22 Environmental and Social Management). However, Chapter 18 Waste Management indicates that the main regional landfill site (Alfa landfill) is not designed or operated as an engineered landfill in accordance with GIIP, and hence has been identified as being a sub-optimal waste disposal facility. As a result, any Project waste disposed of at the Alfa landfill would result in a Moderate Adverse impact (due to waste disposal in an unlined landfill). Alfa landfill is due to be replaced once it ceases operation in 2016, and thereafter the replacement landfill would be used by the Project. This is expected to be an engineered facility (although its location is yet to be confirmed by the local government).

In the event that any Project wastes are deposited at Alfa landfill, the impacts are not expected to be environmentally significant. This is the case since the Project wastes that require landfill disposal are non-hazardous, whilst the waste quantities arising from the Project are relatively small (typically less than 1,000 tonnes per waste stream – refer to Chapter 18 Waste Management) and would form only a very small proportion of the overall waste disposed of at Alfa, such that they would not significantly increase any existing environmental impacts associated with the landfill site.

Of the developments scoped into the CIA (see Table 20.4), only the Russkaya CS is considered to be able to generate waste volumes that may add pressure on local waste storage and disposal facilities in the area. The Russkaya CS EIA (Ref. 20.3 and 20.4) indicates that during the construction phase some 502,484 tons of waste will be generated, and of this 27,734 tons will be subject to re-use or recycling at third-party enterprises, whilst 474,750 tons will be transferred to a specialized waste disposal enterprise. Assuming that the Alfa landfill is being
used by Russkaya CS developers, waste disposal practices may be adding to existing capacity issues at the landfill.

Given that the quantities of hazardous and non-hazardous waste arisings from the Project are so small when compared to total regional arisings, it is considered that the Project is not able to contribute to a significant cumulative waste management impact. Although large quantities of uncontaminated soil and rock will be generated by the Project, this is not expected to give rise to significant cumulative impacts since such materials will be used for backfill or restoration purposes at quarry or landfill sites in the region; and since the material is inert, it is unlikely to give rise to significant environmental impacts. South Stream Transport will seek to engage with Gazprom Invest to investigate the potential beneficial use of inert materials (soils or rock) generated by the Project and the Russkaya CS development.

20.7.11 Land-based Traffic and Transportation

The sections above present an evaluation of the potential cumulative impacts upon identified VECs that may occur as a result of Project interactions with various development proposals. This analysis has not identified any potentially significant cumulative environmental or social impacts with regard to land-based traffic and transportation during any Project phases (e.g. air quality, noise and vibration, cultural heritage etc.).

However, Appendix 9.1: Traffic and Transport Study indicates that the Project has the potential to increase traffic flows on some transportation links during the Construction and Pre-Commissioning Phase. Once the Pipeline is operational, traffic will be limited to servicing and maintenance vehicles - such low levels of traffic will not have a traffic impact.

Appendix 9.1 indicates that during the Construction Phase, the Project will generate traffic arising from the transportation of materials from a Russian Black Sea port. Pipes and equipment that are required for the landfall section will be delivered by existing roads to a point north of Gai Kodzor. A temporary bypass has been constructed for heavy construction vehicles to avoid this community and this will be used both by the vehicles related to the construction of the Russkaya CS development and Project vehicles. Workers may also have to be transferred to and from Anapa on a daily basis if they are accommodated in Anapa. There will also be a need to export excavated material that is not suitable as fill material, and to import suitable fill material to make up the shortfall in suitable material. The construction traffic has been estimated for a range of activities which indicates that over the predicted 25 month duration of the contract, there will be a total of over 110,000 traffic movements which averages at approximately 4,500 movements per month or 189 per day.

In terms of vehicle kilometres travelled by construction related traffic, a significant portion of trips will occur on the M25 either west or east of Rassvet. The geometry of the M25 and the current traffic flows are such that it is a satisfactory route to be used by construction traffic. Traffic flow impacts associated with construction traffic travelling between the junction on the M25 at Rassvet and the landfall site will be partially negated by the provision of the bypass to Gai Kodzor and the proposed link from the south of that settlement to the landfall site, which means that to the south of Rassvet the heavy construction traffic will avoid locations where there may be sensitive receptors.
The section of the road between Rassvet and the northern end of the temporary construction bypass of Gai Kodzor could experience increases in traffic flow of up to 30% with an increase in the number of heavy construction vehicles approaching 200%.

It is noted that the road through Rassvet already carries appreciable levels of heavy goods vehicles associated with the construction works of the Russkaya CS development. Therefore, the traffic associated with the Project will be an extension of an existing impact, rather than the introduction of a new impact. The traffic assessment concludes that with the provision of the construction traffic bypasses, the highway network is capable of accommodating the additional traffic without there being any perceptible impact on other road users with the exception of the section of route through Rassvet.

Given the details presented above, it is considered that Project construction will result in increases in traffic on some transportation links that are currently being used by Russkaya CS construction traffic. The Project will thus contribute to a potential cumulative increase in traffic flows through Rassvet. The Project includes a range of mitigation measures that aim to minimise the environmental and social consequences of traffic flow increases through Rassvet (refer to Chapter 15 Community Health, Safety and Security). However, there is also a commitment to further assessment of potential impacts and investigation of additional mitigation measures, if needed. South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated construction traffic management plans.

### 20.8 Cumulative Impact Mitigation, Monitoring and Management

The CIA has not identified any cumulative environmental or social impacts that are considered to be significant and in need of specific mitigation measures, monitoring or management beyond those already being undertaken for the Project (see Chapter 22 Environmental and Social Management). However, the assessment has made a number of recommendations with regard to the alignment of mitigation strategies with local developers – this includes the following:

- South Stream Transport will seek to engage with Gazprom Invest with the aim of aligning Gazprom Invest’s ecological mitigation strategy and mitigation measures as related to the Russkaya CS development with those of the Project. Of particular importance should be the avoidance of impacts through the sensitive timings of works (including the herpetiles hibernation period), implementation of herpetile fencing and a programme of translocation, and adherence to good industry practice as well as to develop measures that would enhance biodiversity management within the wider area;

- South Stream Transport will seek to engage with Gazprom Invest to investigate the potential beneficial use of inert materials (soils or rock) generated by the Project and the Russkaya CS development;

- South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated traffic management plans;

- South Stream Transport will engage with the Anapolis and the Club Village Chateau developers with the aim of aligning the developers’ mitigation measures with those of the
Project. Furthermore, in developing their BAP, South Stream Transport will engage with these developers with an aim to develop measures that would enhance biodiversity management within the wider area;

- South Stream Transport will liaise with Gazprom Invest with the aim of developing aligned and coordinated mitigation approaches to minimise the potential for cumulative public health and security impacts as associated with the influx of construction workers and construction activities; and

- South Stream Transport will seek to further liaise with Rosneft with the aim of minimising the potential for any cumulative marine environmental impacts that might result from any simultaneous activities.

20.9 Assumptions and Limitations

This CIA has been undertaken based upon the available information contained within this ESIA Report. Key assumptions and limitations are detailed below:

- The CIA is restricted to Russian VECs and only concerns potential cumulative impacts associated with the Project (i.e. within Russia);

- The assessment only considers residual impacts after the implementation of mitigation measures as detailed in this ESIA Report;

- The assessment has not considered unplanned events as discussed in Chapter 19 Unplanned Events;

- Details regarding some land development projects within the vicinity of the Project are limited, whilst several have not been subject to any formal environmental impact assessment process. This has limited the CIA to only consider potential cumulative impacts on a qualitative basis in some cases; and

- The CIA excludes potential cumulative impacts during the Decommissioning Phase given that the decommissioning programme is uncertain and will only be developed during the Operational Phase of the Project, whilst other developments that may be taking place at the same time as decommissioning activities are also unknown.

20.10 Conclusions

Whilst there are a number of developments in the near vicinity of the Project, such as the Russkaya CS development and various residential developments, this CIA has not identified any adverse environmental or social cumulative impacts that are considered to be significant and in need of specific mitigation measures, monitoring or management by the Project, although various recommendations are made with regard to the alignment of local developers’ mitigation strategies with those of Project.

21 Transboundary Impact Assessment

21.1 Introduction

Transboundary impacts may be considered as "impacts that extend to multiple countries, beyond the host country of the project, but are not global in nature. Examples include air pollution extending to multiple countries, use or pollution of international waterways, and transboundary epidemic disease transmission" (Ref. 21.1).

As the South Stream Offshore Pipeline spans multiple countries and is being constructed across a dynamic marine environment, there is the potential for some Project activities to generate transboundary impacts. Such impacts may arise from Project activities which traverse country boundaries, or impacts that originate within one country, but have the ability to extend across national borders.

This chapter considers the potential for transboundary impacts resulting from the Project. Where applicable, the chapter draws upon the impact assessments conducted in each of the technical discipline sections of this Environmental and Social Impact Assessment (ESIA) Report (Chapters 8 - 18).

Given that greenhouse gas emissions are a global issue as opposed to a transboundary concern, this chapter does not include a Project-related greenhouse gas assessment – details regarding greenhouse gas emissions as associated with Project activities are provided in Chapter 9 Air Quality.

21.2 Frameworks for Considering Transboundary Impacts

21.2.1 International Finance Corporation (IFC)

IFC Performance Standard (PS) 1 Assessment and Management of Environmental and Social Risks and Impacts (Ref. 21.2) recognises the need to consider transboundary impacts. PS 1 states that the risks and impacts identification process needs to consider "potential transboundary effects, such as pollution of air; or use or pollution of international waterways".

21.2.2 Espoo Convention

As detailed in Chapter 2 Policy, Regulatory and Administrative Framework, the Convention on Environmental Impact Assessment (EIA) in a Transboundary Context, 1991 (Espoo Convention) came into force internationally on 10 September 1997 (Ref. 21.3). The Russian Federation signed the Espoo Convention in 1991; however, the Espoo Convention has not been ratified by Russia. The Federal Government is currently planning transposition of the Convention requirements into Russian legislation.
The main objective of the Espoo Convention is to promote environmentally sustainable economic development, as a preventative measure against transboundary environmental degradation. The Espoo Convention stipulates obligations of parties to assess the transboundary environmental impacts of a project in the early planning stages.

The Espoo Convention specifies the obligation of Parties of Origin to notify and consult Affected Parties when a project in their territory is likely to have a significant adverse transboundary impact. Parties of Origin can ask the developer to undertake further public consultation, in addition to normal EIA requirements.

Bulgaria is the only host country of the South Stream Offshore Pipeline to have ratified the Espoo Convention. The Bulgarian government notified Romania during the Bulgarian Scoping Stage of the Project as the only other country signatory to the Espoo convention of all the Black Sea littoral countries potentially affected by the Project; Romania decided not to participate in accordance with the Convention.

### 21.3 Potential for Transboundary Impacts

In order to generate a transboundary impact, activities from the Project would need to generate an impact that has the potential to cross national jurisdictions as defined by the Exclusive Economic Zone (EEZ) boundaries and land borders of the Black Sea countries. Figure 21.1 illustrates the closest points of the Project to these boundaries and to land territories of nearby countries.

It is acknowledged that some Project activities will be located closer to EEZ boundaries and Black Sea country land borders than indicated in Table 21.1. This includes Project-related vehicle movements from the selected ports, as well as marine supply vessel movements. With regard to marine supply vessels, these are likely to use existing international shipping routes to and from the selected ports (as shown on Figure 21.2).

Impact Assessment Methodology

The various technical assessments as presented within this ESIA Report (Chapters 8 - 18) have used defined impact assessment methodologies to quantify Project impacts upon defined sensitive receptors. In undertaking this task, these assessments have considered the potential for identified impacts during the various Project phases (Construction and Pre-Commissioning Phase, Operational (including Commissioning) Phase and Decommissioning Phase) to traverse international borders. This chapter captures the findings of the earlier chapters in so far as they relate to transboundary impacts and considers both planned activities and unplanned events.

In general, potential impacts generated by planned activities during the Construction and Pre-Commissioning Phase of the Project will typically be temporary in nature and localised in extent. Similarly impacts generated from planned activities during the Operational Phase will also be localised. However, during the various Project Phases there is the potential for unplanned events which are those events that are unintended and that may pose risks to human health and/or the environment, including its socio-economic components (Chapter 19 Unplanned Events) that may result in wider transboundary impacts. Unplanned events include the...
accidental release of hydrocarbons (e.g. spills of fuel from vessels) to the marine environment during the Construction and Pre-Commissioning Phase and the accidental release of natural gas to the atmosphere in the event that the Pipeline is damaged during the Operational Phase. Such events have a low risk of occurrence and strict management measures will be put in place to ensure that risks are minimised and any resultant impacts are also minimised (Chapter 19 Unplanned Events).

The sections below consider the potential for transboundary impacts from both planned and unplanned events during the Construction and Pre-Commissioning Phase and Operational Phases of the Project. The activities to be undertaken during the Decommissioning Phase are uncertain, as decommissioning proposals will be developed during the Operational Phase of the Project. Current Good International Industry Practice (GIIP) is to decommission pipelines in place, with few resultant environmental impacts. However, should a decision be made to remove the pipelines and the associated infrastructure, it is expected that the potential transboundary impacts and mitigation measures will be similar in nature to some of those as described herein for the Construction and Pre-Commissioning Phase of the Project. As such, the Decommissioning Phase is not specifically covered in this chapter.

21.5 Potential Terrestrial Transboundary Impacts

21.5.1 Planned Activities

Chapters 8 to 18 have predicted potential impacts on terrestrial sensitive receptors during the various Project Phases. These assessments have identified that due to the distances between planned Project activities and the land territories of Turkey, Georgia and Ukraine (i.e. greater than 74 km), predicted impacts do not have the potential to cross territorial borders and have a transboundary environmental impact. This includes potential transboundary air quality impacts as associated with the transportation of resources to and from the construction sites during the Construction and Pre-Commissioning Phase of the Project. Chapter 11 Terrestrial Ecology also considers and concludes that there will not be transboundary impacts upon migratory birds given that the Project will not have significant adverse direct or indirect impacts upon migratory bird species during planned activities.

21.5.2 Unplanned Events

Chapter 19 Unplanned Events considers the various unplanned events that could occur during the different Project Phases and the actions that are to be taken to minimise the occurrence of such events and their associated environmental and socio-economic consequences. A review of these unplanned events indicates that the only potential terrestrial unplanned event that could have a transboundary environmental impact results from the release of non-combusted gas either following pipeline rupture or due to the unplanned need to vent gas from the pipeline (depressurise) to ensure overall system safety. However, Chapter 9 Air Quality indicates that such events would not pose a risk to the health of residents at nearby receptors and that any impacts would be localised – it thus follows that such unplanned events would not be able to generate a transboundary air quality impact given the distance from the pipeline to the land territories of Turkey, Georgia and Ukraine.
21.6 Potential Marine Transboundary Impacts

21.6.1 Planned Activities

It is anticipated that some planned Project activities (e.g. operation of plant and equipment) have the potential to result in marine transboundary environmental impacts given that such Project activities will be taking place close to and across EEZ boundaries. A number of marine activities and environmental aspects with the potential to cause adverse transboundary impacts have been identified and are discussed below:

- Impacts on air quality;
- Impacts from waste generation;
- Impacts from underwater noise upon fish and marine mammals;
- Impacts on migratory birds; and
- Impacts on fish migration and fisheries.

21.6.1.1 Air Quality

It may be necessary to source materials (such as rock material) and fuel from outside Russia for Project use within Russia and Russian waters (Chapter 5 Project Description). The sources for these materials have not yet been confirmed.

Chapter 9 Air Quality indicates that air emissions from marine vessels have the ability to affect air quality due to the emission of carbon monoxide (CO), nitrogen dioxide (NO₂), particulate matter (PM), and sulphur dioxide (SO₂), although such vessel emissions will not result in an environmental impact offshore where there are no relevant sensitive receptors. Marine vessel usage in the vicinity of EEZ borders is thus not able to exert an air quality related transboundary impact given the absence of sensitive receptors. In addition, low intensity vessel usage for material delivery and fuel transportation via other countries is not anticipated to result in any significant air quality impacts upon any transboundary sensitive receptors. Similarly, transnational marine vessel use during the Operational Phase of the Project as associated with material supply and maintenance activities are not anticipated to result in any transboundary air quality impacts given the low volume of marine vessels involved in such activities.

21.6.1.2 Waste Generation

Waste material will be generated on board the pipe-laying and other vessels throughout the Construction and Pre-Commissioning Phase and to a lesser extent during the Operational Phase (Chapter 18 Waste Management). Materials will be transported to the pipe-laying vessel by supply vessels, which will also be responsible for the removal of any waste material and its subsequent transportation to the shore (e.g. using existing port waste reception facilities at selected ports).

Supply vessels may originate from several countries and not just from Russia and in some circumstances waste may be temporarily stored on board pipe-lay vessels, prior to subsequent transportation for disposal via a port outside of Russia. It is normal practice in the shipping
industry for port waste reception facilities to receive waste from vessels using that port, where the waste has been generated during the ship’s voyage including transit outside of the waters of the receiving country. The amount of waste that will be generated within Russian waters and transported to ports in other countries is uncertain and is dependent upon which ports are selected by the Project.

Irrespective of the location and quantity of waste generated, the Project will comply with the International Convention for the Prevention of Pollution from Ships (MARPOL) Annexes 1, IV and V (Ref. 21.4 and Ref. 21.5), each of which includes specific waste management provisions, as well as the national requirements of the recipient country. All hazardous waste will be disposed of at licenced facilities. Waste mitigation measures to be applied are detailed in Chapter 18 Waste Management.

Adherence to MARPOL will enable significant adverse transboundary impacts associated with Project waste to be avoided.

21.6.1.3 Underwater Noise Impacts upon Fish and Marine Mammals

An increase in maritime traffic and other Project activities such as micro-tunnelling, rock placement and pipe-laying, will result in an increase in underwater noise levels during the Project Construction and Pre-Commissioning Phase which may impact upon ecological receptors (e.g. fish and marine mammals).

The acoustically sensitive receptors in the Black Sea are the fish species categorised as ‘hearing specialists’ and marine mammals. None of the sensitive fish species are protected, but all marine mammal species such as the bottlenose dolphin, common dolphin and harbour porpoise that are found in the Black Sea are of conservation concern (Chapter 12 Marine Ecology). The potential for Project construction activities in Russian waters to impact upon acoustically sensitive ecological receptors located across EEZ boundaries (principally in Turkish waters) thus needs to be considered. As reported in Chapter 12 Marine Ecology, some Project activities such as pipe-laying and trenching will increase underwater noise levels. The noise levels associated with such activities are most likely to cause mild avoidance or harassment reactions rather than strong behavioural reactions and injury. Project activities that generate underwater noise resulting in mild avoidance or harassment reactions means that the fish or marine mammals may be aware of the sound, but does not imply that they will move or be impacted. Chapter 12 Marine Ecology indicates that no impacts are predicted to hearing generalist species. Hearing specialist fish are generally more sensitive to underwater noise and behavioural effects may be apparent in some species such as sprat or kilka in some situations (though not shad or anchovy). The maximum predicted range for behavioural effects in hearing specialist fish is 260 m. Chapter 12 Marine Ecology also reports that underwater noise arising from several vessels simultaneously were insufficient to give rise to mortality in marine mammals. The injury footprint of proposed construction operations is estimated to be very limited. Porpoise in close proximity to pipe-laying (20 – 60 m) may experience permanent
threshold shift (PTS)\(^1\) although in reality it is unlikely that cetaceans will approach loud sound sources. Based on audiogram weighted criteria, mild behavioural effect ranges for individual vessel operations are only estimated to be significant for dolphins and porpoises, to a maximum range of 0.72 km for dolphins and 1.5 km for porpoise at any modelled location.

Whilst Project construction activities have the potential to generate underwater noise, and thus impact upon fish and marine mammal behaviour, the limited spatial extent of strong avoidance reactions is such that significant transboundary impacts would be avoided. For example, given that construction activities would be located at least 8 km from the Ukrainian EEZ boundary (see Table 21.1), Project construction activities are not anticipated to be able to impact upon fish or marine mammals in Ukrainian waters. Similarly, there would be no impacts upon fish or marine mammals in Georgian waters. Construction activities close to the Turkish EEZ boundary would be able to generate avoidance reactions (fish and marine mammals) as per the limited distances as detailed above, noting that such impacts would be less than those as associated with project construction activities that will be undertaken within Turkish waters.

During the Operational Phase, given that underwater noise levels will be lower than those experienced during the Construction Phase, significant transboundary ecological impacts are not anticipated.

### 21.6.1.4 Birds

The Black Sea coastline is a major migratory route for birds (Chapter 12 Marine Ecology). There are two periods for migration in the north-eastern Black Sea region; one during the spring (mid-February to early-June) and one in the autumn (early-August to end-November). The pipeline construction corridor in the offshore sections is approximately 2 to 3 km wide, and will cross only a small part of the migratory route (as migratory routes run in a north to south direction). In addition, the Construction and Pre-Commissioning Phase is temporary in nature and the scale of the construction corridor is very small. This means that the Project will not result in the formation of any barriers that could result in a change to bird migration patterns (Chapter 12 Marine Ecology). As a result, Construction and Pre-Commissioning Phase activities will not cause long term levels of disturbance to migratory birds or the ecological features upon which they depend. Similarly, Operational Phase activities are not anticipated to impact upon bird migration. Overall, no significant adverse impacts to the transboundary activities of migratory birds are expected as a result of planned Project activities.

### 21.6.1.5 Fisheries

The fish stock in the Black Sea has been drastically reduced as a consequence of eutrophication, overfishing and plankton reduction (Chapter 14 Socio-Economics). Nevertheless, fishing is still a substantial source of revenue for Black Sea countries.

\(^1\) Defined as the onset of permanent threshold shift (PTS) which is the point at which hearing may become impaired and from which the animal cannot recover
The majority of Project activities will take place in areas where only pelagic fishing can take place, because of the absence of any species at depths in excess of approximately 150 m, below which the Black Sea is anoxic. Pelagic fishing involves commercial species such as the European anchovy (*Engraulis encrasicolus*), sprat (*Sprattus sprattus*), and Black Sea horse mackerel (*Trachurus mediterraneus ponticus*). Given this distribution, it is the activities in the shallower parts of the offshore section and in the nearshore section of the Project that are more likely to interact with both fish populations and commercial fishing in Russian waters.

Any impacts upon migratory fish species, such as anchovy, would have the potential to influence fisheries in other Black Sea countries. Potential impacts could occur as a result of construction activities such as pipe-laying, dredging and post lay trenching which result in underwater noise, generation of suspended sediments and the loss of habitat. Anchoring, pipe-laying, dredging and post lay trenching will generate sediment plumes, which will be of limited duration and dimension. These plumes will not occupy a significant proportion of the local water column and it is anticipated that fish will avoid them. The loss of habitat from pipe-laying is considered insignificant in the context of the wider Black Sea environment and is thus not expected to result in an impact on either migratory or non-migratory fish.

Given the limited area the offshore and nearshore sections of the Project will occupy, and the temporary nature of the Construction and Commissioning Phase, no significant transboundary impacts to fish stocks and fisheries are expected.

**21.6.2 Unplanned Events**

Unplanned events are considered separately from planned activities as they would only arise as a result of a technical failure, human error or as a result of natural phenomena such as a seismic event ([Chapter 19 Unplanned Events](#)). Unplanned events that are considered to have the potential to generate a transboundary marine impact include (with each being discussed in the sections below):

- Disruption or damage to non-Project subsea infrastructure (principally during the Construction Phase);
- Increase on maritime traffic causing accidents;
- Hydrocarbon spillages (as a result of maritime accident/collision) (principally during the Construction and Pre-Commissioning Phase);
- Vessel operations have the potential to inadvertently introduce invasive alien species, either in ballast water, on the biofilm inside ballast tanks or carried as fouling organisms on the hull; and
- Large scale release of gas (during the Operational Phase).

**21.6.2.1 Disruption to Subsea Infrastructure**

As shown in Figure 21.3, existing subsea infrastructure cables cross the Black Sea (including three subsea infrastructure cables which pass through the Russian EEZ). Consequently, there is a risk that during the Construction Phase pipe-laying activities that a cable could be damaged.
which would have a potential adverse transboundary impacts upon other Black Sea countries due to service interruption.

To mitigate the potential damage to subsea infrastructure cables, it will be necessary to install structures above the existing cables to ensure their protection. Such protective structures could include concrete or rock mattresses. South Stream Transport will contact known cable owners prior to pipe-laying and agree technical and commercial aspects of any such cable crossings.

With the implementation of the defined mitigation approach, the risks of damaging subsea infrastructure cables and associated transboundary impacts (i.e. disruption to communication networks) will be minimised.

**Figure 21.3 Location of Subsea Cables**

---

21.6.2.2 Increase in Marine Traffic

Project related maritime traffic and navigation restrictions have the potential to increase the risk of marine vessel collisions or obstruct other vessels traversing the Black Sea (originating from or en route to ports outside of Russian Federation territory). However, the pipe-laying spreads (pipe-laying and supporting vessels (Chapter 5 Project Description)) will move at very low speeds (i.e. around two nautical miles a day), which means that they can effectively be considered to be stationary objects rather than moving vessels. Consequently non-Project vessels can be notified of the spread’s daily position to minimise the risk of vessel collisions. In
addition, the Project will comply with all international mandatory requirements (e.g. MARPOL - Ref. 21.4 and Ref. 21.5), including the following measures:

- Prior to and during construction, liaise with the appropriate maritime authorities and ports to ensure suitable navigational warnings are issued; and
- Radio communications and other safety devices (such as navigational lights and maritime warnings) to communicate the location and extent of the exclusion zone around the Project construction activities.

With the implementation of such measures, the risk of third party vessel collisions is minimal and the Project’s activities are not expected to result in a significant impact on transboundary marine vessel movements. In avoiding the pipeline spread, non-Project vessels may be required to deviate from their preferred course, however, such deviations would not significantly disrupt vessels undertaking long range transnational journeys.

21.6.2.3 Maritime Accidents Leading to Oil Spills

Chapter 19 Unplanned Events considers the risks of Project vessel accidents and collisions and the potential environmental impacts from any resultant hydrocarbon spillages. The assessment was supported by a maritime risk assessment and hydrodynamic modelling of various oil spill scenarios. The maritime risk assessment indicates that the probability of vessel collisions (and vessel grounding in nearshore areas) occurring is considered to be very low. The probability that such incidents would result in an oil spill is even lower, as a high-energy collision would be required to damage a vessel to such an extent that marine diesel was spilled into the sea.

Hydrodynamic modelling has been undertaken for various oil spillage scenarios (Ref. 21.6), some of which can be used to illustrate the potential for transboundary impacts. Oil spillage modelling has been undertaken for an oil spillage along the Pipeline route very close to the Russian and Turkish EEZ border (spillage of 2,000 m³ of Marine Diesel Oil (MDO)).

Whilst the oil spillage release location for the modelling scenario as detailed above was located just outside the Russian EEZ border (see Figure 19.2), it is considered that the modelling results can be used to illustrate the potential for spillages within the Russian EEZ to generate potential transboundary impacts. Hydrodynamic modelling results illustrate the following (Chapter 19 Unplanned Events):

- **2,000 m³ MDO spillage on the Turkish / Russian EEZ border:** Hydrodynamic modelling predicts a moderate area of the Black Sea would be affected with a surface slick of thicknesses > 1 μm visible for up to 96 km from the release location. Thus an oil spillage along the Pipeline route close to the Russian EEZ border would have the potential to impact upon the marine waters of the Ukraine and Turkey within in a matter of hours. Dissolved water column concentrations of greater than 50 ppb are predicted a maximum of 68 km away from the release site, with concentrations taking up to 1.5 days to fall below this threshold in localised areas (oil is not expected to have acute toxic effects at water column concentrations less than 50 ppb). The risk of the oil spill reaching any shorelines is predicted to be low (up to 13%) due to the central location of the oil release and limited shoreward transport by prevailing currents. The minimum coastal arrival time for dissolved
oil is predicted to be around three days with a total mass onshore of approximately 85 tonnes - this quantity would be spread across a large coastal area such that concentrations would be likely to be very low - the majority of oil would arrive as fine droplets which are not expected to be visible. Russian and Ukrainian coastal locations would have the greatest exposure, although there may be very small quantities reaching Turkey and perhaps Georgia depending on tidal and weather conditions. Beaching after three days across a wide area of coastline suggests that any dissolved oil arriving onshore at the countries specified above would arrive in a weathered and dispersed state, only being noticeable in isolated areas. This modelling does not take into consideration oil spill response procedures being in place during the spill.

Chapter 19 Unplanned Events illustrates that the severity of the consequences of an oil spill depends on several factors including (a) type of oil spilled, (b) the amount of oil spilled and, perhaps most importantly, (c) the proximity of the oil spill to oil-sensitive resources. Whilst the probability of oil spillages is inherently low, the hydrodynamic modelling results as presented above indicates that such spillages in Russian waters have the potential to generate transboundary environmental impacts in other Black Sea countries (principally the marine waters of the Ukraine, Turkey and Georgia), with the significance of the impact being dependent upon the spillage volume and sensitivity of the release location.

Given that such hydrocarbon spillages have the potential to generate a transboundary marine environmental impact, the Project will implement a range of measures that aim to reduce the probability of such events occurring, as well as definition of actions to be taken following spillages to reduce potential environmental impacts (applicable to all Project phases). The oil spill prevention and mitigation strategy has been defined taking into account the findings of the hydrodynamic modelling (refer to Chapter 19 Unplanned Events) and includes:

- Marine diesel will be transported by supply Project vessels and vessels deployed in the Project Area will, where practical, use Marine Gas Oil (MGO) or MDO, commonly referred to as 'marine diesel' and conforming to ISO-8217:2010 Marine Distillate Fuel Grades DMA, DMB or DMZ. Therefore, any accidental spillages of fuel would have less adverse consequences than a spill that involved heavier fuels;

- Contractors working on behalf of South Stream Transport will be required to develop and implement an Oil Spill Prevention and Response Plan. South Stream Transport will ensure that contractor Oil Spill Prevention and Response Plans are appropriately aligned with the Black Sea Contingency Plan (Ref. 21.7);

- Contractors and operators of vessels working on behalf of South Stream Transport will operate in compliance with MARPOL regulations on oil spill prevention and response and are required to prepare Shipboard Oil Pollution Emergency Plans (SOPEP) and Shipboard Marine Pollution Emergency Plans (SMPEP) as applicable for each vessel (Ref. 21.8; Ref. 21.9). The SOPEPs will specify the control and response measures that have to be available on board every vessel in order to respond to a spill that does not require external intervention; and

- All marine vessel crews will have the appropriate training, qualification and certification to undertake the tasks required during the construction of the pipelines.
21.6.2.4 Invasive Species

Some of the vessels used by the Project will originate from locations outside of the Black Sea. Depending on the previous location of marine vessels (including the pipe-lay, support and supply vessels), there is a possibility that some vessels could introduce invasive species to the Black Sea via ballast water or fouling organisms on the vessel hulls. To mitigate against this risk, the following measures will be put in place where possible and practicable (also refer to Chapter 19 Unplanned Events):

- Where relevant and practical these measures will be based on those identified in the IPIECA (Global Oil and Gas Industry Association for Environmental and Social Issues) document Alien Invasive Species and the Oil and Gas Industry, Guidance for Prevention and Management and the International Maritime Organization (IMO) Ballast Water Management Convention and Guidelines. They will be applied to all marine plant and equipment that is used on the Project and which has the potential to be a vector of live organisms, spores, larvae and young and will include ballast water management, use of antifouling coatings, cleaning of equipment prior to deployment and the change of cooling water;
- Where practicable use anti-fouling coatings (non-TBT) or sealing coatings to minimise inadvertent transport of organisms;
- Where practicable, careful cleaning of hulls and tanks before use and prior to entering the Black Sea; and
- Vessels entering the Black Sea using ballast water exchange will, whenever possible, conduct ballast water exchange as far from the nearest land as possible, and in all cases at least 50 nautical miles (nm) from the nearest land and in water at least 200 m in depth.

With the implementation of such measures, no significant adverse impacts associated with transboundary invasive species are expected as a result of Project activities (applicable to all Project Phases).

21.6.2.5 Release of Gas

The only possible sources of large scale releases of gas into the atmosphere would be the result of a pipeline rupture or an unplanned need to vent gas from the pipeline (depressurise) to ensure overall system safety during the Operational Phase. Statistically a pipeline rupture is a very rare event and the probability of such an extreme situation is very low. Such events have been too infrequent for a meaningful analysis of frequency as based on historic industry data. As detailed in Chapter 19 Unplanned Events, the Project pipelines will be designed in compliance with national and internationally recognised standards, whilst the Project has developed specific design criteria taking into account Russian Federation design standards and international pipeline industry standards that aim to minimise the risks of pipeline failures which could result in large scale gas releases.

In the unlikely event of rupture of one of the pipelines during their operation, a shutdown sequence would be initiated via the emergency shutdown (ESD) valves at the landfall facilities or via from the central control room (CCR) in Amsterdam as soon as practicable (Chapter 5 Project Description). This would lead to closing of ESD valves at the Russian and Bulgarian landfall facilities. The shutdown sequence is part of the detailed process design of the pipeline.
system and is currently under development. After shut down, the pipeline may require depressurisation and gas may be vented at landfall facilities in Russia or Bulgaria to allow repairs to take place (see Section 21.5.2).

Gas will be trapped within the isolated pipeline with the exception of the point of rupture from which gas could escape. Any gas escaping the pipeline will partially dissolve in the water column and mainly flow to the surface, expanding during the ascent towards the surface of the sea. On contact with the water surface, gas will vent to the atmosphere. Depending on the volume of gas escaping the Pipeline, adverse effects to fish and marine life in general could occur. All impacts would, however, be localised within the area of rupture of the Pipeline because of the vertical route that any escaping gas would take after being released from the pipeline.

Given the above, unplanned releases of gas are not anticipated to have a transboundary environmental impact given that such events would only have localised impacts. However, pipeline shut down would result in the interruption to gas supplies in countries as serviced by the South Stream Offshore Pipeline.

Chapter 19 Unplanned Events details the design controls that have been included to reduce the likelihood of pipeline gas leakages.

21.7 Conclusions

21.7.1 Terrestrial Transboundary Impacts

Due to the distances between the Project and the land territories of Turkey, Georgia and Ukraine, planned activities and unplanned events do not have the potential to result in impacts that cross territorial borders and thus significant transboundary environmental impacts are not anticipated.

21.7.2 Marine Transboundary Impacts

Some planned Project activities have the potential to result in adverse marine transboundary environmental impacts given that Project activities will be taking place close to EEZ boundaries. However, defined mitigation strategies will mean that significant impacts on transboundary marine vessel movements, air quality, waste generation, invasive species, acoustically sensitive marine species, migratory birds, fish and fisheries would be avoided.

Some unplanned events involving the disruption or damage to subsea infrastructure, invasive species and hydrocarbon spillages (as a result of maritime accidents or collisions) have the potential to result in adverse marine transboundary environmental and socio-economic (e.g. disruption to telecommunications and gas supply) impacts. As such, the Project will implement a range of measures that aim to reduce the probability of such events occurring in the first instance, and define actions to be taken to reduce potential environmental and socio-economic impacts in the unlikely event of an unplanned marine incident.

22 Environmental and Social Management

22.1 Introduction

South Stream Transport is committed to develop and operate the South Stream Offshore Pipeline in an environmentally and socially responsible manner.

Further, South Stream Transport is seeking international financing for the Project, and consequently must meet the legal and other requirements of all countries through which it passes (i.e. the Russian Federation, Bulgaria and Turkey), plus adopted standards and guidelines for international financing1.

As the South Stream Offshore Pipeline will be constructed and operated as a single, coherent development across three countries, it will be managed by means of an overarching corporate management system. A Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS) will form an important part of the corporate management system. Key elements of the HSSE-IMS relating to environmental and social management are described in more detail in Section 22.5.

This chapter explains how commitments identified during planning stages (i.e. during national and international impact assessments) are captured in Environmental and Social Management Plans (ESMPs) that in turn form an important element of the HSSE-IMS.

22.2 Environmental and Social Commitments

Commitments in the form of design controls, safeguards, mitigation measures and monitoring requirements that aim to avoid, prevent, minimise or where this is not possible, offset potential adverse impacts and enhance positive impacts, have been identified or developed during the planning stages of the South Stream Offshore Pipeline. Figure 22.1 describes the key sources of environmental and social commitments, and their incorporation via a Master Commitments Register into ESMPs.

Thus, the Master Commitments Register represents the principal link and provides coherence between various source documents (including this ESIA Report) and the South Stream Offshore Pipeline ESMPs. As such, a single Master Commitments Register is compiled from sources from all three countries – Russia, Turkey and Bulgaria.

22.3 Environmental and Social Aspects and Impacts Register

South Stream Transport has evaluated environmental and social aspects for the South Stream Offshore Pipeline (i.e. for all three countries – Russia, Turkey and Bulgaria), and as a result has

1 Including the Equator Principles, OECD Common Approaches and IFC Performance Standards as outlined in Chapter 2 Policy, Regulatory and Administrative Framework of this ESIA.
prepared an Aspects and Impacts Register. This register lists environmental and social aspects and impacts based upon ENVIID, ESIA and Environmental Due Diligence Assessments, and identifies those that constitute a significant risk. These are subsequently transferred to the EIA/ESIA and Project Risk Register.

The purpose of ESMPs is to ensure that appropriate mitigation and monitoring measures are in place to deal with all significant potential environmental and social impacts of a project. The Aspects and Impacts Register therefore provides a focus for environmental and social management and development of the management plans for the Project and the overall South Stream Offshore Pipeline as shown in Figure 22.1.

**Figure 22.1 Inputs to Environmental and Social Management Plans**
22.4 Environmental and Social Management Plans

ESMPs are the principal means by which environmental and social impacts are managed and compliance with Project Standards is assured. ESMPs will be subject to regular review to determine adequacy and effectiveness and therefore, may be adjusted in line with the model described by ISO14001:2004 in order to improve future performance.

The ESMPs will form the basis for subsequent, more detailed management plans to be prepared and/or implemented by construction and operations contractors (see Section 22.5.4), who will be contractually obliged to comply with the relevant environmental and social requirements, specifications, and procedures set out in South Stream Transport ESMPs.

Consultation with stakeholders has been ongoing and will continue, including for disclosure of the ESMPs, as outlined in Chapter 6 Stakeholder Engagement.

22.4.1 ESMP Structure

The potential impacts are markedly different between Project phases, with many construction-related impacts ceasing during the Operational Phase. The HSSE-IMS will therefore include the development of phase-specific ESMPs:

- Construction Phase ESMP; and
- Operational Phase ESMP.

The Construction ESMP and the Operations ESMP will each comprise a suite of documents including a Framework Document and a set of management plans.

The document structure is shown in Figure 22.2.

**Figure 22.2 South Stream Offshore Pipeline HSSE-IMS and ESMP Structure**
22.4.1.1 Construction ESMP

The Construction ESMP will comprise an “ESMP (Construction) Framework Document”, a suite of activity-specific CMPs, and overarching CMPs. Between them, these documents will capture all relevant South Stream Offshore Pipeline commitments in terms of mitigation, management and monitoring actions defined in this ESIA and other documentation.

The ESMP (Construction) Framework Document will describe the Construction ESMP including its constituents and key linkages to other elements of the HSSE-IMS. In particular, it will set out the context and purpose of the activity-specific and overarching CMPs and will describe the rationale behind their development and how they will be implemented. This document will also include:

- A summary of the policies, legal and regulatory requirements and other applicable standards relevant to construction;
- Construction ESMP roles and responsibilities;
- Training requirements and standards;
- Performance indicators adopted;
- Inspection, audit and reporting strategies; and
- General instructions as to how the Construction ESMP should be used.

Activity-specific CMPs will be designed for identifiable discrete Project Activities (e.g. Russian Landfall activities). These plans will address environmental and social impacts that are likely to occur as a result of the relevant activities (e.g. noise emissions, air quality emissions, modification of ground conditions etc.).

As an example, the Russian Landfall CMP will address South Stream Offshore Pipeline commitments (mitigation, management and monitoring) applicable to all Russian onshore construction activities. It will cover microtunnelling works, onshore pipeline installation (as well as the permanent landfall facilities comprising a metering facility), pipeline inspection gauge (PIG) launch and trap facilities and emergency shut-down valve stations. It will also cover access roads, road transport to and from the landfall site and the Project’s interaction with Local Communities.

The activity-specific CMPs will contain activity-specific requirements to be met by both South Stream Transport and appointed contractors (and sub-contractors). The activity-specific CMPs will be developed for contractors as the primary users (as opposed to South Stream Transport personnel).

Figure 22.3 presents the activity-specific CMPs and overarching CMPs.
In addition to the activity-specific CMPs, it is recognised that some Project Activities are applicable to the South Stream Offshore Pipeline, independent of the location or nature of the activity in question.

The overarching CMPs, as shown in Figure 22.3, will address the South Stream Offshore Pipeline requirements, the majority of which will primarily be the responsibility of South Stream Transport.

22.4.1.2 Operations ESMP

The Operations ESMP will follow the same structure as the Construction ESMP, including both the development of an ESMP (Operations) Framework Document to describe the ESMP and key linkages to other elements of the HSSE-IMS, as well as a suite of activity-specific Operations Management Plans (OMPs) and overarching OMPs. The anticipated OMPs for the Operations ESMP are presented in Figure 22.4.

---

* Indicates plans that are not relevant to the Project (i.e. Russian Sector)

---

2 The overarching Stakeholder Engagement CMP is supplementary to the country Stakeholder Engagement Plans (SEPs) (see Chapter 6 Stakeholder Engagement) and will be implemented primarily by contractors. In particular it aims to ensure that any stakeholder engagement undertaken by contractors is aligned with South Stream Transport procedures.
Each OMP describes environmental and social mitigation, management and monitoring requirements and actions in relation to normal operating conditions and planned maintenance, minor repairs and minor incidents. Unscheduled major repair work relating to the offshore pipelines will be subject to permitting and impact assessment activities and development of bespoke management plans and procedures. Emergency situations will be covered by the separate emergency response plans and procedures described in Chapter 19 Unplanned Events.

Decommissioning activities will be covered by specific management plans to be developed during the Operational Phase.

22.4.2 ESMP Content

Each of the individual management plans within the ESMPs consists of two main components:

- Management and Mitigation Plan; and
- Monitoring Plan.

These two components are contained within the Appendices to each of the management plans. The main body of the management plans contains supporting information specific to the topic of the management plan including scope, responsibilities, linkages to other documents, implementation and verification and a summary policies and standards (including legal requirements).

22.4.2.1 Management and Mitigation Plan of ESMP

The Management and Mitigation Plan component captures all management and mitigation measures outlined in the source documents described in Figure 22.1. Those measures play a vital role in reducing the potential impacts associated with activities, and include:

- Design Controls: As part of the Project design process, measures to avoid or minimise impacts were identified and incorporated into the design. These are referred to as design controls and include design features and management measures. They are based on Good International Industry Practice (GIIP) and are intended to avoid or control unacceptable impacts. Specific design controls are described in greater detail in Chapter 5 Project...
**Description.** Their role in controlling impacts on environmental and social impacts is discussed more in *Chapter 3 Impact Assessment Methodology*; and

- Management and Mitigation Measures: Where the outcome of the ESIA indicates that design controls are insufficient to manage an impacts to an acceptable level, further measures have been identified. These measures have been termed “mitigation measures” and are described in respective chapters and detailed in Environmental and Social Management Plans.

**Management and Mitigation Actions**

The ESMPs provide a detailed list of mitigation measures and actions that are required to reduce to acceptable standards the adverse environmental and social impacts and enhance the positive impacts of the Project as presented in Section 22.4.

The management and mitigation measures are presented in a tabular format in the ESMPs (and associated CMPs) setting out the location and impact that each mitigation measure or action relates to, the entity responsible for implementing each measure or action, details of the mechanisms that will be used to monitor each measure or action and the performance criteria to be utilised in order to define or measure the success or failure of the measure or action.

**22.4.2.2 Monitoring Plan of ESMP**

The Monitoring Plan component of the ESMPs details the monitoring requirements based on the findings of this ESIA and other source documents (Figure 22.1) as applicable to the specific phase and activity or overarching topic.

For each of these monitoring requirements, the management plans specify:

- The parameters to be assessed as part of the monitoring;
- The proposed scheduling of monitoring activities;
- The proposed location of monitoring activities;
- The means of verification; and
- The roles and responsibilities for the monitoring activity.

In addition, South Stream Transport is developing a detailed overarching Environmental and Social Monitoring Programme for the South Stream Offshore Pipeline Project which will detail all monitoring requirements applicable to the South Stream Offshore Pipeline.

Monitoring is required in order to both demonstrate compliance with legal limits and South Stream Transport’s Project Standards as well as provide verification of the overall design and effectiveness of the implemented mitigation and management measures. The key objectives of South Stream Transport’s proposed monitoring activities are as follows:

- To monitor compliance with relevant standards and South Stream Transport’s environmental and social objectives;
- To provide an early indication of any mitigation and management measures or practices that are failing to achieve objectives;
To determine whether environmental and social changes are attributable to Construction and Operational activities; and

To provide a basis for continuous review of, and improvement to, the monitoring activities.

**Overarching Environmental and Social Monitoring Programme**

The monitoring plan requirements outlined in the ESMPs are defined in more detail in the overarching Environmental and Social Monitoring Programme. The overarching Monitoring Programme takes the monitoring requirements described in the ESMP monitoring plans and provides greater specificity and instruction on the monitoring locations, parameters to be monitored, sampling and storage methodologies, sampling frequency, analytical techniques and reporting.

In developing the overarching Environmental and Social Monitoring Programme, the following factors have been considered:

- Significance of environmental and social aspects identified through impact assessment;
- National legislative requirements;
- Good International Industry Practice (GIIP);
- Responsiveness to the detection of environmental and social changes or trends;
- Logistical practicality; and
- Cost effectiveness.

The following monitoring activities are likely to be included in the overarching Monitoring Programme for the South Stream Offshore Pipeline:

- Air Quality Monitoring;
- Noise Monitoring;
- Vibration and Seismicity Monitoring;
- Terrestrial Soils, Groundwater, and Surface Water Monitoring;
- Seabed Sediments and Marine Water Quality Monitoring;
- Biodiversity, Ecological and Natural Resources Monitoring;
- Solid and Liquid Wastes Monitoring (Onshore and Offshore);
- Landscape and Visual Amenity Monitoring;
- Land Use and Ownership Monitoring;
- Community, Local Economy and Traffic Monitoring;
- Cultural Heritage Monitoring; and
- Unplanned Events Monitoring.
22.4.3 ESMP Responsibilities and Implementation

South Stream Transport holds ultimate responsibility for the environmental and social performance of the overall South Stream Offshore Pipeline, including the performance of its contractors. Construction ESMPs will be implemented primarily via construction contracts and as appropriate will be issued to contractors who will be required to demonstrate how they will comply with the ESMPs through the development of their own contract-specific HSSE plans and procedures. These will be reviewed by South Stream Transport.

22.5 South Stream Offshore Pipeline HSSE-IMS

22.5.1 Introduction

As already described under the preceding sections of this chapter, the ESMPs – based on commitments raised in EIAs, ESIAs and other documents – form an important part of South Stream Transport’s HSSE-IMS. The HSSE-IMS, which provides the framework for implementation of the ESMPs, has been developed to align with the requirements of the two relevant international standards:

- ISO 14001:2004: Environmental management systems – requirements with guidance for use; and

In addition, the system has been developed to meet the requirements of an Environmental and Social Management System (ESMS) defined in International Finance Corporation (IFC) Performance Standard 1: Assessment and management of environmental and social risks and impacts (Ref. 22.1).

The main objective of the HSSE-IMS is to provide a robust framework for meeting the Project’s HSSE objectives during the entire Project lifecycle, from development to decommissioning. More specifically, the system has been designed to:

- Manage health, safety, security and environmental issues in an integrated manner;
- Clearly define the interface with other South Stream Transport management systems (e.g. quality assurance, corporate management system);
- Ensure high standards of management;
- Provide a mechanism to ensure that contractors meet South Stream Transport HSSE performance requirements;
- Establish procedures to allow South Stream Transport to monitor its HSSE performance and to report such information to its stakeholders;
- Provide South Stream Transport with a mechanism to meet its HSSE policy and associated corporate social responsibility (CSR) and sustainability goals; and
- Allow South Stream Transport to demonstrate to its stakeholders that it is committed to effective HSSE management through adopting the requirements of the relevant international standards.
The HSSE-IMS covers all persons employed directly and indirectly by South Stream Transport, including contractor and sub-contractor personnel.

The HSSE-IMS draws on the elements of the established business management process, outlined in IFC PS 1, of "plan, do, check, and act," which provides a methodological approach to managing environmental and social risks and impacts in a structured way on an ongoing basis. (Figure 22.5):

- **Plan** – Establish the objectives, and design the processes necessary to achieve those objectives and their associated targets;
- **Do** – Implement the plan and execute the processes;
- **Check** – Monitor implementation (usually through regular monitoring procedures or through audit), and analyse data against targets and requirements. Determine root causes of non-conformity where necessary, and design and implement corrective actions where required in order to achieve objectives and targets; and
- **Act** – Management Review of system performance to determine if policy, objectives and targets have been met, and where necessary to adapt these to reflect changing circumstances. The requirements of the system (e.g. organisational structure, resources and competence) that will enable it to achieve policy, objectives and targets, are also reviewed. The Management Review process concludes on the suitability, adequacy, and effectiveness of the management system, and decisions are made in order to improve the overall system.

**Figure 22.5 The Plan-Do-Check-Act Cycle**
The following sections provide a brief description of some of the key elements of the HSSE-IMS that are necessary to meet the HSSE objectives listed above and ensure implementation of the ESMPs.

### 22.5.2 Strategic Objectives and Targets

The approach to setting strategic HSSE goals by Senior Management is to define:

1. Annual strategic objectives and targets;
2. Performance Indicators (including Key Performance Indicators (KPIs)); and

Annual strategic objectives are set by Senior Management, with associated targets determined at the expert-level as appropriate. The objectives and targets support the CSR Policy and HSSE Policy, and are connected to significant aspects and impacts, and/or risks, related to the Project.

Performance indicators are defined to provide proactive and leading measures of HSSE performance over time. They act as a positive incentive for the delivery of the intended management tasks dictated by the HSSE-IMS to prevent incidents and adverse outcomes, and measure how well the HSSE-IMS is being applied.

A limited subset of the performance indicators related to key HSSE risk areas are selected as key performance indicators (KPIs). KPIs are limited in number in order to optimise performance monitoring, analysis and reporting by South Stream Transport and its contractors and to allow Senior Management to track headline HSSE performance in an effective and efficient manner.

Injury and other safety statistics are used to benchmark Project performance against industry or sector statistics for similar activities, e.g. oil and gas industry, offshore pipeline construction, etc.

### 22.5.3 Management System Structure

An overview of the HSSE-IMS document structure is shown in Figure 22.6.
Figure 22.6 HSSE-IMS Document Structure

Underpinning Documents
- HSSE Legal Register
- Project Environmental and Social Standards Document
- Environmental and Social Aspects and Impacts Register
- Project HSSE Competency Standards

Assessments and Analysis
- Design Risk Assessments (HAZID, QRA)
- Emergency risk analysis, crisis threat analysis
- Security threat analysis
- EIA / ESIA and ENVIID
- Environmental Due Diligence Assessments
- Arbo Risk Inventory and Evaluation
- HSSE Training Needs Analysis

Management Plans
- HSSE Objectives and Targets Plan
- Health and Safety Plan
- Environment and Social Management Plans
- Biodiversity Action Plan
- Stakeholder Engagement Plans
- Security Plan
- Occupational Health Plan
- HSSE Training Plan
- Office HSSE Plan
- Emergency Response Plan
- Crisis Management Plan

Technical Standards, Procedures and Guidelines
- Technical Standards
- Procedures
- Guidelines

Implementation Tools
- HSSE Information Management System
- Permits Compliance Tracking System
- Commitments Register
- Corrective Action Tracking System
- Stakeholder Consultation Database
- Interface Management Procedure
- Document Management System
22.5.4 Contract Management

South Stream Transport has developed a Contract Management Procedure. The procedure stipulates that contractors are held responsible as a condition of contract for the compliance of their workers and any subcontractors with the requirements of the HSSE-IMS and other relevant commitments defined in their tender. All contractors are required to provide their workers and subcontractors with the means to ensure compliance, e.g. information, instruction and training, work equipment and personal protective equipment.

The ESMPs, or relevant parts thereof, will be issued to contractors who will be required to demonstrate how they will comply with the ESMPs through the development of their own contract-specific plans and procedures.

Compliance will be assured through a range of means, including HSSE audits and inspections (pre-contract, pre-mobilisation, and during contract execution).

The contractors will develop an overarching HSSE Plan that describes how the CMP requirements will be met and provide cross-references to more detailed supporting plans prepared by the Contractor, or bridges to existing company or vessel plans and/or procedures.

Examples of detailed supporting plans, which contractors may develop or bridge to in order to meet the requirements of the CMPs include, but are not limited to:

- Reinstatement Plan;
- Chemicals and Hazardous Substances Management Plan;
- Integrated Waste Management Plan;
- Environmental Monitoring Plan;
- Traffic Management Plan;
- Fuel Delivery, Storage and Handling Plan;
- Emergency Response Plan;
- Spill Prevention and Response Plan;
- Training Plan;
- Dredging Management Plan;
- Anchor Management Plan;
- UXO Clearance Plan;
- Contamination Contingency Plan; and
- Ballast Water and Sediment Management Plan.

22.5.5 Emergency Response

South Stream Transport will prepare an Emergency Response Plan (ERP) for the South Stream Offshore Pipeline. South Stream Transport will work with its construction contractors to ensure that South Stream Transport and contractor plans are integrated with regional contingency
plans. Emergency Response Plans are discussed in more detail within Chapter 19 Unplanned Events.

### 22.5.6 Interface Management Procedure

South Stream Transport will interface with those companies responsible for the management of the Project’s associated facilities in order to coordinate and cooperate where possible on HSSE matters.

The Project’s associated facilities are described in Chapter 1 Introduction and comprise:

- Russkaya compressor station and the four pipelines connecting the compressor station with the Project, which are located immediately upstream of the Project in Russia and are being developed and managed by Gazprom Invest (GPI); and
- Designated existing quarries for sourcing material / aggregates, where those existing quarries would require significant expansion for the sole purpose of supplying the Project.

The most significant associated facility for the Project is the Russkaya compressor station and the pipeline linking the compressor station to the Project. South Stream Transport will use its best endeavours to influence GPI’s management of HSSE matters, encouraging compliance with the Project Standards of the South Stream Offshore Pipeline. To facilitate interaction with GPI, South Stream Transport has developed a HSSE Interface Procedure for the Russkaya compressor station which identifies parties within South Stream Transport and their counterparts in GPI with responsibility for management of HSSE and further establishes communication protocols between these parties in order to facilitate cooperation.

Where South Stream Transport has some level of control of environmental and social matters of an associated facility, South Stream Transport’s management measures will be detailed in the Project ESMP. Details of agreements between South Stream Transport and those entities that have management control of the associated facility will be documented in the Interface Management Procedure.

### 22.5.7 Management of Change

During the different phases of the Project, there may be a requirement to amend design elements or processes which results in a deviation from that presented in Chapter 5 Project Description. Accordingly, South Stream Transport has a management of change process to manage and track any such amendments which includes a screening process to identify potential environmental and social consequences.

Where a change has the potential to result in significant environmental and/or social impact it will be subject to a health, safety, security and environmental evaluation as part of the change management process, including review and revision of:

- Health, safety and environmental hazards and risks;
- Environmental aspects and impacts;
- Environmental and Social Management Plans;
• HSSE risk assessments, including updating of risk registers;
• HSSE mitigation measures and operational controls;
• Competency and training;
• Emergency preparedness and response; and
• Regulatory compliance.

For changes where a significant environmental and social impact is likely to arise, South Stream Transport will inform and consult with relevant parties on the nature of the impact and on proposed mitigation measures, where practical and appropriate.

All design changes will be added to a register of changes, which will summarise the change, the assessment, and the justification for South Stream Transport actions.

22.5.8 Performance Management

22.5.8.1 Audits and Inspections

HSSE performance will be assessed by a number of inspections and audits that are designed to identify positive implementation and also missing elements or non-compliance with the HSSE-IMS. Periodic inspections and audits will include:

• Marine vessel inspections;
• Site inspections and walkovers; and
• Internal (South Stream Transport) and external (third party) audits.

This will provide assurance that the requirements of the HSSE-IMS, including the ESMPs, have been met.

22.5.8.2 Corrective Action Procedures

Corrective actions are necessary to address new hazards or changes to hazards, inadequate implementation of control and mitigation measures, and non-compliances or non-conformances with the performance standards and requirements defined for the Project.

Corrective actions are identified from any of:

• Examinations, inspections and walkovers;
• Environmental and social monitoring;
• Meetings;
• Performance reviews and analysis;
• Observations made by workers or other parties;
• Incidents (and subsequent investigations);
• Near-miss or unsafe conditions;
• Emergency drills and exercises;
• Internal and external audits;
• Management Review of the HSSE-IMS; and
• Other communications.

All corrective actions that are not possible to implement immediately will be managed by a Corrective Action Procedure. The procedure is supported by a Corrective Action Tracking Register (CATR), through which appropriate corrective and preventative actions are documented, tracked and closed-out.

22.5.9 HSSE Reporting

The format and protocols for HSSE reporting is specified by the HSSE-IMS, which requires periodic internal and external reporting. Reports will be prepared for a range of stakeholders, including Project Lenders, and will range from weekly contractor HSSE reports to annual Project HSSE reports (in which the findings of more frequent reports are consolidated). Reports necessary to satisfy applicable law, regulations and permits will also be produced.

Annual Project HSSE reports will provide an annualised summary of HSSE performance against objectives and targets, performance indicators and industry benchmarks, together with supporting information on the implementation of the HSSE-IMS.

22.5.10 Management Review

The HSSE-IMS is subject to an annual review to comprehensively assess HSSE performance and the continued effectiveness and relevance of the HSSE-IMS to the Project, and to encourage continual improvement in the management system and HSSE performance overall. The management review is carried out by Senior Management in consultation with the Project HSSE Manager and based largely on the findings of monitoring, inspections and audits described in Section 22.5.8.

..................................................23-4
23 Conclusions

This chapter summarises the conclusions of the impact assessment undertaken for the Project. It provides a holistic view of how the ESIA was undertaken, how the Project has committed to avoiding, mitigating and managing risks and impacts so that development opportunities are enhanced, and provides a summary of impact assessment conclusions for each technical discipline.

23.1 Meeting ESIA Objectives

South Stream Transport is committed to implementing Good International Industry Practice (GIIP) in relation to environmental and social performance during Project Construction and Pre-commissioning, Operational and Decommissioning Phases. The Project is being carried out in accordance with standards and guidelines for international financing, including those for Environmental and Social Impact Assessment (ESIA). As described in Chapter 2 Policy, Regulatory and Administrative Framework (Section 2.7), applicable standards and guidelines include: the International Finance Corporation (IFC) Performance Standards (PS), Equator Principles (EP) III, the OECD Common Approaches, and the Japan Bank for International Cooperation (JBIC) Guidelines for Confirmation of Environmental and Social Consideration. In accordance with these standards and guidelines, this ESIA has met the necessary requirements for an assessment and management of environmental and social risks.

Chapter 1 Introduction demonstrates that the South Stream Offshore Pipeline will respond to the increased European demand for foreign natural gas by providing an overall export capacity of 63 bcm/year, which will be directed to the European supply network. This additional capacity, which is the primary benefit of the Project, is estimated to be between 11% and 18% of total projected European imports in 2035. Without the Project, this positive benefit to society may not be met.

Chapter 4 Analysis of Alternatives presents an analysis undertaken of technically and financially feasible alternatives, which were analysed in the context of the engineering, environmental, socio-economic and cultural heritage constraints carried out during the Feasibility and Development Phases of the Project. The requirement to provide flexibility to construction contractors in determining the most efficient and cost-effective construction methods whilst ensuring compliance with Project standards and Project commitments drove this process. To some extent, the nature and location of the Project was determined by factors beyond the control of South Stream Transport, particularly in respect of the location of the landfall section which was constrained by the selection and siting of the Russkaya compressor station (CS). Due to the fact that a majority of the Project is located offshore, the water depth and the physical characteristics of the Black Sea present a challenge for the Project and have influenced a number of key technical decisions, including the routing of the pipelines.

---

1 Based on Wood Mackenzie (2013) estimates. International Energy Authority (2013) estimates suggest this could be between 14 – 22% of the EU’s demand for natural gas in 2035.
**Chapter 5 Project Description** provides a detailed description of the Project, and has formed the basis for the assessment of Project Activities. Baseline information is presented in each technical chapter (Chapters 8 - 18) of this ESIA Report. Key receptors within each technical Study Area are identified and their characteristics described in each technical chapter also.

This ESIA Report has been prepared taking into consideration the definition of Project Area of Influence provided by IFC Performance Standard 1. The Project Area of Influence includes those areas likely to be affected by the main Project Facilities and Associated Facilities, and in the case of cumulative impacts, incremental impacts from other developments unrelated to the Project that will take place within the vicinity of the Project Area and within the Project timescale of implementation.

### 23.2 Stakeholder Engagement

Stakeholder engagement (including dialogue, consultation and the disclosure of information) is a key element of project planning, development and implementation. Effective stakeholder engagement assists good design, builds relationships with local communities, and reduces the potential for delays through the early identification of risks and issues.

South Stream Transport is committed to a transparent and respectful dialogue with stakeholders throughout the life of the Project. Within each phase of the Project, a range of engagement activities have been and will be undertaken to address the needs of different stakeholders and stakeholder groups.

**Chapter 6 Stakeholder Engagement** describes South Stream Transport’s approach to stakeholder engagement, its purpose, and the regulatory context in which it occurs. It provides information about engagement activities undertaken to date for the EIA and ESIA processes and those that are planned for the future. The chapter also summarises the comments that have been made by stakeholders to date and how these comments are addressed within the relevant chapters of this ESIA Report.

A Stakeholder Engagement Plan (SEP) has been developed and a Grievance Procedure will be implemented by South Stream Transport in partnership with its contractors to ensure that grievances are brought to the attention of the appropriate Project staff and addressed in an appropriate and timely way. The Grievance Procedure describes the process by which a grievance is received, recorded and managed so that it can be tracked from its original submission through to a resolution with the affected stakeholders.

The Project's approach to stakeholder engagement considers both regulatory requirements and principles of GIIP, and seeks to:

- Meet the legal requirements of the Russian Federation for public consultation and disclosure during the EIA process (described in Chapter 6 - Section 6.2.1);
- Align with international standards and guidelines for financing (and GIIP), as related to ESIA, that provide a framework for public consultation and disclosure during the ESIA process (described in Chapter 6 - Section 6.2.2); and
- Align with international conventions and protocols relevant to stakeholder engagement for the Project (described in Chapter 6 - Section 6.2.3).

Effective engagement has facilitated the establishment of an active and positive relationship between stakeholders and the Project proponent, South Stream Transport. The most common topics raised during consultations to date included:

- Concerns about the Project’s potentially negative impact on the natural environment including marine environment, the coastline and onshore habitat area;
- Local residents felt that gas transported by the Project should be supplied to the Local Communities located near the proposed Pipeline;
- Concerns about the safety of the Project and what measures would be put in place in an emergency situation;
- Various social related issues including anticipated Project impacts on Local Communities and visiting tourists;
- Concerns about the potential impacts of the Project in relation to increased traffic and on the quality of roads and access routes;
- Questions about the Project location, pipeline routing and alternative options considered;
- Queries about the EIA and ESIA processes;
- Questions about how the Project is engaging with stakeholders and ensuring issues and concerns are being taken into consideration; and
- Enquiries about whether local jobs would be created by the Project and how people could apply.

23.3 Impact Assessment Conclusion

The ESIA process is a systematic approach to identifying the potential environmental and social impacts of a development proposal, and to describing the mitigation, management and monitoring measures that will be implemented to address those impacts. Ultimately, it allows relevant parties to make informed decisions about a development proposal, and allows potentially affected stakeholders to participate in the process. The impact assessment has been based on the methodology presented in Chapter 3 Impact Assessment Methodology. Credible impacts to the key receptors were in general assessed using an impact significance matrix approach that considers the sensitivity of the receptors and the magnitude of the impacts. Impacts due to unplanned events, and due to cumulative and transboundary impacts, were also considered.

Impact significance was assessed with and without mitigation measures in place. The assessment of impact significance without mitigation measures in place took into consideration Project design controls. It is pertinent to note that impacts without mitigation measures in place are not representative of the Project’s actual extent of impact, and are described in this ESIA Report to facilitate understanding of how and why mitigation measures were identified.
Chapter 23 Conclusions

The residual impact is what remains following the application of mitigation and management measures, and thus represents the final level of predicted impact associated with the development of the Project. A summary of the residual impacts is presented below.

23.3.1 Overview

After implementation of design controls, management and mitigation measures, the residual environmental and social impacts of the Project, are generally of Not Significant to Low significance. The three exceptions which are above Low significance are presented in Table 23.1 below.

Table 23.1 Summary Table of Residual Impacts Above Low Significance

The following sections provide additional detail.
23.3.2  Soils, Ground Water, and Surface Water

Impacts to soil may result through the use and storage of materials, land clearance and earthworks. With mitigation measures in place, including standard soil and erosion control measures and the provision of adequate spill prevention, the residual impact to soils is concluded to be of low significance. This applies to the Construction and Pre-Commissioning Phase, and to the Operational Phase of the Project, and includes Landfall Section of the Project Area.

Impacts to groundwater quality and dynamics may result through use and storage of materials, groundwater control, the mobilisation of existing contamination due to earthworks, and hydro-testing. Through mitigation, including the implementation of a Spill Prevention and Response Plan, residual impacts to groundwater are considered to be of low significance. This applies to the Construction and Pre-Commissioning Phase, to the Operational Phase, and to the Decommissioning Phase of the Project.

Impacts to surface water in the landfall section of the Project Area may result through use and storage of materials, surface water run-off across disturbed soils and river crossings (by the pipeline and access road). Impacts during the Operational Phase are not anticipated. Through mitigation, the residual significance of the impacts is reduced to Not Significant to Low.

23.3.3  Air Quality

Project emissions will result from a number of area, point and mobile sources. These include emissions of combustion gases from construction vehicles and plant, diesel generators and marine vessels. There will also be dust generated from earth works and vehicles movements. Emissions from other sources e.g. small releases from vents during maintenance are also likely during the Operational phase of the Project, although such emissions will be minimal and/or infrequent. Consequently, the impacts during operation are anticipated to be of negligible magnitude, resulting in an impact that is Not Significant.

The air quality assessment has therefore focussed on Construction Phase impacts utilising established air quality modelling techniques and conservative assumptions to estimate Project derived air quality impacts. The assessment studies, taking account of potentially affected receptors and existing baseline conditions, concluded that air quality impacts associated with the Project are typically of Not Significant or Low significance for all pollutants.

Despite the Project’s minor impact on air quality, a number of good practice mitigation measures will be implemented to minimise air emissions. Monitoring will also be undertaken during the Construction Phase to confirm that ambient air quality remains within applicable limits for the protection of human health.

During the Construction Phase the Project may emit significant quantities of greenhouse gases (GHG). South Stream Transport will therefore put in place a monitoring plan to quantify the Project’s GHG emissions during the Construction Phase.
23.3.4 Noise and Vibration

An assessment of the worst case noise and vibration impacts associated with construction has been undertaken. The results predict that noise and vibration impacts will be Not Significant at existing sensitive receptors neighbouring the Project, with the exception of Receptor 4 (a cluster of residential dwellings on the north-eastern part of Varvarovka), where a High impact is predicted. The Receptor 4 location is mainly affected by road traffic noise using the Varvarovka Bypass Road, and the High impact significance is only predicted to occur during periods when the greatest vehicle movements will occur. Mitigation in the way of a noise screen is proposed along the boundary of the Varvarovka Bypass Road. Post mitigation noise impacts are predicted to be of Low significance.

The assessment at a proposed residential site (Receptor 5 – known as the Lesnaya Polyana Development Site and described in Chapter 14 Socio-Economics), has indicated that noise impacts may be High. It is however, anticipated that this location will not be developed and occupied by residents before the Construction Phase has been completed. Therefore, the impact significance at this location is also considered to be Not Significant. If occupation occurs during the Construction Phase, adequate mitigation measures will be investigated to reduce noise levels to meet the identified criteria.

Assessment of the cleaning, gauging and drying pre-commissioning activities has concluded that that the majority of receptors would experience a High impact during the pre-packing period when the booster compressors are used. By selection of inherently quiet plant, careful siting, and the use of acoustic bunds/barriers it is feasible to reduce noise impacts to Low impact significance. These impacts would be temporary and short term in nature.

Vibrations impact significance was assessed to be Not Significant during the Construction Phase.

The assessment of the Operational Phase concluded that noise and vibration impacts will be Not Significant.

An assessment of decommissioning activities will be undertaken during the Operational Phase of the Project when conditions and receptors at that time are known. However, it is anticipated that decommissioning works can be suitably mitigated so that the impacts are of Not Significant to Low significance.

23.3.5 Terrestrial Ecology

The Project has the potential to affect designated sites (Utrish State Nature Reserve, Kuban River Delta Ramsar Site, and the Delta of the Kuban River Important Bird Area – although the footprint of the Project does not intercept any of these), natural habitats (as defined by IFC PS6), and a number of species listed on the IUCN Red List, the Red Data Books of the Russian Federation and Krasnodar Krai (including notably, Testudo nikolskii or Nikolski’s tortoise, an internationally Critically Endangered species).

Impacts which have been identified as likely to occur at the Construction and Pre-commissioning Phase include habitat loss and degradation, direct mortality, injury, and disturbance to individuals of species, and habitat fragmentation or severance. Impacts are
Chapter 23 Conclusions

however anticipated to be either avoided, through consideration of ecological receptors in the Project’s design and/or, where appropriate, through implementation of mitigation measures (including provision of a Biodiversity Action Plan (BAP)) which will reduce the magnitude of all impacts to low – negligible levels. The residual effects on all receptors, regardless of their sensitivity, will therefore be either **Not Significant** or of **Low** significance.

The assessment also considered the potential for the Project to affect terrestrial ecology receptors during the Commissioning and Operational Phase of the Project. Although impacts during this phase are anticipated to be relatively limited, there is the potential for the Project to have impacts of up to moderate significance, in the absence of mitigation. This is due to the potential for routine maintenance activities to cause mortality or injury to Nikolski’s tortoise and other herpetiles. Mitigation measures have been proposed which will reduce the magnitude of all impacts at the Operational Phase on all receptors to either **Not Significant** or **Low** significance.

While it is not possible now to fully assess the effect of decommissioning the Project, the ESIA has considered two scenarios in this regard: in situ abandonment and pipe recovery, considering that the former generates impacts broadly similar to those of the Operational Phase, while the latter generates impacts broadly similar to the Construction Phase. It is, therefore, assumed that if mitigation measures are implemented which are broadly similar to those proposed for the Construction and Operational Phases of the Project, the residual effect on all receptors for decommissioning will be **Not Significant**.

Consideration has been given to the requirements of the IFC's PS6, particularly in relation to the identification and consideration of critical habitat. A Critical Habitat Assessment has been undertaken which has identified a number of ecological receptors which qualify as components of critical habitat. In accordance with IFC PS6, mitigation measures (including provision of a BAP) have been proposed and will be implemented to achieve a net biodiversity gain for these receptors.

**23.3.6 Marine Ecology**

The Black Sea is the world’s largest anoxic basin. This condition is due to the presence of a permanent pycnocline at around 150 to 200 m water depth that limits the vertical exchange of water between oxic surface waters and anoxic deeper waters creating a unique chemical and biological environment. Waters with hypoxic or entirely anoxic conditions are typically incapable of sustaining permanent populations of species dependant on aerobic respiration.

The ESIA considered potential impacts to main habitat types (viz. soft substrate benthic habitats and seaweed stands in oxic and suboxic waters of the shelf, and microbial communities mainly in the anoxic waters of the abyssal plain), and to species grouped according to plankton, benthic communities, fish, seabirds, and marine mammals, and included the conservation status of designated areas and species. Construction and Pre-Commissioning activities have the greatest potential to impact marine ecological receptors, particularly benthic communities. Residual impacts to benthos are reduced to **Low** or **Not Significant** through various project design controls and mitigation measures, including strict adherence to relevant environmental standards, the choice of technology and comprehensive environmental management. Noise
impacts associated with construction activities are very short term and unlikely to cause mortality or injury to marine mammals and so have a Low significance.

Potential impacts during the Operational Phase relate to the presence of the pipeline on the seabed directly and indirectly affecting habitat structure, as well as disturbance due to inspection and maintenance activities. These predominately have the potential to be moderate impacts prior to mitigation. Operational impacts are largely mitigated through ensuring the stability of the pipe on the seabed and through control of vessel activities during inspection and maintenance. These mitigation measures will reduce operational and commissioning impacts to marine ecological receptors to Low. Decommissioning impacts are anticipated to be similar to those in the Construction Phase.

The occurrence of critical habitat was determined in accordance with IFC guidance. The Project Area lies within some Tier 2 critical habitat, which was identified according to IFC criteria for endangered, migratory and congregatory species (namely certain pelagic fish, seabirds and cetaceans). It should be noted that the Project Area does not, per se, represent particular habitat that is not replicated elsewhere in the Russian Black Sea; it is merely part of a wider zone that meets the requisite criteria. Because the Project does not have the scope or scale to impact such extended areas, the assessment of impacts relating to critical habitats has focussed on the species for which that habitat is considered critical rather than the habitat itself. After mitigation measures are in place, a monitoring and research programme will enable the Project to meet IFC PS6 requirements for net gain.

23.3.7 Landscape and Visual

The landscape and visual impact assessment concluded that during the Construction and Pre-Commissioning Phase of the Project the residual effects on the Undulating Plateau landscape character area (CA) will be Moderate, and on the Black Sea Coastal seascape CA will be Low. There will be five Moderate adverse residual effects, seven Low adverse effects and one Not Significant effect on potential visual receptor groups.

The five visual receptor groups identified with significant (Moderate or above) residual effects are visitors to the Russian Orthodox and Armenian cemetery at Varvarovka, residents living at North-East Varvarovka, walkers on the coastal path along the cliff top, recreational visitors to the seashore and recreational boat users.

These impacts will typically be short-term and indirect, during the Construction Phase, which could be further reduced by consultation with the affected parties to better assess the receptor sensitivity and more accurately gauge the magnitude of the potential impacts.

During Construction and Pre-Commissioning Phase, it is considered that visitors to the Russian Orthodox and Armenian cemetery at Varvarovka, and residents living at North-East Varvarovka, will potentially experience the major impacts associated with the Project. These impacts are direct and permanent but could potentially reduce with the establishment of the proposed mitigation planting vegetation.
Chapter 23 Conclusions

The residual impacts for landscape character and visual amenity during the Operational Phase will be **Not Significant to Low** following the implementation of design controls and mitigation measures. No significant impacts are expected during the Decommissioning Phase.

### 23.3.8 Socio-Economics

In terms of economic related impacts, the assessment has identified that the Project will result in limited temporary beneficial economic impacts as a result of the additional employment and increased demand for goods and services during the Construction and Pre-Commissioning Phase. In the longer term, it has also identified beneficial economic impacts at a national level associated with an increase in revenues for both the Russian gas industry and the Russian Federal government, due to the increase in Russian gas exports that the Project will enable.

During the Construction and Commissioning phases, there is the potential for **Low adverse** economic impacts prior to mitigation on Shingari and Don Holiday Complexes, and the Anapa Resort Town tourism sector, due primarily to impacts on the coastal area amenity that may affect customers of these two businesses, and thereby potentially reduce revenues for the businesses. A Fisheries Study (see Appendix 14.1 Fisheries Study) has concluded that it is unlikely that there will be any distinguishable impact on fish stocks or on the fishing industry in general (individual employment or local business impacts) due to construction of the Project in the nearshore and offshore sections. Accordingly, the impact on the fishing industry would be **Not Significant**. The requirement by the Project for land on both a temporary and permanent basis will also result in **Low adverse** impacts due to the take up of Agrifirm Kavkaz (Fond Yug) vineyards and associated potential economic displacement of vineyard workforce activity.

The application of mitigation, including ongoing stakeholder consultation, the Grievance Procedure and, if applicable, access to the Compensation Framework would result in a **Not Significant** residual impact on Shingari and Don holiday complexes and also on the Anapa Resort Town tourism sector. The Grievance Procedure (and, if applicable) the Compensation Framework would also apply in terms of the fishing industry and the workforce of Agrifirm Kavkaz (Fond Yug) vineyards as a result of the take up of land. Additionally, a Livelihood Restoration Framework would also apply as mitigation. Given the potential for impacts on livelihoods, it has been considered that the residual impact magnitude would remain **Low**.

There is also the potential for a moderate adverse pre-mitigation impact on the Varvarovka Horse Riding Business, in a worst-case scenario if that businesses’ access to a riding route is interrupted or severed. However if the worst-case scenario does occur, the application of mitigation including the Compensation Management Framework and Livelihood Restoration Framework, would reduce the impact significance to **Low adverse**. With regard to community-related impacts, the construction of the Project may also result in **Low adverse** significance adverse residual impacts on Sukko beach and Shingari beach users, and also on the amenity experienced by visitors to the Varvarovka village cemetery. During the Construction and Pre-Commissioning Phase, there is the potential for amenity-related impacts on residents as a result of noise and visual impacts. With the application of mitigation, as set out in noise and visual impact assessments, these impacts can be partially mitigated. However, **Moderate adverse** residual amenity-related impacts are still expected to be experienced by residents in the North East of Varvarovka for a short period of time.
During the Operational Phase, there would be beneficial economic impacts at a national level in terms of increased demand for Russian goods and services (gas) and increased government revenues, taxes and royalties. There would not be any adverse residual socio-economic impacts associated with the Project during the operational phase.

With regard to Human Rights, there were no significant adverse potential impacts identified that cannot be mitigated through adherence to policies, plans and procedures, as well as through community engagement. Furthermore, the Due Diligence process recognises that the Human Rights risks may change over time as the Project evolves from the Construction and Pre-Commissioning Phase into the Decommissioning Phase. As such, the Project’s Human Rights Due Diligence is an iterative process whereby business operations and operating context will be examined on a regular basis.

23.3.9 Community Health, Safety and Security

The Construction and Pre-Commissioning Phase of the Project will bring direct employment opportunities to Local Communities at the landfall facilities. Procurement of goods and services will also give rise to indirect employment across a wider area. This local employment is relatively small in number and while the effects will also be small they will be beneficial. The people who are employed and their families and dependents could enjoy improvements to their health and wellbeing through increased wealth and socio-economic status.

The infrastructure and logistics requirements of the Project mean that there are inevitably some adverse effects for certain population groups. Large construction sites and busy transport corridors can be disruptive for Local Communities and can contribute to negative health outcomes.

South Stream Transport will take appropriate measures to reduce disruption through design controls and other mitigation measures that will govern the movement of transport, noise from Project vehicles and noise from Project plant. The Project will also maintain communication with Local Communities to ensure that any grievances are addressed promptly.

The community health, safety and security assessment identified that following the implementation of design controls and mitigation measures, one residual impact of **Low** to **Moderate** significance remained during the Construction and Pre-Commissioning Phase: road safety impacts due to increased traffic as a result of construction on the main road running through the community of Rassvet.

Noise impacts on residential dwellings in parts of Varvarovka due to traffic on the proposed Varvarovka Bypass Road and from the use of the compressor spread are considered to have a Low significance of health effect.

No significant impacts were identified during the Operational Phase of the Project which will bring economic benefits to the Russian Federation, which could translate into greater expenditure on infrastructure and initiatives that directly or indirectly improve health across the nation. South Stream Transport’s commitment to ongoing consultation with local communities is expected to provide reassurance regarding Project operations, with potential anxieties decreasing as the Project’s track record for safety becomes established and is publicised.
23.3.10 Cultural Heritage

The Construction and Pre-Commissioning Phase of the Project has the potential to impact the terrestrial cultural heritage receptor RU-TCH-02, RU-TCH-06 (Varvarovka village cemetery, Armenian and Russian cemetery). Through the use and application of mitigation measures such as the Cultural Heritage Management Plan and an Archaeological Watching Brief, the residual impacts will reduce to Not Significant to Low. No residual impacts on terrestrial receptors are expected during the Operational or Decommissioning Phases of the Project.

The Construction and Pre-Commissioning Phase has the greatest potential to impact marine cultural heritage receptors. However, with the implementation of Project design controls and mitigation measures, including careful routing to avoid and minimise impacts on sensitive marine cultural heritage, many impacts are reduced to Not Significant to Low with the exception of two Cultural Heritage Objects which will have Moderate residual impacts due to the fact the 150 m minimum distance cannot be met and one CHO will need to be relocated.

The exception is disturbance to currently unknown marine archaeology which remains at having the potential for not significant to high adverse impacts. However, with implementation of the Archaeological Chance Finds Procedure, the residual impact will minimise impact significance.

Operational and Commissioning Phase impacts relate to offshore and nearshore sections. Prior to mitigation, these are potentially moderate to high impacts. However, operational impacts are largely mitigated through avoidance by protective buffering, tether management, minimising propeller or thruster washing and avoiding ROV strikes by careful piloting. These mitigation measures will reduce residual impacts to marine cultural heritage receptors to Not Significant.

23.3.11 Ecosystem Services

The values which ecosystem service beneficiaries attached to ecosystem goods and services are appropriately considered and addressed throughout the ESIA process.

The assessment identified five priority services which the Project is likely to impact during the Construction and Pre-Commissioning Phase: crops; soil quality regulation; tourism and recreational values; cultural and spiritual values; and wild species diversity. No priority services were identified for the Operational Phase.

Mitigation measures are identified and are intended to anticipate and avoid, or where avoidance is not possible, minimise impacts on receptors. Assuming that the mitigation measures are successfully implemented, it will be possible for the Project to mitigate all potential adverse effects associated with the Project to the degree that residual impacts would be of Not Significant to Low significance.

Hazard regulation was identified as an additional priority service during the Decommissioning Phase if the second option for decommissioning (i.e. removing the pipeline) is selected. However, as the approach has not yet been decided and due to the large degree of uncertainty of assessing impacts over this timeframe, appropriate mitigation will be determined based on a survey of the risks nearer the time of decommissioning. The combined effects of the Project and other developments are not expected to result in any significant cumulative impacts on ecosystem service beneficiaries.
23.3.12 Waste

The assessment identified the waste streams that are anticipated to be produced during the Construction and Pre-Commissioning Phase and during the Operational Phase, and identified the availability and suitability of existing waste management facilities to manage those wastes. Mitigation measures have been recommended in order to minimise the impacts as far as possible, including an Integrated Waste Management Plan for the entire Project.

Moderate impacts are estimated in the event that the existing Alfa landfill is used for disposal of non-hazardous wastes from the Project. It is expected that this landfill will be closed and a replacement, engineered facility may be available by 2016. Even in the absence of such a facility, the relatively small amounts of non-hazardous waste requiring landfill means that the impacts of using Alfa Landfill would be Not Significant.

Provided that all of the mitigation measures are implemented, the overall waste management impacts from the development will be Not Significant.

23.3.13 Unplanned Events

Unplanned events are episodes that are not expected to occur during the Project’s normal construction and operational phase activities, such as accidents. As such, the environmental and social consequences of an unplanned event, should it occur, can often be significant.

This ESIA has followed a systematic approach to identify a number of unplanned events, primarily related to marine accidents and loss of pipeline integrity, with the potential to cause significant environmental and social impacts. In order to manage unplanned events efforts must be made to minimise the likelihood of an unplanned event occurring in the first instance. The Project has, therefore, adopted the following approach:

- Use design controls based on GIIP to minimise the likelihood of an incident; and
- Develop response measures in case of an unplanned event.

This ESIA details a number of modelling studies undertaken to predict the likelihood of unplanned events (marine spills, pipeline rupture, fires) and concludes that the probability of such significant events is low and below the levels specified by industry acceptance criteria. Nevertheless, a suite of emergency response plans is being developed by South Stream Transport and its contractors to enable a rapid response in the unlikely event of an incident with the potential to result in adverse environmental and/or socio-economic impacts. The plans will contain measures to minimise the impacts of unplanned events including: measures for oil spill prevention and response; medical provisions; fire-fighting and; the use of pipeline exclusion zones and measures designed to enhance workers’ well-being and thereby minimise potential worker or civil conflicts. The Project’s emergency response plans will be integrated with regional and national plans as necessary.

23.3.14 Cumulative Impact Assessment

Chapter 20 Cumulative Impact Assessment provides an assessment of potential cumulative impacts. The assessment follows recent IFC guidance to determine the potential for
the Project’s impacts to interact with those of other projects/developments (spatially and/or temporally) in a manner that could result in significant cumulative impacts. The cumulative impact assessment (CIA) includes consideration of the Russkaya CS (which is defined as an associated facility) and a number of residential and mixed use developments that are reasonably defined and in the vicinity of the Project.

The Project has relatively few and/or minor impacts during the Operational Phase of the Project, whilst the other developments scoped into the CIA are almost exclusively onshore. Consequently the CIA largely focusses on the potential for cumulative impacts associated with the Project’s onshore construction activities. Where possible the CIA draws from existing development plans and impact assessment studies, notably the EIA prepared for the expansion of the United Gas Supply System which includes an assessment of the Russkaya CS.

The CIA considered the potential for cumulative impacts in each of the technical disciplines where the Project has the ability to generate impacts and therefore could contribute to a cumulative impact. Consequently the CIA considered potential cumulative impacts upon soils, groundwater and surface water; air quality; noise; terrestrial and marine biodiversity; landscape and visual receptors; socio-economic impacts (including beneficial impacts); ecosystem services; cultural heritage; waste; and land-based traffic.

The results of the CIA did not identify any adverse environmental or social cumulative impacts that are considered to be significant, principally due to the degree of mitigation being proposed by South Stream Transport for the Project.

In addition to the above, given that the Russkaya CS development is defined as an associated facility, a separate collective appraisal was undertaken which considered the potential impacts of the Project and the Russkaya CS development as though they were one development. This collective appraisal highlighted a number of areas where the alignment of mitigation approaches and the integration of mitigation and management plans would be advantageous with regard to reducing potential collective environmental and social impacts. South Stream Transport will use the findings of the collective appraisal to discuss opportunities for the aligning the mitigation and management approaches with Gazprom Invest.

### 23.3.15 Transboundary Impact Assessment

The potential for the Project to generate potential transboundary impacts during planned activities has been assessed. This included an assessment of the implications on air quality due transportation activities, impacts due to waste generation, impacts due to the propagation of underwater noise on fish and marine mammals, and impacts on migratory birds and fish. Chapter 21 Transboundary Impact Assessment discusses each of these in turn and does not identify any significant transboundary impacts associated with these planned activities.

An assessment has also been undertaken of the potential for transboundary impacts due to unplanned events, including the severance of transnational subsea infrastructure, marine accidents resulting in oil spills that could affect Russia’s neighbouring Black Sea countries, the inadvertently introduction of invasive alien species into the marine environment and potential unplanned gas releases. Some unplanned events (e.g. oil spills) do have the potential to cause significant transboundary impacts, however the risks are considered to be acceptable because
of the measures in place to minimise the likelihood and consequence of such incidents. The Project will also apply applicable international guidelines designed to prevent the transboundary movement of invasive marine species.

In addition, the Project pipelines will be designed in compliance with national and internationally recognised standards, whilst the Project has developed specific design criteria taking into account Russian Federation design standards and international pipeline industry standards that aim to minimise the risks of pipeline failures which could result in large scale gas releases.

23.4 Environmental and Social Management

As described in Chapter 22 Environmental and Social Management, a Health, Safety, Security and Environmental Integrated Management System (HSSE-IMS) will form an important part of South Stream Transport’s corporate management system. The potential impacts are markedly different between Project phases, with many construction-related impacts ceasing during the Operational Phase. The HSSE-IMS will therefore include phase-specific management plans. Environmental and Social Management Plans (ESMPs) have been developed to capture design controls, safeguards, mitigation measures and monitoring commitments made within the ESIA. Adherence to these plans will be a condition of any Project construction and operation contracts awarded.

23.5 Summary

As set out in South Stream Transport’s Health and Safety, Security and Environmental Policy, South Stream Transport is committed to environmentally and socially responsible management, in accordance with applicable national, international (including EU legislation), and internationally recognised standards for health and safety, security and environmental and social performance. This corporate policy applies to all staff and across all business activities, it guides strategy, management, decisions and actions, it is incorporated into the documents governing relationships with suppliers and contractors, and guides relationships with joint venture and other business partners.

The Corporate Social Responsibility and Sustainability Policy further expresses South Stream Transport’s commitment to integrating social, economic, environmental and governance considerations into the everyday conduct of business during the design, build and operation of the South Stream Offshore Pipeline.

These policies thus underpin South Stream Transport’s commitments to systematically avoid and reduce the potential for adverse environmental and social impacts associated with the Project, or where this is not possible to compensate and offset impacts on receptors. South Stream Transport is committed to ensuring appropriate monitoring and management plans are in place to address these impacts and this will be done through the HSSE-IMS and ESMP processes, as well as continual stakeholder engagement through the life of the Project. Assuming that the mitigation measures identified in this assessment are successfully implemented, it will be possible for the Project to mitigate most adverse effects associated with the Project to the degree that the majority of impacts after mitigation would be Not Significant or Low.
